Among the minor adjuncts in electric lighting, an important part in guarding against possible risk of fire is played by the 'cut-outs,' whose function is to interrupt the current in any main or branch conductor should it ever exceed a safe strength—as might happen in the event of an accidental cross-connection or short-circuit being formed between the wires. The usual form of cut-out is a safety fuse, consisting of a short piece of foil or wire made of lead or of some fusible alloy which any dangerous excess of current will melt, and so interrupt the current, in that portion of the system which is guarded by the cut-out, before any damage is done. Cut-outs are generally put at the junction of branch with main wires, as well as in the mains themselves. Where the amount of current to be passed is large, an electro-magnetic cut-out is often preferred to a fuse.

Numerous forms of *meter* have been devised for measuring and recording the quantity of electricity supplied to consumers, some suited for continuous currents only, and others for alternating as well as continuous currents. Space does not admit of any description of the ingenious meters invented by Ferranti, Aron, and others. In Edison's meter for continuous currents, which has done good service in central station lighting on the parallel system in New York, the amount of electricity which passes is measured by the deposit of metal in an electrolytic cell. In Forbes's meter, which acts equally well with continuous or alternating currents, the current heats a small coil of wire so that a stream of warm air rises from it; this is made to turn a little windmill, whose number of revolutions is registered, and is found to be a good index of the amount of current which has passed.

*References.*—The literature of electric lighting consists mainly of papers published in the scientific and technical journals, for the most part since 1878. In the article DYNAMO-ELECTRIC MACHINES (q.v.) reference has already been made to Professor S. P. Thompson's treatise on *Dynamo-electric Machinery*. A lecture by the same author (*Journal of the Society of Arts*, March 1889) gives a comprehensive account of various types of arc lamps. Much descriptive and historical matter regarding dynamos and arc lamps will be found in *Electric Illumination*, by J. Dredge. Reference should also be made to papers by J. Hopkinson, 'On some Points in Electric Lighting,' *Inst. Civ. Eng. Lectures* (1883); 'On Transformers,' *Proc. Royal Society* (1887); by G. Kapp, 'On Transformers,' *Proc. Soc. of Telegraph. Engineers* (1888), and 'On Alternate Current Machinery,' *Min. Proc. Inst. Civ. Engineers* (1889); by G. Forbes, 'On the Distribution of Electricity,' and 'On Electric Meters,' *Journal of the Society of Arts* (1885, 1886, and 1889).

**Electric Railway.** The proposal that electricity should furnish motive power on railways is nearly as old as the railway-system itself. In 1837, when it was still doubted whether steam locomotives would come into general use, an

experiment in electric traction was made by Robert Davidson, who propelled a car on the Edinburgh and Glasgow Railway by an electro-magnetic engine, with a galvanic battery to supply the current. But the cost of producing electricity on a large scale by means of a battery is so great as to make such a method of locomotion impracticable, however perfectly the electric energy may afterwards be converted into mechanical work. And the electro-magnetic motor of those days was an extremely inefficient machine, which did not succeed in utilising more than a small fraction of the electric power supplied to it. The matter consequently fell into complete abeyance, and was not revived until engineers had at their command a much cheaper mode of producing electric energy, and a much more efficient mode of turning it to mechanical account. This came about with the introduction of the Dynamo-electric Machine (q.v.), which gave a cheap means of converting work done by a steam-engine or any other prime mover into the electrical form, and with the recognition that the operation of the dynamo was reversible—that it would serve as a motor, to do mechanical work by the agency of the electric current. Hence it became practicable to work a railway electrically, by having at one station a dynamo to produce the current, driven by a steam-engine, turbine, or any other source of power, and by using this current to drive another dynamo, as a motor, upon the train, electrical connection between the train and the source of supply being maintained by means of conductors with which the train should be kept in contact throughout its course.

This was first demonstrated on a practical scale at the Berlin Exhibition of 1879, by Werner Siemens, who made and worked with complete success a line 219 yards long, on which three carriages, carrying twenty people, ran at a speed of about 7 miles an hour, by means of the current from a fixed dynamo, which was driven by a steam-engine. The current reached the car through a special conducting rail placed between the wheel-rails, and insulated from the ground by blocks of wood. The motor on the car took the current from this rail by the rubbing contact of copper brushes, and the circuit was completed through the car wheels and the ordinary rails. In 1881 a permanent electric tramway, 1½ mile long, was established at Lichterfelde (Berlin), where a still simpler plan of conducting the current was employed; the two ordinary rails, insulated from the ground and from one another by wooden sleepers, formed the two conductors. Soon after that a number of electric tramways or railways were constructed in various parts of Europe, and a still greater number in the United States, where, at the end of 1888, there were nearly 150 miles at work: one of those lines (at Montgomery, Alabama) is as much as 11 miles in length.

The plan of using the rails themselves as the only conductors is obviously impracticable, except on very short lines and in special circumstances, on account of the difficulty of maintaining good insulation. In some of the most important existing lines a special stiff conducting rail is used, raised from the ground on insulating supports. The Portrush and Bushmills Railway in Ireland (opened in 1883) is an instance in point. There the line is 6 miles long, the dynamos that supply the current are placed at a station about a mile from it, and are driven by water-power. The same plan is followed at the Bessbrook and Newry Railway (1885), where passenger-cars, on which the motors are placed, serve as locomotives to drag a train of goods-wagons. The trains run at a speed of about 10 miles an hour, and the expenses of working are from 3d. to 4d. per train-mile. A

stiff conductor, set along-side of the rails, is also used for electric traction on some portions of the New York elevated railroads. In a few cases the conducting rail is put in a trench underground—an arrangement which allows this system to be applied to city tram-lines. But in by far the greater number of electrical railways or tramways, especially in America, the conductor is a wire carried on posts overhead, either immediately above the cars or along-side of them. In many instances the current is taken from the overhead conductor by means of a little carriage running on it, and drawn along by the car. An extremely simple overhead system has been suggested by Dr. Hopkinson, in which the conductor is a wire, or stand of wires, supported by means of posts, so that it hangs slack over the line, at such a height that a metal rod, fixed on the top of the car, rubs against it. There are two rods—one near the front of the car and the other near the back—and these keep up continuity of contact as the car passes under the supports, from one to another of the slack spans in which the conductor hangs.

When there are several motor cars running on an electric railway at the same time, they are commonly arranged in electrical 'parallel'—that is to say, the motor of every train forms a cross connection between a single pair of positive and negative conducting mains. If, however, the line be divided into a sufficient number of short sections, it is possible to run the trains in electrical 'series,' each train spanning a gap in an otherwise continuous conductor, and the same current passing through all in succession. This plan, which has the advantage of requiring a smaller volume of current (but at a correspondingly greater potential), was patented by Fleming Jenkin in 1882. It is used on an electric tramway which was opened at Northfleet in 1889, where the insulated sections of the conductor are carried in a trough underground.

All the arrangements for electric traction that have been referred to above are *conductor* systems. Energy is continuously passing to the car through the conductor which maintains connection between the distant dynamo and the motor on the car, and any break of continuity in the conductor, or any failure on the part of the car to make contact with it, deprives the car instantly of locomotive power. The introduction of storage batteries (see *ELECTRIC LIGHT*) has made a very important alternative method of electric traction practicable—viz. the *storage* system, in which each car or train is self-contained as regards power. In this system there are no conductors along the line, but each locomotive is furnished with a set of storage cells, which are charged from time to time by means of a station dynamo, and carry enough energy to last during the trip. The storage system has been put in practice at Antwerp, Hamburg, Brussels, New York, London, and elsewhere, in some cases by placing the cells under the seats of the car, in others by using a separate locomotive car to carry them and the motor. For city tram-lines its advantages are obvious: it makes each car independent, it causes no obstruction of the street by troughs or posts to carry conductors, and it allows existing lines to be utilised for electric traction without change. Its chief drawbacks are the dead-weight of the batteries and the cost of renewing those when they are worn out or injured by the rather rough treatment they receive on the road. In conductor and storage systems alike there is a considerable loss of energy in the successive transformations, amounting generally to 40 or 50 per cent. On short lines this waste should be less when conductors are used; but on long lines the

loss which is caused by the resistance of the conductors may be greater than the loss which the charging and discharging of a battery entails.

An important feature in conductor methods of electric traction is the possibility they afford of applying an absolute automatic block system, so as to make it impossible for trains to overtake one another, without any control being exercised from the trains themselves. When the line is divided into sections, it is possible to arrange matters so that the presence of a train on one section has the effect of cutting off the supply of electric energy to the section behind, and thus a train entering the latter finds itself unable to proceed until the train in front has advanced to the section beyond. A number of plans by which this idea may be carried out have been invented by Fleeming Jenkin and by Ayerton and Perry. Fleeming Jenkin, too, it was who proposed the word *Telpherage*, as a distinctive name for electric traction developed on these lines. In one of his systems of telpherage, suitable for transporting minerals or goods in small parcels and at a low speed, the line consists of a series of short spans of steel cable, supported overhead upon stout posts, at a distance of some 70 feet apart. The train is a number of light cars, which hang from the line; they are free to swing, and are spaced and connected together by light coupling rods. A telpher line of this construction, about a mile long, was erected in 1885 at Glynde, in Sussex. The trains carry cement clay in small skips or buckets, and travel at a walking pace without driver or guard.

**Electric Telegraph.** See TELEGRAPH.

**Electric Welding.** See WELDING.

**Electro-biology** is a term used both of Animal Electricity, discussed at ELECTRIC FISHES, and of Mesmerism, or a phase of Animal Magnetism (q.v.).

**Electrolysis.** See ELECTRICITY.

**Electro-magnetism.** See MAGNETISM.

**Electro-metallurgy** is the art of depositing, electro-chemically, a coating of metal on a surface prepared to receive it. It may be divided into two great divisions—electrotype and electroplating, gilding, &c., the former including all cases where the coating of metal has to be removed from the surface on which it is deposited, and the latter all cases where the coating remains permanently fixed. Gold, platinum, silver, copper, zinc, tin, lead, cobalt, nickel, can be deposited electrolytically.

**Electrotype** is the art of copying printing type, woodcuts, seals, medals, engraved plates, ornaments, &c. by means of the galvanic current in metal, more especially copper. Suppose we wish to copy a seal in copper; an impression of it is first taken in gutta-percha, sealing-wax, fusible metal, or other substance which takes, when heated, a sharp impression. While the impression—say, in gutta-percha—is still soft, we insert a wire into the side of it. As gutta-percha is not a conductor of electricity, it is necessary to make the side on which the impression is taken conducting; this is done by brushing it over with plumbago by a camel-hair brush. The wire is next attached to the zinc pole of a weakly charged Daniell's cell, and a copper plate is attached by a wire to the copper pole of the cell; or, as is now usual, the current required is supplied by Dynamo-electric Machines (q.v.). When the impression and the copper plate are dipped into a strong solution of the sulphate of copper, they act as the — and + electrodes. The copper of the solution begins to deposit itself on the impression, first at the black-leaded surface in the vicinity of the connecting wire, then it gradually creeps over the whole conducting surface. After a day or two on the old method—

after a few hours when the magneto-electric is used—the impression is taken out; and the copper deposited on it, which has now formed a tolerably strong plate, can be easily removed by inserting the point of a knife between the impression and the edge of the plate. On the side of this plate, next the matrix, we have a perfect copy of the original seal. If a medal or coin is to be taken, we may proceed in the same way, or we may take the medal itself, and lay the copper on it. In the latter case, the first cast, so to speak, that we take of each face is negative, showing depressions where the medal shows relief; but this is taken as the matrix for a second copy, which exactly resembles the original. The adhesion between the two is slight, and they can be easily separated. The cell of a battery is not needed to excite the current.

A galvanic pair can be made out of the object to be coated and a piece of zinc. The figure shows how this may be done. B is a glass vessel containing sulphate of copper; A is another, supported on B by a wire frame, and containing a weak solution of sulphuric acid. The glass vessel A is without a bottom, but is closed below by a bladder. A piece of zinc, Z, is put in the sulphuric acid, and a wire, D, coated with insulating varnish, establishes a connection between it and the impression, C, which is laid below the bladder. Electrotype is of the greatest importance in the arts; by means of it duplicates in copper of pages of type are obtained, as is done with this Encyclopedia; engraved copper plates may be multiplied indefinitely, so that proof-impressions need be no rarity; woodcuts can be converted into copper; bronzes can be copied; and similar like applications are made of it too numerous to mention. By connecting a copper plate ready for corrosion with the + pole, and making it a + electrode, it can be etched with more certainty than with the simple acid, and without the acid fumes.

**Electroplating.**—This is the art of coating the baser metals with silver by the galvanic current. It is one theoretically of great simplicity, but requires in the successful application of it very considerable experience and skill. Articles that are electroplated are generally made of brass, bronze, copper, or nickel silver. The best electroplated goods are of nickel silver. When Britannia metal, iron, zinc, or lead are electroplated, they must be first electro-coppered, as silver does not adhere to the bare surface of these metals. Great care is taken in cleaning the articles previous to electroplating, for any surface impurity would spoil the success of the operation. They are first boiled in caustic potash to remove any adhering grease; they are then immersed in dilute nitric acid to dissolve any rust or oxide that may be formed on the surface; and they are lastly scoured with fine sand. Before being put into the silvering bath, they are washed with nitrate of mercury, which leaves a thin film of mercury on them, and this acts as a cement between the article and the silver. The bath where the electroplating takes place is a large trough of earthenware or other non-conducting substance. It contains a weak solution of cyanide of silver in cyanide of potassium (water, 100 parts; cyanide of potassium, 10 parts; cyanide of silver, 1 part). A plate of silver forms the + electrode; and the articles to be plated, hung by pieces of wire to a metal rod lying across the trough, constitute the — electrode.

When the plate is connected with the copper or + pole of a one or more celled galvanic battery, according to the strength required, or subjected to the magneto-electric current, and the rod is joined with the zinc or - pole, chemical decomposition immediately ensues in the bath, the silver of the cyanide begins to deposit itself on the suspended objects, and the cyanogen, liberated at the plate, dissolves it, re-forming the cyanide of silver. According, then, as the solution is weakened by the loss of the metal going to form the electro-coating, it is strengthened by the cyanide of silver formed at the plate. The thickness of the plate depends on the time of its immersion. The electric current thus acts as the carrier of the metal of the plate to the objects immersed. In this way, silver becomes perfectly plastic in our hands. We can by this means, without mechanical exertion or the craft of the workman, convert a piece of silver of any shape, however irregular, into a uniform plate, which covers, but in no way defaces, objects of the most complicated and delicate forms. When the plated objects are taken from the bath, they appear dull and white; the dullness is first removed by a small circular brush of brass wire driven by a lathe, and the final polish is given by burnishing. The process of electro-gilding is almost identical with that of electroplating. Success in either is attained by proper attention to the strength of the battery, the strength of the solution, the temperature, and the size of the + electrode. See George Gore's *Electro-metallurgy* (1877) for a sketch of the art—from Wollaston's application of the principle of the voltaic pile to the deposition of one metal upon another (1801), on to subsequent application of that principle by Bessemer (1834), Jacob (1838), Spencer (1839), and the Elkingtons (from 1838 onwards).

**Electrometer.** See ELECTRICITY.

**Electromotive Machines.** See DYNAMO-ELECTRIC MACHINES, MAGNETO-ELECTRICITY.

**Electrophorus,** an instrument for obtaining electricity by means of induction. It generally consists of a tin mould, A, which in practice is kept

Electrophorus.

in connection with the ground, filled with shell-lac or resin, B, and a movable metal cover, C, with a glass handle, D, as shown in the fig. The shell-lac is poured in when melted, and is mixed with some other substance to make it less brittle. When the apparatus is used, the surface of the resin or the shell-lac is smartly beaten with cats' fur. This electrifies the resin negatively. When the cover is brought near the lower part of the apparatus, it is charged positively on its under surface, negatively on its upper. If then it is touched, the negative escapes, and the cover is charged with + electricity; and if removed and applied to any conductor, it will give a positive charge to it. The process may be repeated for a great number of times with only a small diminution of B's charge, except by connection or dampness. It is usual to have the earth

connection made by a metallic pin passing through B to A, or by a piece of tinfoil, e, pasted extending slightly over B, and connected with A.

**Electroplating, Electrotpe.** See ELECTRO-METALLURGY.

**Electrum** (amber; Gr. *ēlektron*) is a term also applied to native gold as it is associated with silver.

**Electuary,** a form of medicinal preparation in which the remedy is enveloped or suspended in honey or syrup, so as to make a thick, semi-fluid mixture.

**Elegit.** In England, a judgment creditor may elect to have a *Fieri Facias* (q.v.) to the sheriff to levy the debt, or that the sheriff should deliver to him the land (and formerly the goods) of the debtor. If he chooses to seize the land, he does so under a writ of elegit, and so long as he remains in possession he is tenant by elegit. The writ was formerly used chiefly for seizing chattels; but in most cases it was a less convenient remedy than a *Fi. fa.*

**Elegy** (Gr. *elegia*), according to its derivation, signifies a song of lamentation, but the term was employed at an early period by the Greeks to designate any poem written in distichs. The alternation in elegiac verse of hexameter with pentameter helps to give to this species of poetry its character, which consists in the connection of subjective feelings and emotions with external incidents or objects. Many poems have been written in this form which are not elegies proper. Of the numerous elegies of the Greeks, few have come down to us. Among the Romans, Catullus was the first good elegiac writer; after him came Propertius, Tibullus, and Ovid. Tibullus, in particular, brought the erotic elegy to its highest perfection. In modern times, the term elegy is applied in England to any serious piece where a tone of melancholy pervades the sentiments, as in Gray's famous *Elegy, written in a Country Churchyard*. It includes also such splendid tributes to the dead as the *Lycidas* of Milton, the *Adonais* of Shelley, the *In Memoriam* of Tennyson, and the *Thyrsis* of Matthew Arnold. See *The Book of British Elegies*, by W. F. M. Phillips (1879).

**Elemental Spirits,** beings who, according to the popular belief of the middle ages, presided over the four 'elements,' living in and ruling them. The elemental spirits of fire were called Salamanders; those of water, Undines; those of the air, Sylphs; and those of the earth, Gnomes. Paracelsus wrote a treatise upon them, and they play a part in Pope's masterpiece of mock-heroic poetry, *The Rape of the Lock*.

**Elements,** in Astronomy, are those numerical quantities, and those principles deduced from astronomical observations and calculations, which are employed in the construction of tables exhibiting the planetary motions. They include the greatest, least, and mean distances of the planets from the sun, the eccentricities of their orbits, their mean motions, daily and annual, with the motions of their aphelia, and the inclinations of their orbits to the ecliptic; their masses and densities, &c. See PLANETS, PLANETODES, &c.

**Elements,** CHEMICAL, the simplest known constituents of all compound substances. Chemists regard as elementary substances or elements only those substances which have not been proved to be compound. It is not inconceivable that some of the substances at present designated elements (for list of known elements, see ATOMIC THEORY) may hereafter be proved to consist of more than one simple kind of matter, but in the meantime they are correctly called elements, as that term is

applied above. The elements are somewhat arbitrarily divided into non-metals and metals, the latter forming by far the larger class. There is no sharp line of demarcation between the two classes, several elements occupying positions on the border line. The elements commonly classed as non-metals are thirteen in number, and are as follows: Hydrogen, chlorine, bromine, iodine, fluorine, oxygen, sulphur, selenium, boron, nitrogen, phosphorus, carbon, silicon. Hydrogen, however, in its chemical relations behaves like a metal. Speculation at present is on the whole rather favourable to the view that all the elements are composed of one fundamental elementary substance (see also CHEMISTRY, and METALS). The time-honoured 'Four Elements' of the Greeks—air, fire, water, earth—are discussed at EMPEDOCLUS. The 'Shoo-king,' a Chinese work older than Solomon, has five elements—water, fire, wood, metal, earth. The Indian Institutes of Manu have also five—subtle ether, air, fire, water, and earth.

**Elemi**, a fragrant resinous substance, is obtained from the pitch-tree, *Arbol de la Brea*, a native of Manilla. Formerly, many varieties of elemi, such as Mexican, Brazilian, and Mauritian elemi, were in the market, but these have now been supplanted in Great Britain by the original substance, that obtained from Manilla. Manilla elemi, when pure and fresh, is colourless, and resembles in consistency old honey, but it is usually found mixed with impurities, hard, and of a yellow tint. It possesses an aromatic odour resembling that of a mixture of lemon, fennel, and turpentine, and when distilled, yields as much as 10 per cent. of essential oil. When treated with cold alcohol, it partly dissolves, leaving about 20 per cent. of a white resinous substance called Amyrine. Elemi is never used internally, and only seldom as a stimulating ointment to old wounds.

**Elephant**, a genus of mammals in the order Proboscidea, now represented only by two species. These two survivors of a once numerous and widely distributed order occupy a zoological position of peculiar isolation, but they are connected by the

Indian—are quite distinct from one another, and are sometimes referred to separate genera (fig. 2). Like other giant animals, they are becoming gradually restricted in distribution and numbers, a fact of course hastened by the demand for the ivory of their tusks.

**Principal Characters.**—In some of their structural features, especially in nose, skull, and teeth, the elephants are as highly differentiated as they are in general intelligence; while on the other hand the anatomy of their limbs and anterior venous system is simple and primitive. The huge size, thick skin, and scanty hairs; the enormous head with high rounded skull containing large air-spaces and with wide expanse for the insertion of muscles; the long, muscular nose or proboscis with the nostrils at the tip; the short stiff neck which makes the trunk such an advantage; the huge simple limbs and massive feet, are conspicuous features. The brain is not much larger than man's, but as one would expect from the elephant's cleverness, is richly convoluted; the hind portion or cerebellum is, however, uncovered like a rabbit's. The teeth consist (1) of a pair of enormous, ever-growing upper incisors or tusks, composed mainly of the precious dentine or ivory; and (2) of the large plated molars, the final result of a long series of historical differentiations, six on each side above and below, but never represented by more than one in full use at a time. The upper parts of the stout limbs are very long, so that the knees especially are situated far down; the five toes are inclosed in a common hoof which is very massive, the circumference of the fore-foot measuring about half the height at the shoulder. More technical characters are the presence of two superior ventrals, the simple stomach and large cæcum, the abdominal situation of the male organs, the two-horned uterus, deciduate zonary placenta, and the position of the two teats upon the breast. The diet is vegetarian, and the animals are gregarious. An elephant may weigh 3 to 4 tons, and live 120 years, though the average seems to be about eighty.

**The Two Species.**—The Indian Elephant (*Elephas indicus*) is now restricted to the forest-lands of India and south-east Asia, including Ceylon and Sumatra. The African Elephant (*E.* or *Loxodon africanus*) inhabits the greater part of the African continent south of the Sahara. The contrast between the two species may be indicated as follows:

INDIAN.	AFRICAN.
Ears of moderate size.	Ears $3\frac{1}{2}$ feet long by $2\frac{1}{2}$ feet broad.
Molar teeth with folds parallel.	Lance-shaped folds.
Trunk ends in finger-shaped upper lobe.	Loops of trunk apex nearly equal.
Concave forehead.	Arched forehead.
Four or five nails on the hind-foot.	Three nails on the hind-foot.
Male, about 10 feet at shoulder.	Males about a foot higher.

For extinct forms such as the Mammoth (*Elephas primigenius*), nearly allied to the Indian species, for the ancient British forms, for the Pigmy Elephant (*E. melitensis*), and for even more gigantic forms than the two species now alive, the reader is referred to the articles MAMMOTH and MASTODON.

**Habits: Food.**—The elephants use their trunks in gathering leaves, branches, and herbage, which they pass dexterously to the mouth. The Indian elephant eats the leaves of the palm, fig, and jak trees, &c.; the African form is fond of the succulent mimosa. Most kinds of palatable vegetable food, from sugar-canes to cocoa-nuts, are acceptable. Those brought to Britain are largely fed on hay and carrets. They prefer forest and mountainous regions; are ready to plunder rice and other crops, but seem to have a wholesome dread of fences.

Fig. 1.—African Elephant ('Jumbo').

extinct Mastodon and Dinotherium to Coryphodon and the Dicerata, and further back still to a probable origin among primitive hoofed or ungulate animals. The modern elephants—African and

*Drinking.*—Without bending head or limbs, the elephant dips the end of the trunk into the water, and fills it by a strong inspiration. The trunk is

Fig. 2.—Heads of (A) African and (B) Indian Elephants.

then inserted into the mouth and forcibly emptied. In the same way water or even sand may be blown over the body for cleaning and cooling the skin.

*Locomotion.*—The general leisurely and heavy tread of the elephant can be changed into a very fast trot or peculiar shuffle, especially when the

Fig. 3.—Tips of Trunks of (a) African and (b) Indian Elephants.

males furiously charge their rivals or enemies. Their slow but sure progress is found most serviceable in difficult mountain travelling. Though one would hardly

expect it, they undoubtedly have considerable powers of swimming. 'A whole herd has been known to swim without touching bottom for six consecutive hours, rest a while, and then swim three more, with one rest.' When a herd with young ones is forced to take to the water, the mothers hold some up with their trunks, while others find a more comfortable position on their mothers' backs.

*Herding.*—Elephants are conspicuously social, a habit which has doubtless directly influenced their intellectual development. The herds are usually family parties; the mothers and young go in front, the males bring up the rear. The positions are reversed in alarm and danger. Both family likeness and family sympathies are often strongly marked. The leader is obeyed and also protected with much *esprit de corps*.

*Breeding.*—The males of both species are rather larger than the females, and excel in strength, endurance, and in the greater development of the tusks. A male is on this last account valued at one-fifth more than a female. In some localities—e.g. Ceylon, the female incisors remain very small, and the disproportion is always more marked in the Indian species. The male elephant is polygamous, and usually rules alone in the herd, expelling or killing his rivals. By means of such habitual contests the tusks have doubtless been perfected in strength. Except at the breeding season, the adult males live much by themselves, probably for selfish reasons rather than from love of solitude. At pairing-time a gland opening on the side of the head, between eye and ear, becomes especially active in the adult males, which are then said to be in 'must,' and are

then well known to be probably the most dangerous of animals. The gland secretes a substance of strong musk-like odour, and is one of the numerous secondary sexual characters exhibited by animals. The fragrance is probably attractive to the female sex, though this must be a subsequent advantage, and not in any way a cause of the development of such an organ. 'The elephant,' Darwin observed, 'is reckoned the slowest breeder of all known animals, and I have taken some pains to estimate its probable minimum rate of natural increase: it will be under the mark to assume that it begins breeding when thirty years old, and goes on breeding till ninety years old, bringing forth three pair of young in this interval; if this be so, at the end of the fifth century there would be alive fifteen million elephants, descended from the first pair.' It is obvious enough that mortality and enemies, especially man nowadays, obviate any approximation to even such slow, natural increase of numbers. The elephant is one of the best examples of Spencer's law of the inverse ratio of individuation and rate of reproduction. Endless stories are told of the savageness of 'rogue' elephants, which seem chiefly to be males who have been expelled from the herd, and have in part the savageness of Ishmaelites, and in part the madness of enforced celibacy. The mothers manifest much maternal affection and care. One young elephant is born at a time, though occasionally twins may occur. There is a long (20½ months) period of gestation. The elephant sometimes breeds in captivity. Even after twenty years of menagerie life, birth is said to have occurred. In Siam and other parts of the East, breeding studs are kept up, but recruiting by fresh captives is always necessary. One of the baby Asiatic elephants born in America weighed 245 lb. at birth, and was about the size of a sheep. It took milk for six months, and afterwards began to eat tender grass. The sucking is done as usual with the mouth, not with the trunk.

While the tusks of the male are much used in the customary contests with rivals, they serve other purposes. Thus Darwin notes: 'The elephant uses his tusks in attacking the tiger; according to Bruce, he scores the trunks of trees until they can be thrown down easily, and he likewise thus extracts the farinaceous cores of palms; in Africa he often uses one tusk, always the same, to probe the ground, and thus ascertain whether it will bear his weight.' The tusks are also used in ploughing the ground in search of bulbs. According to the position and curvature of the tusks, he either 'flings the tiger to a great distance—it is said to even 30 feet, or endeavours suddenly to pin him to the ground'—an action dangerous to the rider, if there be one, who is apt to be jerked off the howdah.

The trunk can be used in endless ways, to pull down a tree or snip a bunch of grass, to lift an immense weight or a pin from the ground, to fight or to fondle. Through it they make a loud shrill sound described by Aristotle as resembling the hoarse noise of a trumpet.

*Intelligence.*—Though the eyes are very small, they are quick to discern, and the other senses are highly developed. The elephants are also social animals. These two conditions, always favourable to intellectual development, are certainly here associated with a high degree of intelligence. Their memory both for friends and foes is strong, and has been more than once remarkably illustrated by tamed elephants, which, having escaped and been recaptured, returned with all their old obedience to their keeper. In higher mental qualities elephants are only excelled, according to Romanes, by dog and monkey. By dexterous blowing, an elephant made a potato, which had fallen out of reach,

rebound against the opposite wall so as to return to an accessible place. Darwin observed similar experiments in the Zoo. Their dexterity in assisting human labour, their quiet submission to operations, the gusto with which decoys practise deceit, the manner in which they thatch their backs in summer to keep off sun and flies, their selection, shaping, and dexterous use of pieces of wood (implements) for leech-scrapers, fans, &c., their discriminating way of lifting and handling different materials according to their hardness, sharpness, (abstract ideas), &c., are all remarkable. To pile up materials round the base of a tree, so as to make a platform from which to reach an otherwise inaccessible enemy, shows decided power of rational device. An elephant has been known to feign death, and the working tamed forms are said to have an accurate sense of time. Of their capacity for learning tricks little need be said; to take tea at a table and ring for the waiter, to uncork bottles and drink the contents, or even to salute princes, puts more strain upon the elephant's patience than upon his intellect.

*Emotions.*—The elephant may be extremely gentle and affectionate, or when injured, both passionate and vindictive. They readily form friendships with their keepers, with children, or with fellow-animals, and sometimes manifest quite human tenderness. The partnership between the wild elephants and the birds which pick insects from their skin and rise screaming when alarm threatens, is obviously not disinterested. The better emotions, such as sympathy, appear undoubtedly to predominate, but there is no doubt as to their proverbial vindictiveness. The classic story of the tailor and the elephant has been repeatedly verified, in some cases with tragic results. As peculiarities of emotional temperament, Romanos notes the following: 'If a wild elephant be separated from its young for two or three days, though giving suck, it never after recognises or acknowledges it. The members of a herd are exclusive, a strayed stranger is driven off, and may thus become a "rogue" or "goondah." Such an Ishmaelite undergoes a transformation of disposition, becoming savage, cruel, and morose. He is possessed not by sudden bursts of fury, but by a deliberate brooding resolve to wage war on everything, and lies patiently in wait for travellers.' Elephants are also subject to sudden death from what the natives call a 'broken heart,' and which seems in some cases at least referable to psychical or cerebral conditions.

*White Elephants.*—Albines occur among elephants as in other animals. In these the colouring matter of the skin is deficient; but the adjective white can hardly be used to describe the result. Their rarity has made them valuable, and they are revered as incarnations of Buddha. Holder notes that in the 16th century Pegu and Siam fought over one for many years, till five successive kings and thousands of men were killed, while Barnum in 1883 bought one in Siam which cost him \$200,000 by the time it reached America. Elephants vary slightly in the amount of hair on their characteristically naked hides. Those on high cool regions in India are said to have rather more hair, thus approaching the woolly extinct species of long past Arctic climates.

Atropos of Barnum, an elephant-craze of modern times was illustrated in regard to an elephant named Jumbo, which had at least an eventful history of travel. Born in Central Africa, sold to the Jardin des Plantes in Paris, thence to the Zoo in London, and thence in 1882 to Barnum for \$10,000 in spite of outcry and petitions, shipped with some difficulty to New York, and killed by a railroad car in Canada—such is in brief the life-

history of an animal which secured an unusually large share of popular attention. Its remains—skin and skeleton—were presented to two American museums.

*Hunting.*—The elephant is hunted either for captivity, work, and pageantry, or for the sake of its ivory. The Indian forms are often captured alive in numbers by organised parties of four hundred or so natives, and the process is both tedious and costly. The herd is surrounded, and the circle narrowed by fires and watching. A strong fence and moat are made to form the so-called 'kheddah' into which the elephants are driven. There they are separated and hobbled by idees on tame elephants, whom the captives, curiously enough, do not touch. Single elephants are also noosed or decoyed by tame females; the pitfall method is too frequently fatal to be profitably employed if the elephants are wished alive. They are of course also hunted and killed both for sport and ivory. Sometimes, too, their ravages on cultivated ground have necessitated check. The shots are said to kill only on the forehead, temple, and behind the ear. The African elephant is not now trained, as it used to be, for war or show, but is rapidly being hunted to death to supply European markets with ivory. It is followed either on horse-back or foot, and some of the Arabs are said to be daring enough to face it with only sword and shield.

*Uses.*—The Indian elephant has been, and still is, much used as a beast of burden. In its half-domesticated state it becomes a patient and effective worker. They are of great service in lifting and carrying heavy burdens, which they edge on to their trunks with the trunk. An ordinary elephant can carry half a ton continuously on a level road. In their natural state they often march for 20 miles to their feeding-ground or water-supply. In captivity they require a great deal of care and as much food. 'A large tanker needs 800 lb. of green fodder in 18 hours.' Their expensiveness, delicacy, and infertility are obstacles to domestication. The African elephant, once trained for war and pageantry, is no longer tamed, apparently from lack of enterprise. The natives of Africa eat the flesh, and are said to be especially fond of the trunk, feet, and fat of the elephant. The skin is used for water-bags.

From very ancient times elephants have been used in war. Alexander encountered them in his campaigns; Semiramis took clever advantage of their prestige by making sham ones. In the Carthaginian wars, the Romans were at first disastrously affrighted by them, but with familiarity learned to terrify them with torches. They captured several from Pyrrhus in 276 B.C., and took them to Rome, calling them 'Lucanian oxen.' The Carthaginians are said to have used 140 elephants at the siege of Palermo; Hannibal took 37 over the Alps, where, according to Philonem Holland's quaint translation of Livy, they had 'much ado not to topple on their noses in the slabby snow-broth;' and the Romans themselves learned to use them. Even in modern times, in the East, they have continued to be so used, and in the Burmese war, though not actively engaged, elephants were found of great use both for transport and for clearing passages in the jungles.

Elephants have been almost equally used in pageantry and games. Cæsar held elephant tournaments and employed them to draw chariots, while Nero characteristically matched an elephant against a single fencer. So too they have for many centuries held their place in the Juggernaut processions, and were remarkably displayed in honour of the visit of the Prince of Wales to India.

*Ivory.*—The tusks of an elephant may weigh

150-300 lb., and 'a famous task exhibited by Grote & Co., New York, measures 8 feet 11 inches on outside curve, has a diameter at the base of 6½ inches, and weighs 184 lb.' They have small 'milk' predecessors, but these fall out when the animal is very young. The true tusks are what are called rootless teeth, growing from persistent pulp, and owe their value to the large mass, elastic nature, and somewhat peculiar texture of the dentine portion (see TOOTH). The enamel is very slightly developed, and only at the apex. It is estimated that about 75,000 animals, especially in Africa, have recently been killed annually for the sake of their tusks, while 500 tons per annum were imported into Great Britain alone between 1880-84. In more recent years the importation has decreased, there is no doubt that the ivory king is becoming rarer, and an abstinence from the purchase of ivory is the bounden duty of every admirer of the elephant. The fit use of this beautiful animal product is for works of high art, like those of the ancients, and not for handles of pocket-knives. For technical details, see IVORY.

*Proboscidean Fictions.*—Under this title, Holder, in his interesting account of the 'Ivory King,' collects a number of the oddities erroneously recorded in regard to elephants. Thus it was long believed that they shed their tusks every ten years, but buyers of ivory can no longer have such comfortable assurance. Writers of the 14th century allude to the belief that they have two hearts, such extremes of temperament do they exhibit! From the low position of the knee-joint, the idea arose that the elephant's legs bend in opposite directions to those of other animals; while a different view is expressed by Ulysses in *Troilus and Cressida*: 'The elephant hath joints, but none for courtesy, his legs are for necessity, not for flexure.' Choicest by far, however, is the expression to a common belief given by Sir Thomas Browne in *Pseudodoxia Epidemica*—the elephant 'hath no joints, and being unable to lye down, it lieth against a tree, which the hunters observing do saw almost around, whereon the beast relying by the fall of the tree falls also downo itselfe, and is able to rise no more.'

See DINOTHERIUM, IVORY, MAMMOTH, MASTODON; C. F. Holder, *The Ivory King* (London, 1886), an admirable account of the general natural history of the elephant, from which many of the above facts are derived; G. J. Romanes, *Animal Intelligence* (Inter. Sc. Series), and other works. For anatomical characters, see Huxley's *Anatomy of Vertebrates*, and Flower's *Osteology of the Mammalia*.

**Elephanta** (nativo *Gharāpurī*), an island over 4 miles in circuit, in the harbor of Bombay, 6 miles E. of the city, and 4 miles from the mainland. It owed its European name to a large figure of an elephant which stood near its former landing-place, but which, after 1814, gradually sank into a shapeless mass. Of the island's far-famed Brahmanic rock-caves, four are complete, or nearly so; the most important is the Great Temple, still used by the Hindus on Sivaite festivals. It is entirely hewn out of a hard trap-rock, and measures 130 feet from north to south, and the same distance from east to west; the body of the cave forms a square of about 91 feet, originally supported by twenty-six columns, and sixteen half-columns, of from 15 to 17 feet, many of which have been injured or destroyed. The most striking of its many sculptures is a three-headed bust of Siva,

nearly 18 feet high and 23 feet round the eyes. This unique bust, like most of the other figures here, has been much defaced, and policemen are now employed to protect the cave. The caves

Caves of Elephanta—Entrance.

most probably date from the 9th century. See Burgess, *The Rock Temples of Elephanta* (Bombay, 1871), and Fergusson and Burgess, *The Cave Temples of India* (1880).

**Elephantiasis Arabum** (also called *Cochin* or *Barbadoes Leg*, or *Pachydermia*) is a disease chiefly of tropical climates, and especially frequent in India. It consists in an overgrowth of the skin and connective tissue of the parts affected, with occasional attacks of inflammation resembling erysipelas. It is associated with, and probably caused by, obstruction of the lymphatic vessels of the affected part. In many cases occurring in the tropics, a parasitic worm (*Filaria sanguinis hominis*; see PARASITES) is found in the patient's blood, and is believed to be the cause of the obstruction; but the disease may occur from other causes. The lower limbs and genital organs are the parts usually affected, and may attain an enormous size; the scrotum has been known to weigh over 100 lb. In the early stages it can sometimes be reduced or kept in check by firm bandaging, with careful avoidance of all causes of irritation—e.g. over-fatigue, great changes of temperature. But in severe cases, amputation of the part affected is often necessary to allow the patient to move about at all. For the wholly distinct disease, *Elephantiasis Græcorum*, see LEPROSY.

**Elephantiné** (Arab. *Gezirat Aswadn*, or *Gezirat-az-Zahr*, 'isle of flowers'), a small island of the Nile, 'a mosaic of vivid green, golden sand, and black syenite,' lying opposite to Assouan (q.v.), the ancient Syene, on the confines of Egypt and Nubia, in 24° 5' N. lat., and 32° 34' E. long. The ruins of the ancient city are traced in a large mound near the modern villages. From this island the Greek mercenaries were sent into Ethiopia by Psammethichus I. to recall the Egyptian deserts, and it was garrisoned in the times of the Pharaohs, Persians, and Romans. The island was anciently called *Ab*, or the 'ivory island,' from its having been the entrepôt of the trade in that precious material. The most important ruins, preserved till 1822, when they were mainly demolished to build a vandal governor's palace, were a late granite gateway of the time of Alexander III.; and a small temple dedicated to Khnum, the god of the country, and Sati, the goddess of the inundation, which was

built by Thothmes III. and his successors down to Amenhotep III. Another remarkable edifice (also destroyed in 1822) was the Roman Nilometer, mentioned by Strabo, which appears to have been built in the time of the Cæsars; several inscriptions still preserved record the heights of inundation from the time of Augustus to Severus. The island had the honour of giving a dynasty (the 5th) to Egypt, and was the capital of the first nome of the Southern Kingdom; the inscriptions on the rocks attest the adoration paid by Seti I., Psammetichus II., and other monarchs, to the local deities. Other interesting monuments have been found on this island; amongst which may be cited part of a calendar recording an important chronological datum—the date of the rising of the star Sothis, marking the beginning of the Egyptian year, in the reign of Thothmes III. (1445 B.C.); a Roman quay; and numerous inscribed potsherds—principally receipts in the Greek language—given by the farmers of the taxes in the reign of the Antonines. The population of the island is at present exclusively Nubian.

See Wilkinson; Champollion; Mariette, *Mon. of Upper Egypt*; Brugnot, *Hist. of Egypt under the Pharaohs*; Birch, *Hist. of Anc. Pottery, Guide to First and Second Egyptian Rooms in the British Museum*; A. B. Edwards, *A Thousand Miles up the Nile*.

**Elephant-seal**, or SEA-ELEPHANT (*Macrorhinus proboscideus* or *leoninus*), the largest of the seals, the male measuring about 20 feet in length. It occurs in the southern oceans off Patagonia, Juan Fernandez, Kerguelen, &c. The colour is grayish, the teeth relatively very small, the hind-feet without nails. The males are much larger than the

Elephant-seal (*Macrorhinus proboscideus*).

females, and have a tubular prolongation of the snout, dilatable in excitement. They live in families and societies, and feed on fish and molluscs, especially cuttle-fishes. The skin furnishes leather; the oil is valuable for burning; and the tongue alone is palatable. Some distinguish a second, almost exterminated, species (*M. angustirostris*), found off the coasts of California and Western Mexico. See SEAL.

**Elephant's Foot**, or HOTTENTOT'S BREAD (*Tamus* or *Tesudinaria elephantipes*), a plant of the yam order (Dioscoreaceæ), of which the root-stock forms a large fleshy mass, curiously truncate, or somewhat resembling an elephant's foot, and covered with a soft, corky, rough, and cracked bark, recalling the shell of a tortoise, whence its other name. From this springs annually a climbing stem, which bears the leaves and flowers. The starchy root-stock is used as food by the Hottentots. The plant is not infrequent in hothouses. A few species are North American.

**Elephant-shrew**, a name applied to a number of long-nosed, long-legged insectivora, forming the family Macroscelidæ. They are natives of

Africa, and are notable for their agile jumping over loose sand. They use their hind-legs somewhat in kangaroo fashion. There are two genera, Macroscelides and Rhynchocyon, with fourteen species.

**Elettaria**. See CARDAMOMS.

**Eletz**. See JELETZ.

**Eleusine**, a genus of Grasses, of which several species are of importance as cultivated cereals, notably *E. corocana* and *E. indica* in India, and *E. Tucuuso* in Abyssinia. *E. indica* is now common in the United States.

**Eleusis**, next to Athens the most important town of ancient Attica, on the Bay of Eleusis, opposite Salamis, was connected with the capital by the Sacred Road. It was famous as the chief seat of the worship of Ceres, whose mystic rites were here performed with great pomp and solemnity from the earliest authentic times till the era of Alaric, by whom the second and famous temple of the goddess, designed by Ictinus, the architect of the Parthenon, was destroyed. For the Eleusinian mysteries, see MYSTERIES. The site of the old Eleusis is now occupied by the little village of Lefina, 16½ miles WNW. of Athens by rail.

**Eleuthera**, one of the Bahamas (q.v.), has an area of 238 sq. m., and a pop. of 7010.

**Eleuthera Bark**, an old name of Cascarilla Bark, borrowed from its native island. See CASCARILLA, CROTON.

**Elevation**, in Architectural Drawing, is a representation of the flat side of a building, drawn with mathematical accuracy, but without any attention to effect. For elevation in geology, see UPHOVAL; for elevation crater, VOLCANO.

**Elevation**, in Astronomy and Geography, means generally the height above the horizon of an object on the sphere, measured by the arc of a vertical circle through it and the zenith. Thus, the elevation of the equator is the arc of a meridian intercepted between the equator and the horizon of the place. The elevation of the pole is the complement of that of the equator, and is always equal to the latitude of the place. The elevation of a star, or any other point, is similarly its height above the horizon, and is a maximum when the star is on the meridian.

**Elevation of the Host**. See HOST.

**Elevators** (GRAIN) is the name given, especially in the United States, to erections for the transshipment of grain, and in which it is often stored for months, being weighed both when received and when sent out. There are elevators capable of storing 1,000,000 to 1,500,000 bushels of corn within their walls of wood. The largest are erected at Chicago and Buffalo. The grain on being received at the elevator is examined and graded, all of the same quality being kept together. The farmer or merchant who brings it receives an acknowledgment for so much grain of such a quality; and the grain which is delivered from the elevator on his account is grain of that quality, and not the same as he brought. In New York, floating elevators are frequently employed to transfer the grain from barges to sea-going vessels direct. Fixed elevators are generally built so as to be approachable by vessels on one or two sides, and have tramways running in on the level of the street; the chain of buckets which raises the grain moves, as the case may be, in an inclined plane passing through the wall to a vessel outside, or in a vertical plane into pits into which the grain has been shot from railway-trucks. The chain receives its motion from an endless band passing over one or two horizontal shafts in the upper part of the structure, the engine and boiler being

located in a building outside the elevator itself.—Elevators in hotels, &c. are in Britain generally called Lifts (q.v.).

**ELC.** See FAIRIES.

**Elf-bolts**, also called *Elfin-arrows*, *Elf-darts*, *Elf-shot*, and *Elf-stones*, names popularly given in the British Islands to the arrow-heads of flint which were in use among the early inhabitants of Britain and of Europe generally (see FLINT IMPLEMENTS). It was believed that elves or invisible beings shot these barbs of flint at cattle, and occasionally even at men. Thus, Robert Gordon of Straloch, an accomplished country gentleman of the north of Scotland, writing in 1654, tells how one of his friends, travelling on horseback, found an elf-bolt in the top of his boot, and how a gentlewoman of his acquaintance, when out riding, discovered one in the breast of her habit. Cattle dying suddenly in the fields were believed to have been struck by elf-arrows—a belief which yet lingers in Ireland. The elf-bolt was occasionally set in silver, so as to be worn on the person as a talisman, or had a hole drilled through it, so that it might be dipped in water, which, being thus endowed with healing virtue, was used sometimes as a wash, more commonly as a draught. As a talisman, the elf-bolt was believed to be most efficacious as a preservative from poison and witchcraft.

**Elgin**, the county town of Elginshire, 5 miles by rail SSW. of its seaport, Lossiemouth, 37 ENE. of Inverness, and 178 N. of Edinburgh. It lies on the Lossie in the 'garden of Scotland'; and while it retains a few quaint old houses, a cross (restored in 1838), and its ruined cathedral, it has brightened up much during the 19th century. The Elgin Institution was erected in 1832 as an almshouse and school, out of £70,000 bequeathed by Andrew Anderson (1746-1822), who from private had risen to be major-general in the service of the East India Company. Other edifices are Gray's Hospital (1819) and the adjoining asylum (1834-35), the county buildings (1806), the court house (1841), the market buildings (1850), the academy (1800), and the parish church (1828), with a tower 112 feet high. The once glorious Gothic cathedral (1224-1538) was a cruciform structure, 289 feet long by 120 across the transept, with two western towers, and a loftier central spire (108 feet). It was partially burned in 1270, and again in 1390 by the 'Wolf of Badenoch'; was dismantled in 1568; and in 1711 was finally reduced to ruins by the fall of the great tower. The chapter-house, with its 'prentice pillar,' is noteworthy. The town itself has suffered much from fire, its partial destruction in 1452 at the hands of the Earl of Huntly giving rise to the proverb 'Half done, as Elgin was burnt.' Little remains of the royal castle, which in 1296 lodged Edward I. of England; its ruins are surmounted by a monument (1839-55) to the last Duke of Gordon. A royal burgh since the reign of David I. (1124-53), Elgin unites with Banff, Macduff, Peterhead, Inverurie, Cullen, and Kintore to return one member to parliament. Pop. (1831) 4493; (1891) 7799. See *Young's Annals of Elgin* (1879).

**Elgin**, a city of Illinois, on the Fox River, 36 miles WNW. of Chicago by rail, with large watchworks employing 500 hands, and manufactures of carriages and agricultural machinery. Pop. (1890) 17,429.

**Elgin and Kincardine**, EARL OF, Governor-general of India. James Bruce, eighth Earl of Elgin, and first Baron Elgin in the peerage of the United Kingdom (1819), was born in London, 20th July 1811. He was son of the seventh Earl of Elgin (1766-1841) who brought from Athens the collection of sculptures known as the 'Elgin Marbles.' As governor of Jamaica (1842-46), and as governor-general of Canada (1847-54), he displayed administrative abilities of the highest order. While on his way to China in 1857, as plenipotentiary extraordinary, he learned at Singapore the outbreak of the Indian mutiny, and promptly diverted the Chinese expedition to the aid of Lord Canning. The mission to China was delayed, but ultimately, after some military operations and diplomacy, issued in the treaty of Tientsin (1858). He also negotiated a treaty with Japan, by which certain ports were opened to British trade. On his return home he was appointed Postmaster-general. In 1860 he was again in China for the purpose of enforcing the ratification of the treaty. A combined English and French force penetrated to the capital, and enabled Lord Elgin and Baron Gros to dictate a peace under the walls of Peking. On the expiration of Viscount Canning's term of service, the governor-generalship of India was offered by Lord Palmerston to Lord Elgin (1861), and accepted by him. He died at Dharmasala in the Punjab, 20th November 1863. See Walrond, *Letters and Journals of Lord Elgin* (1872); and Lawrence Oliphant, *Mission of Earl of Elgin to China* (1859).

**Elgin Marbles**, a celebrated collection of ancient sculptures, brought from Greece by the seventh Earl of Elgin, then ambassador to the Porte, and acquired from him by the nation for the British Museum in 1816, at the sum of £35,000. Early in the century he obtained a firman to examine, measure, and remove certain stones with inscriptions from the Acropolis at Athens, then a Turkish fortress. His agents, on the strength of this firman, removed the so-called Elgin Marbles, packed before Elgin's recall in 1803, but not finally conveyed to England till 1812. They are said to have cost the ambassador upwards of £74,000; and

Part of the Frieze of the Parthenon—Elgin Marbles.

both before the purchase by the government and afterwards, there was fierce controversy as to the artistic value of the statues, and Elgin's right to remove them from Athens. Lord Byron's view as to the unjustifiableness of the removal was shared by

many, who nevertheless believed not merely that the marbles were thus saved from great risks, but that they were now made vastly more accessible to students than they could have been in Athens during the troublous times that followed.

These sculptures adorned certain buildings on the Acropolis of Athens. The chief portions, which are from the Parthenon or Temple of Minerva, were designed by Phidias, and executed by him, or under his superintendence. They consist mainly of statues from the pediments, metopes, and a large part of the frieze of the cella (see *ATHENS*, Vol. I., p. 538): a figure from the Erechtheum, and a statue of Dionysus, and part of the frieze of the Temple of Winged Victory. See Newton in the *Contents of the British Museum, Elgin Room* (1881-82).

**Elginshire**, or **MORAY**, a Scottish county extending 30 miles along the low shore of the Moray Firth. It is 34 miles long, and 483 sq. m. in area, a former detached portion having in 1870 been annexed to Inverness-shire, whilst a corresponding portion was transferred from that county to Elginshire. The surface has a general southward ascent, and attains a maximum altitude of 2323 feet. Rivers are the Spey, Lossie, and Findhorn; and of several small lakes much the largest is Lochindorb (2 miles by 5 furlongs). West of the Findhorn's mouth are the sand-dunes of Culbin, due to drifting chiefly in 1694, and some of them rising 118 feet (see *DRIFT*). The predominant rocks are crystalline in the south; next Old Red Sandstone, with fish remains; and then reptiliferous sandstone of (probably) Triassic age (see *DICYNODON*). Agriculture is highly advanced over all the flat fertile lower tract; still, only thirty-one per cent. of the entire area is in cultivation. Burghhead and Lossiemouth are fishing-villages; and whisky is distilled in the higher districts. Elgin and Nairn shires return one member to parliament. Pop. (1801) 27,760; (1841) 35,012; (1891) 43,488. The ancient province of Moray included the counties of Elgin and Nairn, with parts of Banff and Inverness shires. Scandinavians early gained a footing; and it did not become an integral part of the Scottish kingdom till the latter half of the 12th century. Antiquities, other than the pseudo-Roman remains of Burghead (Ptolemy's *Alata Castra*), are Kinloss Abbey (1150), Plusecarden Priory (1230), a Romanesque church at Birnie, and the castles of Duffus, Lochindorb, and Spynie, the last with memories of Bothwell. See Shaw's *History of Moray* (1775; 3d. ed. 1882).

**Eli**, high-priest at Shiloh, before whom the child Samuel ministered unto the Lord (1 Sam. i.-iv.). He also judged Israel for forty years (according to the Hebrew text; the Septuagint has twenty years); and in his old age had to bear the curse that followed his culpable negligence in not restraining the evil dispositions of his sons Hophni and Phinehas. He fell from his seat and died on hearing that the ark of Jehovah had been taken by the Philistines.

**Elias Levita**. See *LEVITA*.

**Elic**, a pretty little watering-place of Fife, 23 miles NE. of Edinburgh (by rail 34). Pop. 917.

**Élie de Beaumont**. See *BEAUMONT*.

**Elijah** (in the New Testament, *Elias*), the greatest of the prophets of Israel, flourished about 900 B.C., during the reigns of Ahab and Ahaziah. For the story of his life a reference to the Old Testament is sufficient (1 Kings, xvii.-xix., xxi.; 2 Kings, i., ii.; 2 Chron. xxi. 12-15). The anticipation of his return as the precursor of the Messiah harmonises with the account of his removal from the earth, and finds support in the words of the last prophet (Mal. iv. 5). In the New Testament this prophecy is declared to have its fulfilment in John the Baptist, who is said to have come 'in the spirit

and power of Elias' (Matt. xi. 14; xvii. 11-13; Mark, ix. 13; Luke, i. 17). Elijah appears with Moses on the Mount of Transfiguration. In Russian folklore, the ideas that once were associated with Perun, the thunder-god, have become attached to the Prophet Ilya or Elijah, on whose festival (20th July) a beast is sacrificed in many districts. See *Elijah, his Life and Times*, by Dr Milligan (1887); and *The Hallowing of Criticism: Nine Sermons on Elijah*, by T. K. Cheyne (1888).

**Elimination**, in Algebra, is the operation which consists in getting rid of a quantity or letter which is common, say, to two equations, by forming out of the two a new equation, in such a way as to make the quantity in question disappear. In complicated equations, elimination becomes difficult, and often impossible. Elimination is an important process in other sorts of reasoning besides the mathematical; in this larger acceptation, it means the setting aside of all extraneous considerations -- of everything not essential to the result. In astronomical observations, the elimination of errors of observation is often effected by repeating the observations several times in such a way as to cause the errors to be of opposite kinds, then adding the observed values, and taking their average. -- The word to 'eliminate' is often erroneously used in the sense of to 'elicit,' or bring to light.

**Eliot**, CHARLES WILLIAM, president of Harvard University, was born in Boston in 1834, and was educated at Harvard, where he filled some minor posts, and became president in 1869. Under his rule the university has been doubled in strength, and the old prescribed curriculum has been finally abandoned for an optional system of studies. President Eliot is LL.D. of Williams, Princeton, and Yale, and has published, with Professor Storer, two manuals of chemistry.

**Eliot**, GEORGE. This is the *nom de plume* of the great English novelist, who is perhaps best known as the author of *Adam Bede*. She was born on 22d November (St Cecilia's Day) 1819, and died on 22d December 1880. Her baptismal name was Mary Ann Evans, but she usually signed herself Marian Evans. She was the youngest daughter of the second family of Mr Robert Evans, a land-agent in Warwickshire, on the property of Mr Francis Newdigate. Mr Evans was at the time of the child's birth living at Ailbury Farm, on the Newdigate property. Four months later he removed to Griff on the same property, 'a charming red-brick, ivy-covered house,' and here the afterwards celebrated authoress lived during the first twenty-one years of her life. Robert Evans was a man of strongly-marked and strenuous character, many of the leading traits of which were transferred by his daughter to the characters of Adam Bede in the novel of the same name, and of Caleb Garth in *Middlemarch*. But as Mr Evans died in 1849, and George Eliot's first work of fiction was produced in January 1857, the father was never made aware of the character of the daughter's genius. Of the life at Griff, many of the features are given in the sketch of Maggie Tulliver's and Tom's childhood in the *Mill on the Floss*; and especially her relation to her own brother Isaac, who was her senior by three years, is there powerfully painted. Her first school was at Miss Lathom's of Attleboro, where she remained between the ages of five and nine. Then she went to Miss Wallington's at Nuneaton, where the principal governess was Miss Lewis, with whom she formed a close friendship, and with whom she corresponded during those earlier years of expanding mind and receding faith, which intervened between her father's removal to Coventry in 1841 and his death in 1849. Between the ages of thirteen and

sixteen, she went to school at Miss Franklin's at Coventry, where she became for a time a fervent evangelical. She lost her mother, whom she loved devotedly, in 1836, when she was only sixteen; and early in 1837 her elder sister Christiana, who was five years her senior, and whose character and relation to herself are said to have been in some degree reflected in the Celia of *Middlemarch*, and in the relation between Celia and Dorothea in that tale, married Mr Edward Clarke, a surgeon, practising at Meriden in Warwickshire. From this time Mary Ann Evans took entire charge of her father's house. A master came over from Coventry to give her lessons in German and Italian, and another came to teach her music, of which she was passionately fond throughout life. But besides her studies in language and music, she was an immense reader on all sorts of subjects which interested her.

In the spring of 1841, when Mary Ann Evans, or Marian Evans, as she now called herself, was just of age, her brother Isaac married and took the house at Griff, her father removing to Foleshill Road, in the outskirts of Coventry. Here she became acquainted with Mr Charles Bray, the author of several works setting forth the philosophy of necessity from the phrenological point of view, and formed a close friendship with his wife (*née* Caroline Hennell), as well as with her sister Sarah, and with her brother Charles Hennell, who had published in 1838 *An Inquiry concerning the Origin of Christianity*, from the rationalistic point of view. On 2d November 1841, Marian Evans announces to Miss Lewis, her evangelical friend, that she is about, as she hopes, 'to effect a breach in the thick wall of indifference, behind which the denizens of Coventry seem inclined to intrinse themselves,' and her biographer, Mr John Cross (to whom she was married in 1880), says that 'this probably refers to the first visit paid by Miss Evans to Mr and Mrs Bray at their house in Coventry.' We understand it as anticipating some success in bringing her new friends to a more religious state of mind. If so, the result was just the opposite of her expectations. Before a fortnight had passed—i.e. on the 11th November, she writes to the same friend anticipating that Miss Lewis may feel estranged from her as a consequence of some revolution which was taking place in her own mind, and that the visit which Miss Lewis was to have paid to Miss Evans at Christmas may no longer be one which she would wish to pay; and before the end of the year she had so greatly offended her father by refusing to go to church that he actually formed some intention, though he did not carry it out, of breaking up his household and going to live with his married daughter. Subsequently Marian Evans withdrew her objection to going to church, though she did not modify her views, and the breach between father and daughter was avoided.

At the opening of 1844, the work of translating Strauss's *Leben Jesu*, which had been at first undertaken by Mrs Charles Hennell, was transferred to Marian Evans, and at this she worked most laboriously till its publication in 1845. It was done in very scholarlike fashion. Indeed, the accuracy of George Eliot's work, whenever scholarship was needed, was all the more remarkable for her great imaginative power. There was nothing loose or slipped about her. She may occasionally be fairly accused of pedantry, never of slovenliness, never of carelessness concerning facts, or of trusting to her imagination for what she had the means of verifying. She was painstaking by temperament as well as by self-discipline, though it would be difficult to find a case in which that very bad definition of genius, as 'an infinite

capacity for taking pains,' would be more wholly inapplicable. George Eliot had a vast capacity for taking pains, and she had also a great genius; but her capacity for taking pains was as distinct from her genius, and showed itself in intellectual achievements as different as *Silas Marner* from her translation of Strauss's *Leben Jesu*. She translated later Spinoza's *Tractatus Theologico-Politicus*, and in after-years his *Ethics*, though we are not aware whether either translation was ever published, certainly not with her name. On the last day of May in 1849 her father died, and on the 11th June Marian Evans went abroad with Mr and Mrs Bray, ultimately to Geneva, where she remained for some months, the Brays returning home without her. Towards the close of March 1850 she returned to England, crossing the Jura on a sledge, and reaching London on 23d March. She now began to write for the *Westminster Review*, and in September 1851, in the year of the Great Exhibition, she became its assistant editor, lodging at its headquarters in the Strand, and becoming the centre of the literary circle of which Mr Herbert Spencer and Mr G. H. Lewes were two of the most influential members. It was at this time that she translated Feuerbach's *Essence of Christianity*, the only book to which she appended her real name. The drift of this book was to show that God is only a 'virtual' image of man, the magnified form of his hopes and desires.

Gradually her intimacy with Mr Lewes grew, and in 1854 she formed a connection with him which lasted till his death in 1878, a connection which was the great false step of her life. In July 1854 she went abroad with him, staying three months at Weimar, where he was preparing for his *Life of Goethe*. After a somewhat longer stay at Berlin, George Eliot and Mr Lewes returned to England, and took up their abode first at Dover, then at East Sheen, and then at Richmond. In November 1856, when she was just thirty-seven, she attempted her first story, *The Sad Fortunes of the Rev. Amos Barton*, the commencement of the *Scenes of Clerical Life*. The first part of it was published in *Blackwood's Magazine* in January 1857, and almost all who read it recognised at once that a new English author of great power had arisen. This story was quickly followed by *Mr Gilfil's Love Story* and *Janet's Repentance*. In 1858 she wrote *Adam Bede*, partly at home, partly abroad at Munich and Dresden, completing it at Richmond in November. After the publication of this brilliant story, which had the most marvellous success, George Eliot found to her amazement and annoyance that a Mr Liggins, who had lived in the same country as herself in the Midlands, claimed to be himself the author. There was a sharp controversy in the *Times* on the subject, and it was not till the publisher, Mr Blackwood, had intervened, that Mr Liggins's authorship was generally discredited. After the publication of *Adam Bede*, *The Mill on the Floss*, *Silas Marner*, *Romola*, and *Felix Holt* appeared in succession, but not rapid succession, for George Eliot always took her time, the last story coming out in 1866. Her first poem, *The Spanish Gypsy*, was published in 1868, followed in the next year by *Agatha*, *The Legend of Jubal*, and *Armstrong*; and in 1871 appeared the first part of what proved to be, we think, in every sense her greatest work, *Middlemarch*. After that *Daniel Deronda*, published in 1876, showed a marked falling off in power, though many of the scenes are sufficiently rich in pathos, humour, and insight. Of the *Impressions of Theophrastus Such*, a volume of somewhat miscellaneous essays not unlike Thackeray's *Roundabout Papers* in their rather

vague structure, no good critic, we think, formed any very high estimate.

After the death of Mr Lewes, on 28th November 1878, George Eliot, who was always exceedingly dependent on some one person for affection and support, fell into a very melancholy state, from which she was roused by the solicitous kindness and attention of Mr John Cross, an old friend of her own and of Mr Lewes's, and to him she was married on 6th May 1880. Their married life lasted but a few months. George Eliot died in Cheyne Walk, Chelsea, on 22d December of the same year, and is buried in Highgate Cemetery, in the grave next to that of Mr Lewes.

As a novelist, George Eliot will probably always stand among the greatest of the English school; above Richardson, whom she greatly admired, and with whose painstaking and elaborate style of portraiture she had something in common, though in her preference for studies taken from simple rural life, from commonplace subjects so delineated as to bring out the humorous side of human shortcomings and the overmastering power of pitiable passions, she approached nearer to the still greater genius of Fielding. But her mind had not the movement and vivacity of Fielding's. If it had had that movement, that elasticity, that freedom of life in it, her genius would probably have shown itself much earlier than it did, and not waited till she was close upon forty before it betrayed even its existence. In early life she seems to have given her whole mind to the higher problems of life, and to have declared them virtually insoluble before she took refuge in portraiture, with the wonderful power she actually displayed, the disappointments, the breakdowns, the narrow discontents, as well as the generous hopes and unsatisfied ideals of other human beings. She did not give the first-fruits of her intellectual energy to fiction. She exhausted, to her own thinking, the province of theology first, and having accepted with her usual too great docility the negative view of those who held that we have no trustworthy evidence that Christ's life was a revelation of divine power at all, and who held that Christianity is a mere dream dreamt in the idealising mood of eager human aspiration, she passed on sadly to a pitying study of man in the frame of mind of one who is determined to make the best of a bad business. And she extracted, perhaps, from our human lot all the good that it is possible for any one to extract from it who has once come deliberately to the conclusion that, though something may be done to elevate, and a good deal to alleviate it, and though not a little amusement may be extracted from it, yet that no power can really transfigure it, and that the more modest the aim, the less serious will be the inevitable disappointment. This subdued tone of regret that the highest human endeavour is destined to be baffled runs through all her tales, and it can hardly be doubted that their pervading melancholy is at least in some degree due to the false step which she herself, under the influence of a negative school of religious thought, had deliberately taken, when she sacrificed her own life to the ends of a connection out of which most of the joy, and almost all the sacredness, were taken by the unnatural and morally humiliating circumstances under which she entered upon it. It was greatly to her credit that, in spite of these circumstances, she steadily refused to lower the moral ideal at which she aimed, though she pursued it with scanty hope, and without the assistance of the faintest trust in the help of any higher power. She told her friend Miss Hennell in 1857, when the success of her *Scenes of Clerical Life* was already assured: 'If I live five years longer,

the positive result of my existence on the side of truth and goodness will outweigh the small negative good that would have consisted in my not doing anything to shock others, and I can conceive no consequences that will make me repent the past' (*Life and Letters*, vol. i. p. 461). She lived twenty-three years more; but the good of living up to one's own ideal is neither small nor negative, and the *Life* appears to show that the shock of having herself contributed to the world an example of a mode of life of which in her literary work she was constantly struggling to 'outweigh' the influence, was far greater and more enduring than she had at this time realised.

George Eliot's mind was one of extraordinary reflective power, but deficient in vivid personal instincts. She notices in *Silas Marner* how slowly impressions grow up within us, and how little we are sometimes aware of the origin of even those impressions which are destined to produce the greatest effects upon our character and external life. 'Our consciousness,' she says, 'rarely registers the beginning of a growth within us any more than without us. There have been many circulations of the sap before we detect the smallest sign of the bud.' In most men and women, such obliviousness of the first appearance of a germ of evil would hardly apply to a violation of wholesome instincts of that peculiar and marked kind by which she set her actual life at variance with her moral ideal. But perhaps it was so in her case. Her *Life and Letters* appear to show that the suave and long-drawn melancholy and somewhat artificial condition of self-repression in which she lived grew upon her more and more as 'the sap circulated' and fed her ideal of the true relation of husband and wife. In story after story she attempted to impress upon others the absolute sacredness of the relations to which her own action had apparently shown her to be indifferent. Her most impressive stories, *Adam Bede*, *Silas Marner*, *Romola*, *Felix Holt*, *Middlemarch*, and *Daniel Deronda*, were all penetrated with the desire to show how selfish and desecrating what is called love may be without marriage, and how equally selfish and desecrating marriage may be without love; yet at every return to that subject there seems to be less of hopefulness, less of awe, less of testimony to the sharp remorse which follows wrong-doing, less of vivid instinct, more of the tone of tragic warning, more of a tendency to acquiescence in inevitable misery, in her treatment of the theme.

Her pictures of the English farmers and tradesmen and the lower middle class generally of the Midland counties are hardly surpassed in English literature, and may be put on a level with Sir Walter Scott's similar pictures of the Scotch peasantry. Jennie and Effie Deans in the *Heart of Midlothian* are hardly more impressive than Dinah and Hetty in *Adam Bede*, and many might plausibly contend that they are less so. George Eliot's drawing had finer touches, and was more from within; Sir Walter Scott's was more rapid and vigorous, and excited a deeper interest in the outward careers of his *dramatis personæ*. Then again, George Eliot's farmers and millers, and farriers and auctioneers, and parish-clerks, are painted not with more humour perhaps, but with humour of a rarer and finer kind, though it is less popular and effective than Sir Walter Scott's ballies and drovers, and dominies and gypsies. What George Eliot is too frequently deficient in is action; what Sir Walter lacks is depth of insight. But on the whole George Eliot's stories give us at least as good a picture of the life of the Midland counties, as masterly and full-length portraits of the slow-moving, beef-consuming, habit-ridden population of those counties in the earlier part of this

century, as Sir Walter Scott has given us of the Border counties during the whole of the 18th century, with their wilder and more adventurous people. Of course there is a great difference in method between the two novelists, corresponding pretty closely to the difference between their favourite subjects. Sir Walter loved to show his favourites embarked in perilous adventures, Rob Roy gaining access to the Glasgow Tolbooth, and endangering his own neck to help a friend, or again, persuading the soldier to whom he was buckled to let him loose himself and dive for his life as they crossed the Forth. George Eliot on the other hand is seldom so successful as when she patiently develops her characters in rather slow but humorous dialogue—such dialogue as Shakespeare loved to interpolate in his plays when he chose to show us how the 'Goodman Dull' of the Midlands talked away in his stupid but comfortable self-satisfaction. Perhaps now and then George Eliot a little overlooks this microscopic view of inarticulate natures. In that curious short story of hers, *The Lifted Veil*, she gives a picture of a man with a quite preternatural insight into the vagrant and frivolous background of the minds of those amongst whom he lives, who is made to complain of 'the obtusion on my mind of the mental process going forward in first one person and then another, with whom I happened to be in contact; the vagrant, frivolous ideas and emotions of some uninteresting acquaintance . . . would force themselves on my consciousness like an importunate, ill-played musical instrument, or the loud activity of an imprisoned insect.' Ifad not George Eliot herself some curious gift of the same kind?—as for instance in the very long analysis she gives of the way in which the gossips of Raveloe constructed, out of their own consciousness, the dress and personal appearance of the pedlar who is supposed by them to have stolen Silas Marner's gold? She seems sometimes to have had the buzz of dull but excited gossip almost revealed to her by a kind of disagreeable intuition, and to have written it down at too great length in order to rid herself of its leaden predominance over her imagination.

But if in delineating character George Eliot is often more than the equal of Sir Walter Scott, because she goes deeper and has a more penetrating insight, she is greatly his inferior in play and richness of pictorial imagination, in rapidity of movement, and in warmth of colour. *Romola*, her one historical romance, though it is full of subtlety of conception, contains some very striking figures, and is painted with a surprising minuteness of realistic detail, is a doubtful success. Sir Walter Scott never failed in making the chief historical figure of his historical romances the most interesting figure in his group. His studies of Mary Stuart in the *Abbot*, of Elizabeth in *Kenilworth*, of James I. in the *Fortunes of Nigel*, and of Louis XI. in *Quentin Durward* are studies which will live in the imaginations of men as long as the most vivid of historical portraits. George Eliot did not thus succeed in painting Savonarola. It was in Tito and Tessa that she achieved her great successes. As regards the historical background of *Romola*, one can hardly say that it holds its place at all as compared with even the least successful historical romance of Sir Walter Scott, say, *Anne of Geierstein* or the *Fair Maid of Perth*. George Eliot's imagination was not buoyant enough to travel back into these far regions of history, and create them anew for us. Nor does her story move rapidly enough to make up for the difficulty of transporting our sympathies to so distant a region. We miss the vividness and we miss the action which are needful for the art of historical romance.

And again in her poetry George Eliot falls far

short of Sir Walter Scott; she is sombre, stately, even Miltonic after a fashion of her own, but Miltonic without Milton's felicity and charm. She is as grandioso as Milton without being as grand. Sometimes she attains true grandeur, as in her delineation of the selfishness that remained at the heart even of the inspired musician Jubal:

This little pulse of self that living glowed  
Through three three centuries, and divinely strowed  
The light of music through the vague of sound,  
Ached smallness, still in good that had no bound.

The last line is grand, but not with Milton's sweet and winning grandeur. And usually George Eliot falls quite short of true grandeur in her poetry, and seems to be impressive without actually impressing the reader. The rhythm is laboured, the thought is laboured, the feeling is laboured, and the effect is more artificial than artistic.

Perhaps the most curious feature of George Eliot's genius is that she wrote so very much better and with so much more ease when she was writing dramatically than she did when she was writing her own thoughts in her own name. There is hardly a good letter—considered as a letter—in the whole three volumes, made up chiefly out of her letters, which Mr Cross has given to the world. There is on the contrary hardly an ineffective speech put into the mouth of any of the characters whom she delineated in her novels. Sir Walter Scott has given us a far larger proportion of ineffectively painted characters, though also a greater number of effectively painted characters, than George Eliot. There is hardly a country squire, or dairymaid, or poacher, or innkeeper, or country lad or lass to whom George Eliot does not give a thoroughly individual voice; but when she comes to speak for herself, her voice is measured, artificial, monotonous, and a little over-sweet. Her letters read as if they were turned out by machinery, though machinery invented by some gently intellectual and laborious mind. Scott's letters are delightful reading; Miss Brontë's are full of interest; even Miss Austen's, though they disappointed everybody, give the impression of a lively and observant mind. But George Eliot's have no freedom or personal stamp upon them, unless the absence of personal feeling be itself a personal stamp. It almost seems as if her mind had been intended more as an instrument for interpreting the minds of others, more as a phonograph through the agency of which the natures of all the various interlocutors with whom she met could be delicately registered and made to report themselves to the world, than as a distinct organ of her own taste and purpose. George Eliot is in the highest degree original in her power of interpreting others, but she gives an effect of faded second-hand suavity when she comes to interpret herself. Nevertheless she will be named in the same category with Sir Walter Scott, Thackeray, and Dickens, perhaps even above Miss Austen, if only for the richness and quantity of her admirable work. When the novelists of the nineteenth century come to be discussed in the twentieth, she will certainly rank above Trollope, or Mrs Oliphant, or Miss Brontë, or Mrs Gaskell, or Bulwer Lytton, or any of the other clever novelists who have filled so large a part of this century with their lively and skilful work.

See the *Life of George Eliot*, as unfolded in her *Letters and Journals*, edited by J. W. Cross (3 vols. 1885-86); *George Eliot*, by Mathilde Blind (1888); F. W. H. Myers, *Essays: Modern* (1883); *Essays, Theological and Literary*, by R. H. Hutton (1871), and his *Modern Guides of English Thought* (1887).

**Eliot, JOHN**, 'the Indian Apostle,' was born probably at Wiford in Hertfordshire in 1604, the son of a yeoman, graduated at Cambridge in 1622, and, after taking orders in the Church of England,

quitted his native country for conscience' sake, and landed at Boston in New England in 1631. For some months he 'exercised' in the church there, but being fore-engaged to friends who had settled at Roxbury, he repaired thither in the summer of 1632. In 1646, after two years' study of the language, he delivered a long sermon in the native dialect at Nohantum, about five miles from Roxbury; and other meetings soon followed. He shortly after began to establish his converts in regular settlements, his work meeting with approval both in the colony and at home; in England a corporation was founded in 1649 'for the promoting and propagating the Gospel among the Indians of New England,' which defrayed the expenses of the preachers and the cost of printing translations. At one time there were over a dozen townships of 'praying Indians' within the bounds of Massachusetts, and many more outside these limits, with numbers estimated in 1674 at 3600; but, although the organisation survived until the death of the last native pastor in 1716, the decay of the 'praying towns' was rapid after the war with a native king, Philip (1675), in which the converts suffered equal cruelties at the hands of their countrymen and of the English, whom they are nevertheless believed to have saved from extinction. Eliot died at Roxbury, 21st May 1690; there are monuments to his memory in the Indian burying-ground at South Natick, and at Newton, near the scene of his first Indian sermon. A man of earnest piety and devotion to evangelisation, warm-hearted, and of a singularly attractive manner, he has left a memory that is honoured among the first in the history of New England. Along with his colleague Thomas Weld, and Richard Mather, Eliot prepared an English metrical version of the Psalms, the 'Bay Psalm-book' (Camb. 1640), which was the first book printed in New England. He was also the author, among other works, of *The Christian Commonwealth* (Lond. 1659; suppressed by the general court, and now extremely rare), of *The Communion of Churches* (Camb. 1665; the first book privately printed in America), of several tracts, and of translations into the Indian tongue of Baxter's *Call*, Bayly's *Practice of Piety* (abridged), and Shepard's *Sincere Convert*. But the great work and the noblest monument of his devoted life was the translation of the Bible into the tongue of the Indians of Massachusetts (Algonquin), of which the New Testament appeared in 1661, and the whole work, with a version of the Psalms in metre, and a page of 'catechism,' in 1663. His *Indian Grammar Begun* was printed in 1666, his *Indian Primer* in 1669; a reprint of the only known copy of the latter, now in the library of the Edinburgh University, was issued in 1880, along with a reprint of one of the only two extant copies (not alike) of *A Christian Covenanting Confession*. The finest collection of unique and scarce copies of Eliot's works is in the Lenox Library, New York; many of them have been reprinted.

The best life of Eliot is that by C. Francis in vol. v. of the first series of *Sparks's American Biography* (1836), the earliest that by Cotton Mather (1691); see also two careful articles in the *Cyclopedia of Amer. Biog.* (vol. ii. 1887) and the *Dict. of Nat. Biog.* (vol. xvii. 1889).

**Eliot, Sir John**, English statesman, the earnest champion of the supremacy of parliament in the government of the nation, was the son of a country gentleman of Cornwall, in which county, at Port Eliot on the Tamar, he was born, 20th April 1592. His education was that usual for young men of his position. During the course of his continental travels he became acquainted with Villiers, afterwards Duke of Buckingham, an acquaintance-ship which had a most important influence

upon his subsequent parliamentary career. In fact his relations with Buckingham, first in support of the duke, and afterwards in antagonism to him, and his position as an ardent champion of the independence of the House of Commons are the two chief determining factors of his public life. He entered the parliament of 1624 as an adherent of Buckingham, whom he heartily supported in his 'warlike policy against Spain. But during the course of the next parliament (1625) his eyes seem to have become opened to the true character and designs of the favourite, and he finally broke with him that same year, owing to an arrogant refusal on Buckingham's part to acknowledge the House of Commons as the real ruling power in the nation. And in Eliot's case, as in that of most enthusiastic impetuous natures, it was almost a matter of course that, having become convinced of the unworthiness of his former leader, he should swing over to the extreme of fierce, implacable hostility to him. Accordingly, in the next parliament, in which, from the force of circumstances, Eliot was the leading spirit, his policy was in the main one of antagonism to the king, and finally culminated in the impeachment of Buckingham. For this he was sent to the Tower on 11th May, and not released until the 19th. In the parliament of 1628 Eliot raised his voice against arbitrary taxation, and was instrumental in forcing from Charles the celebrated Petition of Right. For having again protested formally against the king's proceedings in matters of taxation and religion, Eliot was, on 4th March 1629, sent, along with eight other members, to the Tower; and steadfastly refusing to acknowledge himself to have been in error, was kept in confinement until his death, on 27th November 1632. During his incarceration, Eliot composed an account of Charles's first parliament, *Negotium Posterorum* (first printed in 1881); a philosophico-political treatise, *The Monarchy of Man* (1879); and *An Apology for Socrates* (1881), a vindication of his own public conduct. Besides these he also left *De Jure Majestatis, a Political Treatise of Government*, and the *Letter-book of Sir John Eliot*, both published in 1882. See the Biography by John Forster (2d ed. 1871).

**Eliot, Sir Thomas.** See ELYOT.

**Eliot, Samuel**, an American author, born in Boston in 1821, graduated at Harvard, and was professor of History and Political Science in Trinity College, Hartford, in 1856-64, being also its president in 1860-64. Between 1864 and 1874 he lectured there and at Harvard, and he afterwards filled important posts in the Boston schools. He received the degree of LL.D. from Columbia in 1863, and from Harvard in 1880. The first two parts of a *History of Liberty* appeared in 1847-49-53. He also published a *Manual of United States History* (1850; revised ed. 1873).

**Eliott, General.** See HEATHFIELD (LORD).

**Elis**, one of the ancient divisions of the Peloponnesus, bounded N. by Achaia, E. by Arcadia, and W. by the Ionian Sea. The northern and more fertile region, watered by the Peneüs and numerous smaller streams, was famed for the excellence of its horses; the southern and more rugged district is drained by the Alphæus, which rises in the mountains of Arcadia. On its banks were the grove and temple of Olympie Zeus, and the plain in which the great Olympie games were celebrated. For long the sacred character of Elis, as the seat of the greatest of the national festivals, protected the country from invasion, but during the Peloponnesian war, the Athenians, and afterwards the Spartans, disregarded the privileges of the Eleans. See OLYMPIA, for excavations.

**Elisha** (in the authorised version of the New Testament, *Eliseus*), a prophet of Israel, the successor of Elijah. He exercised his functions for a period of fifty-five years, during the reigns of Jehoram, Jehu, Jehonadab, and Jehoshaphat (1 Kings, xix. 19; 2 Kings, ii.-ix., xiii. 14-21). Though a double portion of Elijah's spirit was promised to him, he displays little of his master's impetuous and uncompromising temper. The contrasts between the two prophets have been frequently discussed. Elisha is canonised in the Greek Church; his day is the 14th of June.

**Elixir** (Arab. *el iksir*, 'the philosopher's stone,' see ALCHEMY), a term in pharmacy which has come down from the days of Alchemy (q.v.). By the alchemists the term was applied to various solutions employed in the attempt to transmute metals. But the most notable elixir, sought after by many, was the *elixir vite*, 'the elixir of life,' that sublime, potent, perfect, invaluable preparation which, if discovered, would confer immortality or at least extreme length of life on him who drank it. The name has recently been appropriated to a class of American pharmaceutical preparations. These are very different from the old-fashioned elixirs, which corresponded in the main to our modern tinctures; for in the American elixirs the first object sought is to present the medicine under an agreeable form, even if frequently with a loss of potency. These newer elixirs are often highly alcoholic, and are sweetened and flavoured with great skill. In British pharmacy, *Elixir of Vitriol* is almost the only representative of the old class, and is prepared by mixing together sulphuric acid, alcohol, tincture of ginger, and spirit of cinnamon. This preparation, also known as aromatic sulphuric acid, is useful for quenching thirst, sharpening the appetite, checking profuse perspiration, and often reducing the action of the pulse. The dose may range from ten to forty drops, administered in syrup or water.

**Elizabethgrad**, a fortified town of South Russia, in the government of Kherson, 283 miles by rail N.E. of Odessa, is an important military depot, with a strong citadel. Soap-boiling, tallow-refining, and candle-making are the principal industries. Elizabethgrad was founded in 1754, and named after the Empress Elizabeth. In 1881 there were murderous assaults on the Jews, who are very numerous here. Pop. (1883) 51,774.

**Elizabeth**, capital of Union county, New Jersey, and formerly capital of the state, lies 5 miles S.W. of Newark by rail, with one quarter (generally called Elizabethport) on Staten Island Sound. It contains a court-house, city hall, and several good schools, and is the seat of a large Singer sewing-machine factory, and of a number of manufacturing of oil-cloth, pottery, ironwares, hats, combs, &c. Elizabethport has steamboat communication with New York city, 12 miles to the north-west, and ships large quantities of anthracite coal; it also has several foundries. A great drawbridge over Staten Island Sound, 800 feet in length, with a draw-span 500 feet long, connects New Jersey here with the Staten Island shore. Pop. (1880) 28,229; (1885) 32,119.

**Elizabeth**, Queen of England and Ireland, was the daughter of Henry VIII. by his second wife, Anne Boleyn, and was born in Greenwich Palace, 7th September 1533. From her father she inherited physical strength, resolution, energy, hauteur, a fiery temper, an inclination both to cruelty and to coarseness, and a passion for splendour; to her mother may be attributed such physical attractions as can be claimed for her, whatever of feminine piquancy flashed fitfully across her essentially masculine life, and probably also her insincerity,

her jealousy, and her love of artifice. The marriage of her parents was a secret one, and when, in 1536, her mother was beheaded, and her father married Jane Seymour, she, as well as her half-sister Mary, the daughter of Catharine of Aragon, was declared illegitimate. Her early years were in consequence passed under a cloud, though profitably so far as intellectual discipline was concerned. The governesses and teachers, in whose society she spent most of her time till the death of her sister Mary, and of whom the chief were Lady Bryan, Lady Tyrwhitt, Sir John Cheke, William Grindal, and Roger Ascham, were almost all devotees to the New Learning, while some were adherents of those Reformation principles which her father partially accepted and established in England. Her accomplishments, like her charms, the ardour of her Protestantism, and even her patriotism and political foresight, were exaggerated by the historians-in-waiting of her reign. But it is beyond question that she learned to read Cicero, Sophocles, and even one or two of the Fathers in the original, to speak German and French with fluency, and to acquire a mastery over the then limited *technique* of music.

During the life of Elizabeth's father, two of her stepmothers, Anne of Cleves and Catharine Parr, looked upon her with a friendly eye, and the latter, but for her father's temper or dislike, would have had her much at court during the closing years of his reign. But till, on the death of Mary, she ascended the throne, she did not play an important part in English politics. During the reign of Edward VI. she, then a girl of sixteen, was subjected to the dubious attentions of Lord Seymour, High Admiral of England, and responded so far to them that her conduct was made the subject of a public inquiry. On her brother's death she took the side of her sister against Lady Jane Grey and the Duke of Northumberland, but her identification with Protestantism aroused the suspicion of Mary and her counsellors, and led to her being implicated in Wyatt's rebellion in 1554, and thrown into the Tower. Subsequently, she was strictly guarded in Woodstock, and her adroit and seemingly not altogether insincere conformity to the Catholic ritual was probably the sole cause of her not sharing the fate of the leading Protestants of the time, and being sent to the block.

On the death of Mary, 17th November 1558, Elizabeth, then twenty-five years of age, was summoned to the throne amid the acclamation alike of Protestants, who saw in her advent a cessation to the persecutions of the preceding five years, and of Catholics, who had more than a suspicion of her indifferentism in ecclesiastical and theological matters. Although to the end of her life she retained a liking for the splendour of Catholic ceremonial, and had no sympathy with the doctrines of Geneva, her political sagacity enabled her at once to perceive that her part in Europe must be that of a Protestant sovereign, while her courage led her to act promptly. Having presumably taken the advice of Sir William Cecil (afterwards Lord Burghley), whom three days after her accession to the throne she appointed Chief Secretary, she issued a proclamation to the effect that the church service be read in English, and the elevation of the host be discontinued. She also ordered the English ambassador at Rome to notify to the reigning pontiff, Paul IV., her acceptance of the throne. Paul IV. replied that Elizabeth, being illegitimate, must resign all pretensions to the crown of England, which he claimed a right to dispose of, that country being a fief of the holy see. The only result of this assumption was to make Protestantism and patriotism in England synonymous. The Anglican Church, with its Thirty-nine Articles, its Book of Common Prayer, and its acknowledgment of the

headship of the sovereign, was there and then virtually established in its present form. The change that was effected was in no sense a revolution. Of the prelates who were in office when Elizabeth began her reign, only one, Walson, Bishop of Lincoln, agreed to the innovations contained in her proclamation, but of 9000 clergy, fewer than 200 resigned their livings.

To an exceptional extent, even for a sovereign with such strong absolutist instincts as Elizabeth, her life was bound up with the history of England (q.v.). Here, therefore, it will be necessary only to point out how her personal prejudices and opinions, and still more, her likes and dislikes, affected the policy of her country. The great blot upon her reign were the persecution of the Catholics, and the execution of Mary, Queen of Scots. It is impossible to say now how much feminine jealousy on Elizabeth's part of a woman with greater personal attractions than herself had to do with the precipitation of this tragedy, but it is unquestionable that such jealousy existed. The discovery of designs against her life, such as the Ridolfi plot, had probably also not a little to do with her final determination, and certainly led to the execution of the Duke of Norfolk. The great glory of Elizabeth's reign, on the other hand, was the destruction of the Spanish Armada in 1588; but for this great national deliverance but slight credit is due to Elizabeth. It is true that, when an army assembled at Tilbury to resist invasion, she showed the courage of her race, and addressed her troops in language which has the genuine ring of patriotism. But it is also true that she at first declined to admit the national danger, although it was apparent to all her advisers, that she hesitated lamentably as to the steps to be taken to meet it, and that her parsimony in such matters as the naval commissariat led to the risk of disaster, and prevented the victory which was actually won from being so complete as otherwise it would have been. The triumph of England over Spain is to be attributed to the wisdom and energy of Elizabeth's advisers, to the skill and courage of the great English captains of the time, and to the generous patriotism of English, and especially of London, merchants.

It would be difficult to say whether the romantic side of Elizabeth's life is more notable for its prominence or for its fancifulness, if not unreality. From her sixteenth year to her fifty-sixth, one matrimonial scheme or violent passion, not always remarkable for delicacy, succeeded another. Before she ascended the throne, her name was mentioned in connection either with marriage or with love, not only with Admiral Lord Seymour, as already mentioned, but with Edward Courtenay, son of the Earl of Devonshire; the Earl of Arran; Philip of Spain, who married Mary; and Philibert of Savoy. After she became Queen of England, Philip renewed his courtship, while her hand was also solicited by or for Eric, king of Sweden, Henry III. of France, his successor Henry of Navarre, the Archduke Charles of Austria, and the Duke of Alençon. Letters preserved in Hatfield show that she cherished an attachment for the last until he died, worn out with debauchery, in 1584; although at the time they first met she was thirty-eight and he nineteen, and a dwarf with a face horribly disfigured by smallpox. But her heart was most profoundly touched by Robert Dudley, Earl of Leicester (q.v.), master of the horse, an accomplished courtier, and a handsome and clever, though dissolute and essentially shallow man. She indicated her partiality for him even before the death of his wife, the ill-fated Amy Robsart. The despatches of the Bishop of Aquila, ambassador of Philip II. in London, represent her indeed as accessory to the 'murder' of Amy, and as being willing to become

a Roman Catholic, provided Philip consented to her marriage with Leicester. But the bishop violently disliked Elizabeth, and there is every reason to believe that he was befooled by her, while it is by no means certain that the death of Leicester's wife was the result of foul play. But it is unquestionable that Elizabeth would have married Dudley but for the remonstrances of her chief adviser, the elder Cecil. After Leicester's death, Robert Devereux, second Earl of Essex (q.v.), succeeded to his position as favourite. But Elizabeth's relations towards Essex, as indicated by outbursts of temper as well as of affection, were essentially those of a mother towards a spoiled child. When Essex was beleaguered for rebellion in 1601 she does not seem to have exhibited much grief. The eccentricity of Elizabeth was shown even more in her passion for adulation and extravagance in dress than in her coquettishness. Raleigh felt constrained to compare her in a breath to Alexander, Diana, Venus, Orpheus, an angel, and a nymph. She is Shakespeare's 'fair vestal throned by the west,' and Spenser's Gloriana. Paul Hentzner, a German, who saw her going to chapel when she was in her sixty-fifth year, says that at that time she 'had pearls with rich drops in her ears, wore false red hair, had a small crown on her head, her bosom uncovered, her dress white silk, bordered with pearls of the size of beans, a collar of gold and jewels.' So long as she retained any activity she attended theatrical and other pageants; and the more splendid these were, the more they were to her taste. The vigorous style of her dancing was commented on sarcastically by her enemies. The variety and number of her dresses have passed into a proverb. When every allowance has been made for the manner in which Elizabeth's charms were enhanced by her own artifices, and by the flattery of her courtiers, she must still be believed to have had some personal attractions. When young she was noted for her abundance of auburn hair and mobile though regular features, while Hentzner found her 'stately and majestic,' and remarked 'a special beauty in her delicate white hands.'

Patriotic as Elizabeth was after her own peculiar fashion, she was outside of and had no sympathy with either the intellectual or the religious movements of her time. Protestantism in the form of Puritanism she abhorred; she was indifferent to the genius of Shakespeare, though his plays were performed before her. She never advanced beyond the essentially classical studies of her girlhood; yet, in virtue mainly of translations from Greek, Latin, and French, she has been included by Horace Walpole in his *Catalogue of Royal and Noble Authors*.

A personal interest attaches to the last years of Elizabeth's reign, owing to her great loneliness. This was due in large measure to the fact that her leading advisers and friends, including Burghley, Walsingham, Hatton, Bacon, and Warwick, predeceased her. Their places were taken by other men of ability, Sir Robert Cecil, Burghley's second son, being in particular both a skilful diplomatist and an accommodating courtier. But she never was on exactly the same terms with them as she had been with their predecessors. She also felt lonely in a political sense. She had inherited Tudor views as to the absolute supremacy of the crown over parliament. During the last thirteen years of her reign parliament assembled three times, in 1592, 1597, and 1601, and although, partly owing to her tact and partly to its timidity, no actual collision occurred between them, it protested against monopolies, and sought to curtail Elizabeth's expenditure. With such manifestations of public spirit Elizabeth could have no sympathy, and indeed she felt somewhat of a stranger in her own country, and among a

people whose intellectual, religious, and even political ideas were widely different from, and in some cases diametrically opposed to her own. Nevertheless, her indomitable spirit enabled her to retain her zest for the pleasures of life; to the last, too, she retained her indifference to the sufferings of others. As late as the year 1601 she was able to give receptions, to visit at the country-houses of wealthy subjects, and even to comport herself after the fashion of a boydenish school-girl. Within a few weeks of her death a seminary priest of the name of Richardson was hanged and disembowelled at Tyburn. In the beginning of 1602 those immediately about her noticed a decline in her health. She revived temporarily, however, and was able to ride, hunt, and even dance once more. In the second week of 1603 she caught cold, and never recovered. In February she was seized with sickness, which was aggravated by melancholy. She would take no medicine and little food, refused to go to bed, and rested in silence day and night on cushions. She continued in this condition till March 24, when she died in the presence of her council. She had previously made a sign with her hands in answer to a question by Cecil, which was interpreted as indicating her wish to be succeeded by James VI. of Scotland.

'The golden days of good Queen Bess' are more than ever regarded as one of those periods of British history of which we have as a nation much reason to be proud. It is emphatically the period in which Great Britain took up her position as a 'world power,' and it is impossible to believe that Elizabeth had no personal part in making it what it was. The 'Virgin Queen' nearly stands revealed by history as cruel, capricious, insincere, at once unpleasantly masculine and weakly feminine, but she was highly popular with her subjects, and this popularity cannot be quite explained away by circumstances outside of herself. She had unquestionably the invaluable faculty—in her case it amounted almost to genius—of selecting as her advisers on political affairs the most capable of the men around her.

Of the many biographies of Elizabeth, Miss Strickland's *Life* is, on the personal side, the best; M. Wiesener's *La Jeunesse d'Elizabeth d'Angleterre* (Paris, 1878; Eng. trans. 1879) may also be consulted. The most reliable authorities on the public events of her reign are the calendars of the state papers, especially the calendar of the MSS. at Hatfield, and the calendar (1509-1603) of the state papers relating to Scotland. Among historical works dealing with this period, Mr. Freuden's, in spite of the doubts which have been thrown on his accuracy by able critics, is still the best and most exhaustive. Hallam, Lingard, Birch's *Reign of Queen Elizabeth* (1754), Wright's *Queen Elizabeth and her Times* (1838), Dean Church's *Elizabeth* (1889), and Motley's *Rise of the Dutch Republic and History of the United Netherlands* should also be consulted. Essays on Elizabeth are innumerable; that of Dr. Jessopp (1889), contributed to *The Dictionary of National Biography*, will be found exceptionally bright and comprehensive. See also the articles MARY, QUEEN OF SCOTS; BURGHELY, ARMAVA, LINDSEY, ESSEX, DRAKE, RALEIGH; and for the Elizabethan literature, see ENGLAND (LITERATURE OF), and DRAMA.

**Elizabeth**, Queen of Bohemia, forms the connecting link between the ancient royal families of England and Scotland and the present reigning dynasty. Daughter of James VI. of Scotland and I. of England, she was born in the palace of Falkland, 19th August 1596, educated in England, and in 1613 married to Frederick V. (q.v.), Elector Palatine, who in 1619 was chosen by the Bohemian estates to fill the throne of Bohemia. The following year the army of the 'Winter King' was routed by the forces of the Catholic League, and the royal family took refuge in Holland, where they had to endure sore poverty. Of the

thirteen children of Elizabeth, mention may be made of Charles Louis, who was restored to the hereditary electorate at the close of the Thirty Years' War in 1648; Rupert, the 'mad cavalier'; Maurice, who also fought in England during the Civil War; and Sophia, who was married to Ernest Augustus of the House of Brunswick, afterwards Elector of Hanover. After the Restoration Elizabeth went to England, where she died February 13, 1662. When in 1701 the question of succession to the crown of Great Britain was debated, it was found that all the descendants of James I. were either dead or were Roman Catholics, except Sophia, Electress of Hanover, and her family. By act of parliament the crown was accordingly secured to her and her descendants, 'being Protestants'; and in virtue of this Act of Settlement, on the death of Queen Anne Sophia would have ascended the throne, but she predeceased the queen three months, and her son became king of Great Britain as George I., August 12, 1714. In this extraordinary and unforeseen manner did the unfortunate queen of Bohemia originate the dynasty of the reigning monarch. In her prosperity fond of luxury and magnificence, in adversity a devoted wife and mother, she was always resolute and vivacious, and exercised a singular charm over her contemporaries. See her *Life* in *Mrs Everett Green's Lives of the Princesses of England* (1851); Gardiner's *History of England*; and the *Memoirs of Sophia, Electress of Hanover* (trans. 1889).

**Elizabeth**, MADAME (1764-94), a French princess, sister of Louis XVI. (q.v.).

**Elizabeth**, ST., daughter of Andreas II., king of Hungary, was born at Presburg in 1207. At the age of four she was affianced to the Landgraf of Thuringia, Louis IV., and brought to his court in the Wartburg near Eisenach to be educated under the eyes of the parents of her future husband. She early displayed a passion for the severities of the Christian life. She despised pomp, and ambition, cultivated humility, and exhibited the most self-denying benevolence; her conduct even as a girl astonished the Thuringian court. The marriage took place when Elizabeth was only fourteen. Louis himself, far from blaming the devout girl whom he had made his wife for her long prayers and ceaseless almsgiving, was himself partially attracted to a similar mode of life. A boy and two girls were the fruit of their union. Louis died as a crusader at Otranto in 1227. Great misfortunes soon befell the saintly landgravine. She was deprived of her regency by the brother of her deceased husband, and driven out of her dominions on the plea that she wasted the treasures of the state by her charities. At last she found refuge in a church, where her first care was to thank God that he had judged her worthy to suffer. Subsequently, after other severe privations, such as being forced to take up her abode in the stable of a hostelry, she was received into the monastery of Kitzingen by the abbess, who was her aunt. When the warriors who had attended her husband in the crusade returned from the East, she gathered them round her, and recounted her sufferings. Steps were taken to restore to the unfortunate princess her sovereign rights. She declined the regency, however, and would only accept the revenues which accrued to her as landgravine. The representations of other potentates soon induced her brother-in-law to allow her to return to Marburg, and to draw a yearly revenue of 500 marks. She now devoted herself wholly to a life of asceticism, put on nun's raiment, and took up her residence in a cottage at the foot of the hill on which stood her castle of Marburg. The remainder of her days were

devoted to incessant devotions, almsgivings, and mortifications. All her revenues were given to the poor, and what she required she earned with her own hands. She died 19th November 1231, and was canonised four years after by Pope Gregory I. Miracles surrounded her even during her lifetime; thus a basket conveying provisions to the poor, when opened by a suspicious person, was found to contain nothing but roses. Above her grave at Marburg the beautiful Elisabethkirche was founded in 1236. See Montalembert's *Histoire de Sainte Elisabeth de Hongrie* (1836; 17th ed. 1880). Kingsley's *Saint's Tragedy* (1848) is based on the story of Elizabeth's life.

**Elizabethan Architecture**, a term applied to the mixed style which sprang up on the decline of Gothic architecture. It is chiefly exemplified by mansions erected for the nobility in the reigns of Elizabeth and James I., and originated in the first attempt to revive classic architecture. This tendency came from abroad, and was influenced, no doubt, by Holbein, who was patronised by

Holland House.

Henry VIII., and furnished several designs in this manner. John of Padua succeeded him, and built in the mixed style a palace for the Protector Somerset (for which purpose the cloisters of St Paul's were taken down), and the mansion of Longleat for his secretary, Sir John Thynne. At first the classic forms were applied to the details only, and the old English design was preserved, both as regards the plan and general aspect of the exterior; but by degrees the classic taste pervaded the whole design. Thus the bow-windows and turrets of the Tudor style are preserved, but their decoration is treated with classic cornices and pilasters instead of Gothic enrichments. The vast dimensions of the apartments, the extreme length of the galleries, and enormous square windows are leading characteristics of this manner of building. The ornaments both within and without were cumbersome but picturesque, while the plaster ceilings wrought into compartments are amongst the most original and striking features. In short, the architecture was in keeping with the dress of the period, rich and gorgeously, rather than elegant and graceful; but the domestic arrangements and general planning of the houses were carried to a degree of completeness and comfort which has scarcely been exceeded since. The following examples of mansions of the 17th century may be still seen near London: Holland House, Campden House, Sir T. Willow's at Charlton, the Marquis of Salisbury's at Hatfield, and Knowle, the property of the Duke of Dorset. The most eminent architects of those times were John Thorpe, Gerard Christmas, Rodolph Symonds, and Thomas Holt.

**Elizabeth Petrovna**, Empress of Russia, daughter of Peter the Great and Catharine I., was born in the year 1709. Of doubtful legitimacy, and apparently indifferent to everything but the gratification of her passions, she did not oppose the accession of the boy Peter II. in 1727, of Anna, Duchess of Courland, in 1730, and of the infant Ivan VI. in 1740. In 1741 the infant emperor was deposed, and Elizabeth raised to the throne, chiefly by the agency of Leecq, a surgeon, and the Marquis de Chetardie, the French ambassador. In the following year Elizabeth proclaimed as her successor Peter, the son of her sister the Duchess of Holstein-Gottorp. During this reign a war with Sweden was brought to a successful conclusion by the peace of Abo. The anti-Prussian policy of her advisers and her personal animosity towards Frederick II. led her to take part in the war of the Austrian Succession and in the Seven Years' War, before the close of which she died in January 1762. Though profligate in conduct, she was strict in the observance of the public ordinances of religion. Averse to business, she was guided by favourites, while corruption prevailed in every department of the state. She founded the university of Moscow and the Academy of Art at St Petersburg.

**Elizabethpol**, a town of Russian Transcaucasia, is situated on a tributary of the Kur, at an altitude of 1450 feet. Its streets are narrow and its houses mean, but it has several mosques and churches, the mosque of Shah Abbas being particularly fine. Elizabethpol is not a healthy town; its inhabitants, about 19,000 in number, are compelled to retire to the hills in summer. The town and its vicinity are famous for their fruit-trees; and horticulture, the breeding of silkworms, and agriculture are the chief industries of the place. Elizabethpol was formerly known as Gansha or Kanga, and belonged to the Turks. The modern town was founded by Shah Abbas of Persia, but fell into the hands of the Russians in 1804. On 25th September 1826 the Persians were defeated here by the Russians under Paskevitch.

**Elk**, or **MOOSE** (*Alces machlis*, or *palmatus*), the largest living deer, a magnificent animal of circum-polar distribution, in Europe, Asia, and especially in America. It is the only species of its genus or sub-genus, but is nearly allied to *Cervus* (see DEER). It must be distinguished from the Wapiti (*Cervus canadensis*), with which it is often, verbally at least, confused. The adult elk usually stands about six feet high at the shoulders, and may exceed even this noble stature. The male bears very broad (palmate) divergent antlers, with which it has been known to kill a wolf at a single blow. The general colour is dark reddish-brown, but becomes slightly lighter and grayer in winter. The limbs, especially the fore-legs, are very long, and as the neck is short, the elk browses more upon bushes and the like than upon the ground herbage, which it is but little adapted to reach. The tail is very small. More detailed characters are the broad hairy nostrils, the overhanging upper lip, the small

Head of Elk (*Alces machlis*).

eyes and tear-pits, the long and broad ears, the low stiff mane on the back of the neck, the loose mane on the lower side of the neck and on the breast, the long brittle hair, &c. The antlers form between them a sort of basin, for each broadens out in a great shovel-shaped expansion, with marginal prongs or snags, increasing as usual with the years of life. The entire 'head'—i.e. the pair of antlers, sometimes weighs 40 lb., while adult animals are said to weigh in all about 10 cwt. The young male elks do not begin to acquire antlers till they are nine months old, and growth seems to go on for fourteen years. The younger elks are also marked by a large goutre-like swelling under the throat.

Elks are for the most part solitary in their habits, except at the breeding season. They delight in marshy places and in forests. The widely separating halves of the hoof enable them to find firmer foothold in soft ground or among snow. In the forest, their magnificent antlers, as Mr Darwin notes, must sometimes be rather in the way than otherwise. When walking leisurely, they carry themselves so well that entanglement is avoided, but it is easy to see how the case is altered when, with head thrown back, they flee before the wolves. The usual gait is a shambling trot, but the elk can also gallop rapidly. Only when the deep snow impedes it are the hunters, aided with snow-shoes, able to run it down. The usual method of hunting is to stand upon the elk as it rests, but as its senses are extremely acute and the trails often confused, successful capture is regarded as a feat. Naturally timid and inoffensive, the disposition changes in the breeding season. The male elks fight with one another, and are at that season sometimes decoyed to the hunter, who imitates the sounds of a rival. As the elk is then furious, this device demands strong nerve and sure aim.

The European and Asiatic distribution of the elk is now much restricted. In Germany, for instance, they were abundant in the time of Cæsar, but are now all but extinct. In the Baltic provinces, in

on leaves, buds, and bark, it does considerable damage to forest trees.

**Elk, IRISH** (*Megaceros giganteus* or *hibernicus*), a giant deer now extinct, known from the remains found in the Pleistocene diluvium of Middle Europe, Britain, and especially Ireland. It must have been a magnificent animal, standing about 6 feet high at the shoulders, and probably very like a fallow-deer. The antlers formed the most striking feature. They have their own peculiarities, but recall in part those of the quite distinct modern elk, and also those of the fallow-deer. Antlers have been found 5 feet in length, while a straight line drawn between the extreme tips in one specimen measured 10 feet 10 inches. In a specimen where the skull alone weighed 5½ lb, the antlers weighed 81 lb. Associated with such an enormous head-growth we naturally find large and strong neck vertebrae and fore-limbs. The skeletons are to be seen in most museums. See DEER.

**Elkesaites.** See EBIONITES.

**El-khargeh.** See OASES.

**Elkhart,** a town of Indiana, at the junction of the St Joseph and Elkhart rivers, 101 miles E. by S. of Chicago by rail, with a rolling-mill, several planing-mills, machine-shops, and railway workshops, and manufactures of paper, flour, and starch. Pop. 6953.

**El** (allied to *elbow*, Ger. *ellenbogen*, Lat. *ulna*, 'the forearm'), a measure originally taken in some vague way from the arm, and which has been used to denote very different lengths. The English *ell*, as a measure of cloth, is equal to 1½ yard (q.v.), the Flemish to ¾ yard, and the French to 1½ yard.

**Elland,** a town in the West Riding of Yorkshire, on the river Calder, 3 miles S.E. of Halifax by rail. It has some cloth-mills, and there are valuable stone-quarries in the vicinity. Pop. 8278.

**Ellenborough, EARL OF.** Edward Law, first Earl of Ellenborough, was eldest son of the first Baron Ellenborough (1750-1818), Chief-justice from 1802 of the King's Bench. Born 8th September 1790, he entered parliament in 1813, held office under several administrations, and in 1841 was appointed Governor-general of India. He received the thanks of parliament in 1843 for his 'ability and judgment' in supporting the military operations in Afghanistan, but his treatment of the civil servants of the Company, and his policy of conciliating the natives by oriental display and proclamations which appeared to sanction idolatry, led to his recall in 1844. Supported by the ministry, he was created Viscount Southam and Earl of Ellenborough, and in 1846 was First Lord of the Admiralty under Peel. In the Derby administration of 1858 he was Minister for India, but the publication of a despatch in which he severely rebuked Viscount Canning forced him to resign in order to avert the overthrow of the government. He afterwards took a frequent and influential part in the debates of the Upper House. In 1863 he expressed strongly his sympathies on behalf of Poland, and in 1864 advocated British intervention in favour of Denmark. Ellenborough died without issue, December 2, 1871, when the barony devolved on a nephew, but the earldom and viscounty became extinct. See *History of the Indian Administration of Lord Ellenborough*, by Lord Colechester (1874), who also edited his *Political Diary, 1823-80* (1881).

**Ellery, WILLIAM** (1727-1820), born in Newport, Rhode Island, sat in the congress of 1776, and was one of the signers of the Declaration of Independence. From 1790 till his death he retained the office of collector in his native place.

**Ellesmere,** a town of Shropshire, near a beautiful lake or mere of 120 acres, 19 miles NNW.

Skeleton of Irish Elk (*Megaceros hibernicus*):  
Height to summit of antlers, 10 feet 4 inches.

Northern Russia, in Norway and Sweden, they still occur, but not in the abundance which is still exhibited in North America. Domestication has been tried with success, and the animal trained to the sledgo. The flesh is esteemed a good kind of venison; the fat is remarkably soft; the nose and tongue are reckoned delicacies. The skin is used for a variety of purposes. As the elk feeds largely

of Shrewsbury. Pop. 1875. The Ellesmere Canal, connecting the Severn and the Mersey, passes here. It is carried across the Dee and the Vale of Llangollen by Telford's Ellesmere Aqueduct (1805), 1007 feet long and 127 high. Ellesmere Port, at its mouth, on the Mersey, is a station on the line of the Manchester Ship Canal.

**Ellesmere**, FRANCIS EGERTON, first EARL OF, was second son of the first Duke of Sutherland, and was born in London, 1st January 1800. Educated at Eton and Christ Church, Oxford, he sat for Bletchingley, Sutherland, and South Lancashire, and successively (1828-30) held the offices of Irish Secretary and Secretary for War. In 1833, on succeeding to his father's Bridgewater estates, he assumed the name of Egerton, in lieu of his patronymic Leveson-Gower, and in 1846 became Earl of Ellesmere and Viscount Brackley. He translated *Faust* fairly, published an interesting record of his travels, and was a generous patron of the arts. He died 18th February 1857.

**Ellice Islands** are in the South Pacific, due N. of Fiji, and SW. of Samoa; extending for some 360 miles from NW. to SE. between 3½° and 11° S. lat., and 176° and 180° E. long. They consist of nine groups of atolls or coral islands, one of which groups, known specially as Ellice Islands (the main island in it being Funafuti), was discovered in March 1819 by the American Captain Peyster, in the *Rebecca*. Another of the atolls had previously been discovered in 1781. The population of this whole archipelago, exclusive of Samoan missionaries and a few white traders, has been given at about 2500 Polynesians, mostly Christianised. Like the people of Samoa and Tonga, they have a fine physique, and are peaceable in disposition. The islands grow little but cocoa-nut trees, copra being the main export. They have not been annexed by any European power, and British subjects within their limits are subject to the jurisdiction of the High Commissioner for the Western Pacific.

**Ellichpur**, chief town of a district (area, 2023 sq. m.; pop. 313,805) of the same name, in the north of Berar, was at one time capital of the Deccan, and is said to have contained 40,000 houses. Its buildings include an extensive palace (fast falling to ruin), a detached fort, the burial shrine of Dulla Ráhmán, and several handsome tombs of the nawábs. The military cantonment of Paratvada is 2 miles distant. Pop. (1881) 26,728, with a force of 9445 troops.

**Ellicott**, CHARLES JOHN, Bishop of Gloucester and Bristol, was born 25th April 1819, at Whitwell, near Stamford, of which parish his father was rector. He was educated at Oakham and Stamford schools, and at the university of Cambridge, where he graduated in 1841, and was elected fellow of St John's College. He became rector of Pilton, Rutlandshire, in 1848, professor of Divinity at King's College, London, in 1858, Hulsean lecturer at Cambridge in 1859, and Hulsean professor of Divinity the year after. He was nominated Dean of Exeter in 1861, and raised to the episcopal bench in 1863. His episcopate has been honourably distinguished by the most vigorous and catholic-spirited activity in educational, missionary, and church extension work. Dr Ellicott was chairman for eleven years of the New Testament Revision Committee. He is best known as a commentator on the Epistles of the New Testament, and is distinguished for thoroughness of grammatical criticism. He has published critical and grammatical commentaries on Galatians (1854), Ephesians (1855), Philippians, Colossians, Thessalonians, Philemon, and the Pastoral Epistles (1861); works on the Sabbath, on Scripture and its Interpretation, and on Modern Scepticism. A useful work which he

has edited is *A New Testament Commentary for English Readers* (3 vols.), and a corresponding work on the *Old Testament* (5 vols.).

**Elliot**, JEAN, the author of 'The Flowers of the Forest,' a touching lyric on the disaster of Flodden, was the daughter of Sir Gilbert Elliot of Minto House, Teviotdale, where she was born in 1727. The greater part of her life was spent in Edinburgh (1756-1804). She died at the family seat or at Monteriot, on 29th March 1805. Her eldest brother, Sir Gilbert Elliot (1722-77), was himself a song-writer; whilst John, the third brother, who died in 1808, was a distinguished admiral. See MINTO.

**Elliotson**, JOHN, an English physician, was born in London in 1791. After leaving Jesus College, Cambridge, he studied medicine at Edinburgh and London, and was for five years assistant physician at Guy's Hospital. In 1831 he became professor of the practice of medicine in the university of London, and took an active share in the establishment of University College Hospital. He was at this time one of the foremost physicians of London, and a successful lecturer. In 1837 he became a convert to mesmerism, which cost him his professorship in 1838, but did not apparently much diminish his private practice. He died in London on 20th July 1868. Besides being one of the first to use the stethoscope, Elliotson conducted numerous useful experiments as to the action of drugs, and did much to encourage the practice of clinical study. He was the founder of the Phrenological Society. His name will live securely from its connection with Thackeray's *Pendennis*.

**Elliott**, EBENEZER, the Corn-law Rhymmer, was born of mixed moss-trooper and yeoman ancestry at the New Foundry, Mashbo', in Rotherham parish, Yorkshire, on 17th March 1781. A shy and morbid boy, who proved a dull pupil at four different schools, he worked in his father's foundry from his sixteenth to his twenty-third year, and threatened to become a 'sad drunken dog,' till the picture of a primrose in Sowerby's *Botany* 'led him into the fields, and poetry followed.' His *Vernal Walk*, written at sixteen, was published in 1801; to it succeeded *Night* (1818), *The Village Patriarch* (1829), *Corn-law Rhymes and the Ranter* (3d ed. 1831), and other volumes—collected in 1840 (new ed. 2 vols. 1876). He had married early, and snuk all his wife's fortune in his father's business; but in 1821, with a borrowed capital of £100, he started on his own account as a bar-iron merchant at Sheffield, and thrrove exceedingly, 'making £20 a day sometimes without stirring from his counting-house, or ever seeing the goods he disposed of.' Though in 1837 he lost fully one-third of his savings, still in 1841 he was able to retire with good £300 a year to a house of his own building at Great Houghton, near Barnsley. Here he died 1st December 1849.

Elliott the poet is well-nigh forgotten. His poems are nowadays little more read than in his lifetime was his tragedy *Taurasdes*. It had three readers, Elliott one of them. But Elliott the Corn-law Rhymmer is still remembered as the Tyrtæus of that mighty conflict whose triumph he lived to witness, as the typical maker of ballads, not needing to care who should make the laws of the nation. This Corn-law Rhymmer had been bred a 'Berean' and Jacobin; yet he hated Communists, Socialists, and physical-force Chartists; he lies buried in Darfield churchyard; he left two sons Established clergymen. His whole life long he looked on the Corn-laws as the 'cause of all the crime that is committed'; agriculturists, he maintained, 'ought not to live by robbing and murdering the manufacturers.' On the other hand, 'Capital has a

right to rule the world,' and 'competition is the great social law of God.'

There are two poor memoirs of Elliott, by his son-in-law, John Watkins (1850), and by 'January Searle'—i.e. George S. Phillips (1850). See also Carlyle's essay from the *Edinburgh* for July 1832, and Professor Dowden in Ward's *English Poets* (2d ed. 1883).

**Elliott, GENERAL.** See HEATHFIELD (LORD).

**Ellipse**, a geometrical curve and figure, intermediate to the circle and parabola (see CONIC SECTIONS). It is of great importance in Astronomy, being the shape of the orbit described by a planet under the action of gravitation. Mathematically, the ellipse is a closed curve, every point of which has the sum of its distances from two fixed points always the same. These two fixed points are called the foci; and the diameter drawn through them is the major axis; the minor axis bisects the major at right angles. The distance of either focus from the middle of the major axis is the *eccentricity*. The less the eccentricity, as compared with the axis, the nearer the figure approaches to a circle. When the foci coincide the ellipse becomes a circle, and when they are infinitely apart it becomes a parabola. The tangent at any point of the curve is always equally inclined to the two focal distances; and any diameter bisects all the chords which are parallel to the tangents at its extremities.

The Trammel or Elliptic Compass affords the easiest way of drawing an ellipse. It depends on

the principle that when a line of fixed length moves so that its extremities are always on two fixed perpendicular lines, any point in it must describe an ellipse. A simple practical method is by passing a loop of thread over two pins stuck in the foci, *Ss* in the diagram, the length of the loop being equal to *SB*. If the point of a pencil is put into the loop *P*, and moved round so as to keep it stretched, the pencil will trace an ellipse *ALBD*. There are also various ways of approximating to the figure by the use of circular arcs.

The equation to an ellipse (see GEOMETRY, ANALYTICAL), referred to its centre as origin, and to its major and minor axes as rectangular axes, is  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ , where *a* and *b* are the semi-major and semi-minor axes respectively. From this equation it may be shown, by the integral calculus, that the area of an ellipse is equal to  $\pi ab$ ; or is got by multiplying the product of the semi-major and semi-minor axes by 3.1416. It may also be shown that the length of the circumference of an ellipse is got by multiplying the major axis by the quantity  $\pi \left\{ 1 - \left( \frac{1}{2} \right)^2 \frac{e^2}{1} - \left( \frac{1.3}{2.4} \right)^2 \frac{e^4}{3} - \left( \frac{1.3.5}{2.4.6} \right)^2 \frac{e^6}{5} - \&c. \right\}$  to which there is an excellent practical approximation, viz.,  $\frac{\pi}{2} (a + b \sqrt{2(a^2 + b^2)})$ . The eccentricity, *e*, is  $= \sqrt{1 - \frac{b^2}{a^2}}$  and the *ellipticity* is the ratio *a* - *b* to *a*.

**Ellipsis** (Gr., 'omission') is a term used in Grammar and Rhetoric, to signify the omission of a word necessary to complete the expression or sentence in its usual form. The object of ellipsis is shortness and impressiveness; accordingly, it prevails in proverbs. Ellipses are used in all languages, but the same forms of ellipses are not common to all.

**Ellipsoids** are of two kinds, the simpler being those of revolution, produced by an ellipse turning round the major or the minor axis. The surfaces so generated are known as prolate and oblate spheroids respectively, and our globe is a well-known instance of the latter. The ellipsoid proper has three rectangular axes of different lengths, and its section in any direction is an *ellipse*, whereas the spheroids must give a circular section if cut at right angles to the axis of revolution.

**Ellis, ALEXANDER JOHN** (formerly Sharpe, the name having been changed by royal license in 1825), a learned philologist, was born on the 14th June 1814, and educated at Shrewsbury, Eton, and Trinity College, Cambridge, where he graduated sixth wrangler in 1837. He was elected a Fellow of the Royal Society in 1864, and of the Society of Antiquaries in 1870, was president of the Philological Society during 1872-74, and also 1880-82, and is a member of the Mathematical Society of London. He has written numberless papers of great learning on mathematical, musical, and philological questions, and has done more than any other scholar to advance the scientific study of phonetics, of early English pronunciation, and of existing English dialects. Of his many and valuable books the most important are *Essentials of Phonetics* (1848); *Universal Writing and Printing* (1856); *Early English Pronunciation, with especial reference to Chaucer and Shakespeare* (6 parts, 1869-89); *Practical Hints on the Quantitative Pronunciation of Latin* (1874); and a translation of Helmholtz's *Sensations of Tone* (1875; 2d. ed. 1885). This esteemed contributor to the present work died 28th October 1890.

**Ellis, SIR HENRY**, antiquary, born in London in 1777, was educated at Merchant Taylors' School, and at St John's College, Oxford, of which he became a Fellow. Having been for some time assistant-librarian to the Bodleian at Oxford, in 1800 he received an appointment at the British Museum, of which he became principal librarian in 1827. He received the honour of knighthood from William IV. in 1833. Ellis retired from the museum in 1856. He was for many years director, and one of the secretaries, of the Society of Antiquaries. His *Introduction to Domesday Book* was published in 1833; his *Original Letters Illustrative of English History*, issued in three series, in the years 1824-46; and his invaluable edition of Brand's *Antiquities*, in 1813. He was likewise the author of a *History of the Parish of St Leonard, Shoreditch*, and of works on the Townley and Elgin Marbles, and was the chief editor and writer of the English portion of the edition of Dugdale's *Monasticon* (1817-30). His works exhibit much learning and research. He died in London, 15th January 1869.

**Ellis, WILLIAM**, an eminent English missionary, was born in London, 29th August 1794. He was brought up as a gardener, but having offered himself to the London Missionary Society, was trained and despatched in 1816 to the South Sea Islands, where he laboured for nearly ten years, first at Bimeo, next at Oahu, one of the Sandwich Islands. The illness of his wife obliged him to return to England in 1825, after which he became foreign secretary to the London Missionary Society. Meantime his *Tour through Hawaii* (1826) and his *Polynesian Researches* (1839) extended his fame as a missionary of rare earnestness and enthusiasm, and still rarer intelligence and breadth of sympathy. His wife died in 1835, and two years later he married Sarah Stickney, who for many years conducted a school for girls at Hoddesdon in Hertfordshire, and wrote many excellent and popular books, as *The Women of England* (1838), *The Daughters of England* (1842), *The Wives of Eng-*

land (1843), *Hearts and Homes* (1848-49), and *The Mothers of Great Men* (1859). Ellis published in 1838 a history of Madagascar, and in 1853 he was sent to that island with a view to improve the condition of the Christians there. He made four different visits to the island, the last extending over four years (1861-65), and by his tact and sagacity did much to settle the external relations of the Christians on a safe basis. His *Three Visits to Madagascar* (1858), *Madagascar Revisited* (1867), and *The Martyr Church of Madagascar* (1870), besides their personal and religious interest, are still the best books we possess on the history, the scenery, the productions, and the people of Madagascar. Ellis died 9th June 1872; his wife, but a week later. See the Life by his son (1873).

**Elliston**, ROBERT WILLIAM, actor, was born in London, the son of a watchmaker, in 1774, and was educated at the expense of his uncle, who was master of Sidney College, Cambridge. In 1791 he ran away from home, and made his first appearance on the stage at Bath, where his *Romeo* in 1793 lifted him into public favour. In 1796 he appeared at the Haymarket and Covent Garden; and after 1803 he made London his headquarters, though still making occasional essays as a provincial manager. He was a member of the Drury Lane company in 1804-9 and 1812-15; in 1819 he became lessee and manager of the theatre, from which, in 1826, he retired a bankrupt. He afterwards played in the Swaney Theatre; but years of dissipation had shattered his health, and an apoplectic seizure brought on his death, 8th July 1831. Elliston was an actor of wonderful versatility, the first comedian and one of the first tragedians of his day, and in Leigh Hunt's estimation the 'best lover on the stage both in tragedy and comedy;'

wonderful rock-cut temples. Of these there are 34 of a large size, Buddhist, Brahmanical, and Jain. Some are cave-temples proper—i.e. chambers cut out in the interior of the rock—but others are vast buildings hewn out of the solid granite of the hills, having an exterior as well as an interior architecture, and being, in fact, magnificent monoliths. In executing the latter, the process was first to sink a great quadrangular trench or pit, leaving the central mass standing, and then to hew and excavate this mass into a temple. The most beautiful of these objects is the Hindu temple, called the Kailās, dedicated to Siva. At its entrance the traveller passes into a large antechamber adorned by numerous rows of pillars. Thence he ascends a few steps into a great rectangular court, averaging 276 feet in length and 154 in width, in the centre of which stands the temple itself, a vast mass of rock richly hewn and carved. It is supported by four rows of pilasters, with colossal elephants and other animals beneath, and seems suspended in the air. The interior is about 103 feet long, 56 broad, and 17 high, but the entire exterior forms a pyramid 164 feet long, 109 wide, and 100 high, and is overlaid with sculpture. In the great court are numerous ponds, obelisks, colonnades, sphinxes, and on the walls thousands of mythological figures of all kinds, from 10 to 12 feet in height. The interior, and certainly some parts of the exterior, have been plastered over and painted. It is now generally believed that the caves date from the 7th century.

**Ellore** (*Elūr*), a town in the Godavari district, Madras, on the Jammalar River, 255 miles N. of Madras, with manufactures of woollen carpets and saltpetre. The heat is very oppressive, reaching 110° F. in the shade. Pop. 25,092.

**Ellsworth**, a port of entry in Maine, on the river Union, 28 miles SE. of Bangor, with a very large lumber trade. Pop. 3052.

**Ellwangen**, an industrial town of Wurtemberg, on the Jagst River, 55 miles N. of Ulm by rail. Pop. 4793. The old castle of Hohen-Ellwangen, close to the town, has been used as an agricultural school since 1843.

**Ellwood**, THOMAS, whose name will never be forgotten from its connection with Milton's, was born at Crowell in Oxfordshire in 1639. At twenty the influence of his friends the Penningtons converted him to Quakerism, from which neither his father's blows, nor confinement within his house, nor frequent imprisonments could cure him. In 1662 he made Milton's acquaintance, and soon visited him 'every day in the afternoon, excepting on the first day of the week, and sitting by [the poet] in his dining-room, read to him in such books in the Latin tongue as he pleased to hear me read.'

Milton taught him to read Latin in the foreign manner. The readings were interrupted six weeks later by Ellwood's illness; but again, in 1665, we find him hiring a cottage at Chalfont St Giles, where Milton might escape the plague then raging in London. One day Milton

The Kailās Temple at Ellora. (From Fergusson.)

Lamb's eulogy is well known. See the Life by Raymond (2 vols. 1845), and the article by Joseph Knight in *Diet. Nat. Biog.* (vol. xvii. 1889).

**Ellora**, a village in the Nizam's dominions, 13 miles NW. of Aurungabad. It is celebrated for its

gave him the manuscript of *Paradise Lost* to read, and when returning it Ellwood said, 'Thou hast said much of "*Paradise Lost*," but what hast thou to say of "*Paradise Found*?" When Milton handed him *Paradise Regained* in London, he added, 'This is owing to you, for you put it into my head by the question you put to me at Chalfont, which before I had not thought of.' Ellwood married in 1669, was busy in controversy, and seems to have had more than his share of the persecutions that fell upon the Quakers almost till his death in 1713. Of his many tracts, treatises, epistles, and even poems, only his Autobiography is now interesting, and that not for his own sake, but because he crossed the orbit of almost our greatest poet. An excellent and accessible edition is that in Professor Henry Morley's 'Universal Library' (1885).

**Elm**, a village of Switzerland, at the head of a mountain-gilt valley in the canton of Glarus, with 1000 inhabitants when, in 1831, the whole of the northern side of Tshingel Peak (10,230 feet) crashed down upon it, destroying a large part of it, and filling the narrow valley with the debris of the landscape.

**Elm** (*Ulmus*), a genus of trees of the natural order Ulmaceæ, natives of temperate climates, with serrated leaves unequal at the base, and small flowers growing in clusters appearing before the leaves, and containing 4-12 stamens and one germen. The fruit is a samara, or compressed one-seeded little nut, winged all around. Elm is a remarkably variable genus, so much so that botanists are greatly divided in opinion as to which are species and which varieties among the numerous forms comprised in it. There are two well-marked types common to Britain, and having a wide distribution in Europe and Western Asia and Northern Africa. Those are the English Elm (*U. campestris*), which is the most common in English woods and pleasure-grounds; and the Scotch or Wych Elm (*U. montana*), which, though more common in Scotland and in Ireland, is more sparingly distributed also in England and on the Continent.

Common English Elm (*Ulmus campestris*):  
a, flower, b, fruit.

The English elm often attains a height of from 70 to 90 feet, with a diameter of from 5 to 6 feet, before it is one hundred years old—an age that the elm-tree rarely much outlasts; it may even exceed 100 feet in height. Both species have been productive of many varieties, some of which are so distinct as to be by some considered species and by others as merely well-marked sub-species or varieties. The fact that no reliance can be placed on the progeny of any of these forms,

when reared from seed, having the features and attributes of the parent appears to corroborate the latter view. In consequence of this peculiarity in elm it is necessary, if we wish to perpetuate any specially desirable or meritorious kind, to propagate it by budding, grafting, or layering. Varieties of the English elm are numerous.

All are not alike valuable as timber-trees. For forest-planting, seedlings of the type and other well-marked kinds are selected. Besides the typical form, varieties known to nurserymen as the Broad-leaved English Elm (*U. c. latifolia*), the Red English Elm (*U. c. stricta*), and the White English Elm (*U. c. alba*) are preferred to any others as the seed parents, their progeny proving almost invariably valuable timber producers.

Of this species there are some interesting and beautiful varieties, much esteemed for their effect in ornamental grounds and garden scenery. The most distinct are the typical form with silver variegated leaves, and also with yellow variegated leaves, and *U. c. viminalis*, of which there is also a silver-leaved form, both of them being remarkable for the small, twiggy character of their shoots, and their light, elegant appearance. The Twisted Elm (*U. c. tortuosa*) is a very singular variety of French origin. Its trunk marked with alternate protuberances and hollows gives it a very remarkable appearance in old trees. Its timber is preferred in France above all others by wheelwrights, particularly for spokes, its fibre being exceedingly tough, twisted, and interlaced together. The Dutch Cork-barked Elm (*U. c. major*) is a well-marked variety or sub-species of the English elm, which was introduced by William III. when the Dutch style of gardening was fashionable. Its rapid growth and adaptability to being clipped into the stiff, formal shapes essential to that style of gardening led to its being much used while the fashion prevailed; but when Dutch gardening disappeared, the cultivation of this variety of elm almost ceased, as its timber is comparatively worthless. The bark of the younger branches is rough and cork-like. The Cork-barked English Elm (*U. c. suberosa*) is a very handsome and well-marked sub-species, growing with greater vigour and to a larger size than the type, having also larger leaves and the bark of the branches distinctly lined with corky wings.

The wood of the English elm is highly valued for its great strength, toughness, and closeness of texture. It is less liable to split than almost any other timber, and powerfully resists the decomposing action of water; it is therefore much in request for keels of ships and boats, masts and spokes of wheels, foundation piles, and wet-planking. The large bosses or knots with which the trunk is frequently covered are much prized in cabinet work and in turnery for their beautiful appearance when cut up

Common English Elm  
(*Ulmus campestris*).

and polished. The bark is used in dyeing and in sugar-refining, and in times of scarcity has been used in Norway for grinding into meal and mixing in bread. The inner bark is used medicinally in cutaneous diseases; it is mucilaginous, and has a bitter astringent taste. In Persia, Italy, and the south of France galls are frequently produced on the leaves, often of large size, containing a clear fluid called *eau d'orme*, which is sweet and viscid, and is used to wash wounds. Towards autumn these galls dry up, leaving a residue of a yellow or blackish balsam called *baume d'orme*, which was formerly in great repute for diseases of the chest. The seeds of the elm are eagerly eaten by pigeons and common poultry. A peculiar vegetable principle called *ulmin*, or *ulmic acid*, was first discovered in the substance which often spontaneously exudes from the bark of the English elm. It is a dark-brown substance, without smell or taste, insoluble in cold, sparingly soluble in boiling water, which it colours yellowish-brown, and soluble in alcohol and in alkaline solutions.

The typical form of Scotch elm is easily distinguished from the English by its less upright trunk, more spreading branches, and larger, broader leaves. The tree is generally considered more picturesque in style than the English elm. Its timber, though more liable to crack, is quite as much esteemed for its durability and toughness, and is used for nearly every purpose for which that of the English elm is in demand. The enormous bosses which frequently occur on the trunk are highly valued in cabinet-making. The varieties of this species are numerous, and some of them are important both as timber and as ornamental trees. The Smooth-leaved Wych Elm (*U. m. glabra*) is so distinct in its upright growth, smaller and smooth leaves, and other even more important characters, from the typical Wych Elm, that some are disposed to regard it as a species. It is certainly well marked, and from it have sprung the Huntingdon Elm, the Chichester Elm, and the Scampston Elm, all of which have a strong resemblance to each other, and are remarkable for their great rapidity of growth and their value as timber-trees. Of ornamental and curious varieties, the Wych Elm is the parent of several, the more remarkable of which are the Weeping Wych Elm (*U. m. pendula*), the Exeter Wych Elm (*U. m. fastigiata*), and the Variegated Wych Elm (*U. m. variegata*), the leaves of which are silvery striped. *U. effusa* is a continental species with a large spreading head and smooth bark, distinguished also by the long stalks of its flowers and its ciliated fruit.

The American or White Elm (*U. americana*), which abounds in the Mississippi basin, and attains its loftiest stature between 42° and 46° N. lat., is a magnificent tree, sometimes 100 feet in height, the trunk reaching 60 or 70 feet before it separates into branches, and the widely diffused pendulous branches floating gracefully in the air; but the timber is not much esteemed. Slippery Elm (*U. fulva*) is also common in the basin of the Mississippi as far south as 31° N. lat., and in the western parts of Canada. It attains a height of 50 or 60 feet. The wood is more valuable than that of the last species, but much inferior to the English elm. The leaves and bark yield an abundant mucilage, which is bland and demulcent, and esteemed a valuable remedy in catarrh, dysentery, and other complaints. The Wahoo or Winged Elm (*U. alata*) is a small tree, found from 37° N. lat. to Florida, Louisiana, and Arkansas, remarkable for the branches being furnished on two opposite sides with wings of cork. The wood is fine-grained, compact, and heavy. Both the English elm and the Wych elm have been introduced into the United States. *U. chinensis* is a Chinese species of elm,

the leaves of which bear galls used in tanning and dyeing.

The name Spanish Elm is given in the West Indies to a valuable timber-tree also called Bois de Clypre, *Cordia Gerascanthus*, of the natural order Cordiaceæ; also to *Hamelia ventricosa*, of the natural order Rubiaceæ, the timber of which is known to cabinetmakers as Prince-wood.

**Elmalu**, a town of Asia Minor, in the province of Konieh, on the Lycian tableland, 45 miles W. of Adalia. It has manufactures of red leather, dye-works, and a general trade. Pop. 25,000, mainly Greeks and Armenians.

**Elmina**, a British settlement and fortified seaport on the Gold Coast, a few miles W. of Cape Coast Castle. It was first settled by merchants of Dieppe, came into the hands of the Portuguese in 1482, and of the Dutch in 1682, and in 1872 was ceded to the British, who destroyed the native town during the Ashanti war. Pop. 6000.

**Elmira**, capital of Chemung county, New York, on the Chemung River, 149 miles ESE. of Buffalo by rail. It contains a court-house, a state reformatory, and a number of good schools, including the Elmira Female College, and has extensive manufactures of iron rails, railway and other carriages, flour, leather, woollens, boots and shoes, &c. Pop. (1870) 15,863; (1880) 20,541.

**Elmo's Fire**, St., is the popular name of an electric appearance sometimes seen, especially in southern climates during thunder-storms, of a brush or star of light at the tops of masts, spires, or other pointed objects. It is also observed at the tops of trees, on the manes of horses, and occasionally about human heads. It is similar in kind to the luminous glow seen at the point when a lightning-rod is working imperfectly, or when there is any very rapid production of electricity (see ELECTRICITY). In the four years 1884-87 eleven cases of St Elmo's fire were recorded at the Ben Nevis observatory. The phenomenon, as seen at sea, was woven by the Greeks into the myth of Castor and Pollux, and was regarded as of friendly omen. The name of *Elmo* is by many thought to be a corruption of that of Helena, the sister of Castor and Pollux. Others take it to be a corruption of St Erasmus, a Syrian bishop and martyr of the 3d century (Italianised, *Ermo*, *Elmo*). The phenomenon has also been called the fire of St Elias, of St Clara, of St Nicolas, and of Helena, as well as *compositæ* or *compositant* (i.e. *corpus sanctum*) on the Suffolk seaboard.

**Elmshorn**, a town in the Prussian province of Sleswick-Holstein, is situated on a navigable feeder of the Elbe, 20 miles NW. of Hamburg. It has considerable manufactures, especially of boots and shoes, an active trade in grain, a boat-building yard, and some breweries and tanneries. Pop. 8712.

**Elmsley**, PETER, classical scholar, was born in 1773, and educated at Westminster and Christ Church, Oxford, where he graduated B.A. in 1794. He next took orders, and was presented in 1798 to the living of Little Horkeley in Essex, which he held till his death. He lived at various periods of his life at Edinburgh, at St Mary Cray in Kent, and at Oxford, where he was in 1823 appointed principal of St Alban Hall, and Camden professor of Ancient History. Here he died, 8th March 1825. Elmsley contributed to the *Edinburgh and Quarterly* reviews, but is now remembered only by his valuable critical work on Sophocles and Euripides. See *Elmsleiana Critica* (1833).

**El Obeid**. See OBEID (EL).

**Elocution** (Lat., 'speaking out'), the art of effective speaking, more especially of public speaking. It regards solely the utterance or delivery; while the wider art of oratory, of which elocution

is a branch, takes account also of the matter spoken. The art of elocution held a prominent place in ancient education, and in the United States is more carefully cultivated than in Britain.

**Eloge.** When a member of the French Academy dies, it is customary for his successor to deliver an oration, setting forth his merits and services. This is called an *éloge* (Lat. *elogium*, Gr. *eulogia*, 'praise'), and a considerable branch of French literature goes by the name. Interesting and valuable collections are the *éloges* of Fontenelle (2 vols. 1731), and of Cuvier (1819).

**Elohim**, *Elôh*, plural of *Eloah* (only used in poetry; cf. Arab. *Ilâh*, Chald. *Elâh*, Syr. *Alôh*), might, power; in plur., great beings, kings, angels, gods, *Deity*. As a *pluribus excellentia* or *majestatis*, and joined to the singular verb, it denotes, with very rare exceptions, *the One, true God*. Joined to the plural verb, however, it usually means gods in general, whether including the One or not. It is mostly used (in the singular sense) for or together with *Jehovah*; but some portions of the Scriptures employ exclusively either the one term or the other. This circumstance has given rise to endless discussions, and suggested the opinion that Genesis is by different authors (see *BIBLE, JEHOVAH*). It was very probably Peter Lombard who first tried to prove the Trinity out of this plural form—an attempt which, although unanimously and scornfully rejected by almost all scholars, from Calvin, Calixtus, the younger Buxtorf, &c., to our times, was revived by Rudolf Stier.

**Eloi**, or *ÉLIGIUS*, St. Bishop of Noyon and apostle of Flanders (588-658), was originally a goldsmith, and as such became patron of goldsmiths and hammermen.

**Elopement.** See *MARRIAGE, ABDUCTION, GREYNA GREEN*.

**Elopora.** See *BORNEO*.

**El Paso del Norte** (*The Pass of the North*), commonly called *EL PASO*, a town of Mexico, including a line of settlements extending along a narrow valley of 9 or 10 miles in length, on the right bank of the Rio Grande (which forms the boundary between Mexico and the United States), in the Mexican state of Chihuahua. The valley is very fertile, yielding considerable quantities of wine and brandy. The town, 1232 miles NNW. of the city of Mexico by the Mexican National Railway, of which it is the terminus, is wretchedly built, and inhabited chiefly by Indian half-breeds; a large custom-house trade is carried on, however, besides almost equally active smuggling operations. Pop. 6000.—On the opposite bank of the Rio Grande, which is here crossed by a railway bridge, is *El Paso*, capital of *El Paso* county, Texas, through whose custom-house general imports to the value of \$3,531,604, besides precious metals returned at \$10,508,215, passed in the year 1886-87, as against only \$40,909 of exports. Pop. 3500.

**Elphin**, a bishop's see in Roscommon, Ireland, united to Kilmore in 1833.

**Elphinstone**, ADMIRAL. See *KEITH (VISCOUNT)*.

**Elphinstone**, MOUNTSTUART, fourth son of the eleventh Lord Elphinstone, was born in 1779, entered the Bengal civil service in 1795, and was posted to Benares, where he laid the foundation of that love of literature which distinguished him through life. During the operations of 1803 he was attached to Wellesley's staff, and his conspicuous services earned from his general the compliment that he had 'mistaken his profession, and ought to have been a soldier,' from his superiors the appointment to the post of resident at Nagpur. In 1808 he was selected as envoy to Shah Shuja (see

*AFGHANISTAN*), of which the only fruit that remains is his *Account of Caubul* (2d ed. 1841); and in 1810 he became resident at Poona, where, in the Mahratta war of 1817, his military qualifications gained for him the honour of bringing the campaign to an end, and organising the newly-acquired territory. During his governorship of Bombay (1819-27) he founded the present system of administration, and greatly advanced public education. He returned to England in 1829, and declining the governor-generalship of India, lived in comparative retirement until his death, 20th November 1859. Elphinstone ranks next to Wellesley among those most instrumental in raising the fabric of British rule in India after the downfall of the Mahratta power. His well-known *History of India* appeared in 1841 (6th ed. 1874). See his *Life* (1884) by Sir E. Colebrooke, who also edited his *Rise of British Power in the East* (1887); and his *Official Writings*, with Memoir by Forrest (1884).

**Elphinstone**, WILLIAM, a celebrated Scottish prelate, and founder of King's College, Aberdeen, was born in 1431. He was the son of William Elphinstone, a canon of Glasgow, and archdeacon of Terioldale—a natural son, for the marriage of ecclesiastics was then prohibited. Elphinstone studied at the university of Glasgow, where he took his degree of M.A. in 1452, some time later receiving priest's orders. He spent nine years on the Continent, and so highly distinguished himself in the study of law that he was appointed professor in the university of Paris, and afterwards at Orleans. He returned to Scotland, and was made successively official-general of the diocese of Glasgow (1471-72), rector of the university (1474), and official of Lothian in 1478, 'then probably,' says Mr Cosmo Innes (*Sketches of Early Scottish History*, Edin. 1861), 'the second judicial office in the kingdom.' He was made Bishop of Ross in 1481, and of Aberdeen in 1483; was several times engaged in embassies, and for a few months before the death of James III. held the office of chancellor of the kingdom. Under James IV. he was employed on a mission to the Continent, and seems to have been keeper of the Privy Seal from 1492 till his death. He applied himself to the faithful discharge of his episcopal functions, endeavouring to reform the clergy, the service, and the ritual of the church. It appears to have been chiefly through his influence that the first printing-press—that of Chepman and Millar—was established in Scotland. The college of Aberdeen was founded in 1500, and dedicated to St Mary, a name afterwards changed to King's College. Additions to the cathedral and a stone bridge over the Dee were also due to his energy and liberality. The fatal battle of Flodden, 9th September 1513, broke the spirit of Elphinstone, who was never seen to smile after. He died in Edinburgh, 25th October 1514, and was buried before the high altar of the chapel of King's College which he had founded. His *Breviarium Aberdonense*, printed in 1509-10, was reprinted in two volumes quarto at London in 1853.

**Elsass-Lothringen.** See *ALSACE-LORRAINE*.

**Elsinore** (Dan. *Helsingør*), a town and seaport of Denmark, on the island of Zealand, is situated on the western shore of the Sound, and at its narrowest part, 2½ miles nearly due west of Helsingborg in Sweden, and 37 by rail N. of Copenhagen. The town, which has been in recent times considerably improved, consists of one principal street, with several lateral branches. The harbour (enlarged in 1883-84) has 18 to 20 feet of water, and the roadstead outside affords excellent anchorage. Elsinore has considerable trade, and some ship-building. Pop. 8978. The Sound dues were collected here until their abolition in 1857.

Saxo Grammaticus, a famous writer of the 12th century, was born at Elsinore, and here too Shakespeare lays the scene of *Hamlet*. Elsinore was raised to the rank of a town in 1416; it was several times destroyed by the Hanseatic League, and in 1658 was taken by the Swedes, but restored to Denmark two years later. A short distance east of the town is the fortified castle of Kronborg, built in the Dutch Renaissance style by Frederick II. in 1580, while to the north-west of Elsinore stands the royal castle of Marienlyst, now much visited as a seaside resort; it commands an extensive view of the Sound and its islands, its shores, and the towns on them.

**Elssler**, the name of two celebrated dancers, sisters, and natives of Vienna—Therese (1808-78) and Fanny (1810-84). Their first great triumph was at Berlin in 1830; in 1841, after a tour through the capitals of Europe, the two sisters went to America, where they excited unwonted enthusiasm. They retired from the stage in 1851, in which year Therese became the wife of Prince Adalbert of Prussia, and was ennobled by the king of Prussia as Frau von Barnim.

**Elster**, the name of two rivers of Germany, the White and the Black Elster. The White Elster rises at the foot of the Elster Mountains, on the north-western boundary of Bohemia, flows in a northerly direction, and falls into the Saale, above the town of Halle, in Prussian Saxony. Total length, 122 miles. The Black Elster rises in Saxony, south of Elstra, flows north-west, and joins the Elbe 9 miles SE. of Wittenberg, after a course of 112 miles.

**Elstracke**, RENOLD, long classed as one of the earliest native English engravers, was born probably in Belgium towards the end of the 16th century, and flourished in England in the early part of the following century. He worked chiefly for the booksellers, and his engravings, including portraits of the kings of England, of Mary, Queen of Scots, and Darnley, of Whittington, and numerous other notabilities, are much sought after, chiefly from their rarity.

**Elswick**, a township on the western outskirts of Newcastle. Here are located the works of the firm of Sir W. G. Armstrong, Mitchell, & Co. (see ARMSTRONG, LORD), which are among the largest of the kind in Europe. The engineering section of these works dates from 1847; the ordnance-works were founded in 1857. The frontage towards the river is about one mile, the entire area occupied is about 125 acres, and in busy times about 14,000 work-people are employed. Elswick Park, including Elswick Hall, was opened as a recreation ground in 1878. Pop. (1881) 34,642.

**Elton**, a shallow, oval-shaped salt lake of Russia, with a superficial area of 62 sq. m., is situated in the government of Astrakhan, the lat. of its centre being 48° 56' N., and the long. 46° 40' E. In spring the lake has a layer of almost pure salt-crystals, from 2 to 4½ inches thick. The annual yield ranges between 88,000 and 96,000 tons, being about one-seventh of the total salt production of Russia.

**Elton**, CHARLES ISAAC, of Whitestaunton, Somerset, an eminent jurist and ethnologist, was born in 1839, maternal grandson of Sir Charles Abraham Elton (1778-1853), of Clevedon Court, Somerset, poet and translator of Hesiod. He had his education at Cheltenham and Balliol College, Oxford, became Fellow of Queen's College in 1862, was called to the bar at Lincoln's Inn in 1865, and afterwards became Q.C. He was returned to parliament in the Conservative interest for West Somerset at the bye-election in 1884, was defeated for the West or Wellington division of Somersetshire

at the general election of 1885, but again returned at the election the year after. He had already made a reputation as a jurist by his books, *The Tenures of Kent* (1867), *A Treatise on Commons and Waste Lands* (1868), *A Treatise on Copyholds and Customary Tenures of Land* (1874), and *Custom and Tenant Right* (1882), when he placed himself in the front rank of English ethnologists by his *Origins of English History* (1882). Not the least merit of this learned and ably reasoned work is its vindication of the Celtic element in the English race, which had been unduly minimised by the predominant Teutonic school of English history. The dissertation on *Borough English* (q.v.) is a masterpiece of learning and lucidity.

**Elutriation** is the term applied to the process of separating, by means of water, the finer particles of earths and pigments from the heavier portions. The apparatus generally used is a large vat, in which grinding wheels revolve; and the substance to be reduced to powder being placed in the vat along with water, the wheels in revolving not only pulverise the material, but from their motion being communicated to the water the latter is enabled to retain in mechanical suspension the finer particles of the clay, &c. By allowing a stream of water to flow in and out of the vat, the finer particles can be constantly floated away, and the liquid being run into settling vats, the fine powder settles to the bottom, when the water can be run off from the surface. This process is much employed in the manufacture of the materials used in pottery, and in the preparation of pigments.

**Elvan**, or ELVANITE, is the miner's name in the south-west of England for a granular crystalline rock, composed of quartz and orthoclase, which forms veins associated with granite. It occurs as veins not only proceeding from the granite and traversing other rocks, but in the body of the granite itself. It is included by geologists under Quartz-felsite.

**Elvas**, the strongest fortified city of Portugal, in the province of Alentejo, near the Spanish frontier, and 10 miles W. of Badajoz by rail. Standing upon a hill, it is defended by seven large bastions and two isolated forts, and has an arsenal and cannon-foundry. It is a gloomy town and a dirty, yet is supplied with water by a fine aqueduct, carried on three rows of superimposed arches. Its inhabitants (10,471) carry on an active contraband trade with Spain, principally in British manufactured wares, also in wool and wine. The district, which is very fertile, yields oil, wine, fruits, and vegetables. Elvas was made a bishop's see in 1570. In 1580 it was taken by the Spaniards, but they suffered a severe reverse before the town in 1659, and laid siege to it in vain in 1711. It was captured again in 1808 by the French.

**Elves**. See FAIRIES.

**Elwes**, JOHN, M.P., a famous miser, born in 1714, was the son of a successful brewer in Southwark named Meggot. With some good qualities of mind, he was so overcome by the passion of avarice that he would walk miles in the rain to save the hire of a conveyance, would sit for hours in wet clothes to save the expense of a fire, or risk his life to save paying a penny at a turnpike. His only indulgence seems to have been hunting. He died at Marcham, Berkshire, 26th November 1789, leaving property worth half a million.

**Ely**, a city of Cambridgeshire, crowns a low eminence on the left bank of the Ouse, amid the fen-land, 16 miles NNE. of Cambridge, and 30 SE. of Peterborough. Here, in 673, St Etheldreda (q.v.) founded a mixed monastery, which, burned in 870 by the Danes, was refounded in 970 as a Bene-

dictine abbey by Ethelwold, Bishop of Winchester. That abbey a century later became Hereward's 'camp of refuge,' until, in 1071, after a long and obstinate defence, Abbot Thurstan had to surrender to the Conqueror. In 1083 the first Norman abbot laid the foundation of the present church, which was made a cathedral in 1109, and which, as we see it to-day, is one of the most glorious shines in Christendom. A cruciform structure, 537 feet long by 179 feet across the great transepts, it offers examples of all styles of Gothic, from early Norman to late Perpendicular, and is a growth of more than four centuries. There is the Early English 'galilee' or western porch (c. 1200); the western tower, 225 feet high, Transition Norman and Decorated (1174-1382); the south-west transept, now the baptistery; the late Norman nave (1150-89), 208 by 78 feet, with modern painted ceiling; the great transepts (1083-1170), Norman, with Perpendicular insertions; the richly sculptured choir (1234-1533), Early English, Decorated, and Perpendicular; the Decorated north-eastern Lady Chapel (1321-49); and at the crossing, the exquisite Decorated 'octagon' and lantern (1322-42), built by Alan de Walsingham on the fall of the great central tower. This, 'the only Gothic dome in existence,' rises to a height of 170 feet. Since 1845 the whole pile has been ably restored, mainly under the supervision of the late Sir G. G. Scott.

Ely Cathedral—Octagon.

It wants the north-west transept, the cloisters, and the chapter-house; but the 13th century Guesten Hall is now the deanery, and the 'Ely Porta,' or great gateway (1380), houses a grammar-school founded by Henry VIII. in 1541. The Bishop's Palace is a fine brick Tudor building. Among the bishops, nearly sixty in number, have been Langham, Bouchier, and Morton (archbishops of Canterbury), Arundel (archbishop of York), and Androwes, Wren, Patrick, and Harold Browne. Of great laymen also, Ely has its memories, from Canute to Cromwell, who lived here 1636-40. There is a weekly market; and oil, earthenware, and clay-pipes are manufactured. Pop. (1861) 6176; (1891)

8017.—The 'Isle' of Ely, for which see the articles CAMBRIDGESHIRE and BEDFORD LEVEL, contains also March and Wisbeach, and is 355 sq. m. in area, with 63,328 inhabitants. Till 1837 it was a county palatine.

See Benthams' *History of Ely Cathedral* (2d ed. 1812); J. H. Clement's *History of Ely* (1868); Canon D. J. Stewart's *Architectural History of Ely Cathedral* (1868); Dean Merivale's *Bissexcentenary Festival of St Etheldreda* (1874); and Murray's *Eastern Cathedrals* (new ed. 1881).

**Elyot, SIR THOMAS**, author of *The Governour*, seems to have been born not later than 1490, in Wiltshire (not Suffolk), and not to have studied at either Oxford or Cambridge. In 1511 he became clerk of assize on the western circuit, in 1523 clerk of the king's council. In a letter addressed to Cromwell he complains that he performed the duties of this clerkship by the space of six years and a half 'withoute fee, withoute reward more than the ordinarie, and that which more greiveth me, withoute thank of the king.' Later letters reveal him to us much impoverished by lawsuits, and begging for a share in the confiscated property of the monasteries. In 1531-32, as ambassador to Charles V., he visited the Low Countries and Germany, having orders to procure, if possible, the arrest of Tyndale. In 1535 he went on a second embassy to the emperor, whom he seems to have followed from Barcelona to Tunis and Naples. Member for Cambridge in 1542, he died at Carlton, Cambridgeshire, 20th March 1546. His chief work, *The Boke named the Governour*, devised by Sir Thomas Elyot, Knight, was published in 1531. It may be described as the earliest treatise on moral philosophy in the English language, the author's principal object being 'to instruct men in such vertues as shall be expedient for them which shall have authoritie in a weale publike.' An elaborate tenth edition appeared in two vols. in 1880, with an excellent life, notes, and glossary by Mr H. S. Croft. Elyot's twelve other works include *Of the Knowledge which maketh a Wise Man* (1533); *Pasquill the Playme* (1533); *Isocrates' Doctrinal of Princes* (1534); *Picus de Mirandola's Rules of a Christian Lyffe* (1534); *The Castel of Helth* (1534); *The Bankette of Sapience* (1534); *Bibliotheca* (1538), the first Latin-English dictionary; *The Image of Governance* (1540); *Defence of Good Women* (1545); and *Preservative against Deth* (1545). These books went through edition after edition in their author's lifetime, and they have now become among the rarest treasures of the bibliomania.

**Elysium** (Gr. *elysion*), a place in the infernal regions of the ancient classical mythology, where the souls of the good dwell after death. In the *Odyssey*, Homer describes it as a place where the souls of the departed lived in ease and abundance among innocent pleasures, enjoying a mild and wholesome air. In the *Iliad*, however, he gives a sombre view of the state of the departed souls. Achilles, though in Elysium, is made to envy the life of the meanest hind on earth. By succeeding poets the bliss of Elysium is drawn in much brighter colours. Besides the amenity and various delights of the place, diverse employments are found for the inhabitants, according to the ruling passion of each while on earth. The Elysian plains were supposed by some writers to be in mid-air, by others in the sun, by others in the centre of the earth, next to Tartarus, and by others in the Islands of the Blest. See HADES.

**Elytra**, or WING-COVERS, a term applied to the fore-wings of beetles (Coleoptera), which are modified to form more or less tough and hard coverings for the hind pair. The term Hemelytra is applied to the short, firm fore-wings of Earwigs (q.v.) (Dermaptera). See INSECTS, BEETLES.

**Elze**, **FRIEDRICH KARL**, Shakespearian scholar, was born at Dessau, May 22, 1821, studied at Leipzig and Berlin, devoting especial attention to English literature, and afterwards continued his studies in England and Scotland. In 1875 he was appointed to the newly-established chair of English Language and Literature at Halle, and here he died January 21, 1889. His early publications include a collection of English songs, and *Atlantis* (1853-54), a journal dealing with England and America. In editions of *Hamlet*, Chapman's *Alphonsus*, and Rowley's *When you see me, you know me*—the last two edited for the first time—he endeavoured to apply the strict method of classical philology to a modern language. An English translation of his biography of Byron appeared in 1872, and of his *Essays on Shakespeare* in 1874; these last are selected from the *Shakespeare-Jahrbuch*, which he edited for the German Shakespeare Society from 1868 to 1879. Other works are his *William Shakespeare* (Halle, 1876; Eng. trans. 1888) and his *Notes on Elizabethan Dramatists* (Halle, 2 vols. 1880-84). Elze was a laborious student and sagacious critic rather than a mere antiquary or collector, and, moreover, was sane beyond the measure of great Shakespearians.

**Elzevir**, the name of a celebrated family of printers at Amsterdam, Leyden, and other places in Holland, whose beautiful editions were chiefly published between the years 1592 and 1681. During this period, covering scarcely a century, M. Willems has catalogued no fewer than 1600 works, all such as were doubtful having been rigorously excluded. The difficulty of determining what are genuine Elzevirs depends partly on there having been a good number of printers who bore the name, and on their having had three or four principal places of business. But above all, they were booksellers as well as printers, hence many works were attributed to them which were hardly published, and certainly not printed, by them; while imitations were constantly being made, and they themselves issued many books under pseudonyms, or other printers' or publishers' names. Louis, the first to make the name famous, is said to have been born at Louvain about the year 1540, and, driven by the religious commotions of the time, to have settled as a bookbinder and bookseller in Leyden, where he died about 1617. The first work issued by him bears the title *Drusii Ebraicorum Questionum ac Responsionum Libri Duo*, and the date 1583. The first work, however, really published by him at his own risk, was a *Entropius* by P. Merula (1592). From this time till his death he published over a hundred books, his typographical mark (first used in 1595) being the arms of the United Provinces—an eagle on a column, holding in its talons a sheaf of seven arrows, with the inscription *Concordia res parva crescit*.

Five out of Louis's seven sons continued to carry on their father's business. Their names were Matthias, Louis, Aegidius (Giles), Jodocus (Joost), and Bonaventura. The last, in conjunction with his nephew Abraham Elzevir (a son of Matthias), prepared the smaller editions of the Latin classics, in 12mo and 16mo, which are still valued for their beauty and correctness. Among the finest examples of these are the *Livy*, *Tacitus*, *Pliny*, and *Cæsar* (1634-36). Equally celebrated were their 24mo editions of French historical and political authors under the name of the *Petites Républiques*, and their 12mo French and Italian classics. The handiness and cheapness of these duodecimos, of which a volume of no less than 500 pages was sold for but one florin, found approbation from all but a few pedants who believed there could be no scholarship save in folios. The printing was long supervised

by Abraham, while Bonaventura managed the publication and sale; the learned David Heinsius wrote the Latin introductions and dedications to many of the books. In 1625 they acquired the printing business established at Leyden by Isaac, the second son of Matthias, who had become printer to the university there. His typographical mark was an elm surrounded by a vine-branch bearing clusters of fruit, below which stands a solitary figure, with the motto *Non solus*. M. Willems has proved that the Elzevir type designs were due to Cornelius van Dyck. The two heads of the house died near each other in 1652, and their successors were Joannes Elzevir, Abraham's son, and Daniel, Bonaventura's son, who nobly maintained the traditions of the press. Their finest works were an *Imitatio* without date, and a psalter of 1653. In 1654 Daniel settled at Amsterdam, where he united with Louis, eldest son of Joost, who had already settled there in 1638, and distinguished himself by his editions of the works of Cartesius. The masterpieces of the new partnership were the *Corpus Juris* in folio (1663) and the French Bible (1669). Their typographical mark was a Minerva with the agis, an owl, and olive-branch, and the motto *Ne extra oleas*. The last representatives of the house were Peter, grandson of Joost, who flourished at Utrecht from 1670 to 1672, and Abraham, son of the first Abraham, who was university printer at Leyden from 1681 to 1712. The Elzevirs were clever men of business, and were none too liberal to many of the scholars on whose labours they rose to wealth. So valuable are some productions of Elzevir's press, by reason of rarity or otherwise, that an unimportant cookery-book called the *Pâtissier* sold in 1877 for 3250 francs. See Pieter, *Annales de l'Imprimerie Elzevirienne* (Leip. 1852); Willems, *Les Elzevier* (Brussels, 1880); Andrew Lang, *Books and Bookmen* (1886); and Goldsmid's *Complete Catalogue* (Edin. 1888).

**Emanation**, in Theology and Philosophy, is an important word in various systems which considered all things as *emanating* or flowing from a Supreme Principle. According to these, the origin of things is only an overflowing of the divine fullness—an outstreaming of the light from the necessity of its nature, and not any conscious exercise of will on the part of God. What is thus given off as a copy from original perfection departs more and more from its source, and gradually degenerates, which was thought to account for the origin of evil. This doctrine pervades ancient Egyptian and Indian mythology, Neoplatonism (q.v.), and Christian Gnosticism (q.v.).

**Emancipation**, in the Roman law, was the act by which the *Patria Potestas* (q.v.), or paternal authority, was dissolved in the lifetime of the father. It took place in the form of a sale (*mancipatio*) by the father of the son to a third party, who manumitted him. The Twelve Tables required that this ceremony should be gone through three times, and it was only after the third sale that the son became *sui juris*, under his own law. In general, the son was at last resold to the father, who manumitted him, and thus acquired the rights of a Patron (q.v.), which would otherwise have belonged to the alien purchaser who finally manumitted him. In the case of daughters and grandchildren one sale was sufficient. In the law of Scotland, emancipation is called *Forisfamiliation*. See also SLAVERY, SERF, CATHOLIC EMANCIPATION.

**Emanuel I.**, king of Portugal, styled THE GREAT, or THE FORTUNATE, was born 31st May 1469, and succeeded John II. in 1495. His reign has been termed the golden age of Portugal. He prepared the code of laws which bears his name, and made his court a centre of chivalry, of art, and

of science. Vasco da Gama's voyage round the Cape of Good Hope, Cabral's discovery of Brazil, and the expeditions under Albuquerque and others that extended the Portuguese possessions as far as the Moluccas, were all commissioned and encouraged by Emanuel. Through his exertions Portugal became the first naval power of Europe and the centre of the commerce of the world. He died 13th December 1521.

**Emarginate.** See LEAVES.

**Emba** (Russ. *Yomba*), a river of the Asiatic Russian government of Orenburg, in the Kirghiz territory, rises at the western base of the Mugdshar Mountains, and flowing south-west, enters the Caspian Sea after a course of about 450 miles.

**Embalming** (so named from the balm or balsam often employed), the art of preserving the body after death, invented by the Egyptians, whose prepared bodies are known by the name of mummies, and are called in the hieroglyphs *sahn*, and by St Augustine *gubbaroa*. This art seems to have derived its origin from the idea that the preservation of the body was necessary for the return of the soul to the human form after it had completed its cycle of existence of three or ten thousand years. Sanitary reasons may also have influenced the ancient Egyptians; and the legend of Osiris, whose body, destroyed by Typhon, was found by Isis, and embalmed by his son Anubis, gave a religious sanction to the rite. The art appears as old as 4000 B.C. at least, for the bodies of Cheops, Mycerinus, and others of the age of the 4th dynasty, were embalmed. One of the earliest

Egyptian Mummy.

embalments recorded in literature is that of the patriarch Jacob; and the body of Joseph was thus prepared, and transported out of Egypt. The process has been described by Herodotus and Diodorus; but their accounts are only partially confirmed by an examination of the mummies. A scribe marked with a reed-pen a line on the left side beneath the ribs, down which line the *paraschistes*, or ripper of the district (an officer of low class), made a deep incision with a rude knife of stone; he was then pelted with stones, and pursued with curses. The *taricheutes*, or salter, next proceeded to remove the entrails and lungs, with the exception of the heart and kidneys, while a colleague extracted the brain through the nose. The body was ready for the salts and spices necessary for its preservation, the quality of which depended upon the sum to be expended. When Herodotus visited Egypt, three methods prevailed: the first, accessible only to the wealthy, consisted in passing peculiar drugs through the nostrils into the cavities of the skull, rinsing the belly in palm-vine, and filling it with myrrh, cassia, and other substances, and stitching up the incision in the left flank. The mummy was then pickled in natron for seventy days, and then washed and elaborately bandaged up in rolls of linen, cemented by gums, and set upright in a wooden coffin against the walls of the house or tomb. This process cost a silver talent, perhaps equal to £725 of our money. A cheaper process, by means of an injection of cedar-oil, cost a *mina*, relatively worth about £243. The poorer classes washed the corpse in myrrh, and salted it for seventy days. When thus prepared, and covered with a pictorial representation of the deceased, attired as a labourer in the world to come, and

duly labelled as a 'justified Osiris,' the mummy was placed in a costly coffin (see SARCOPHAGUS) ready for sepulture, but was frequently kept some time before being buried—often at home—and even produced at festive entertainments, to recall to the guests the transient lot of humanity. All classes were embalmed, even malefactors; but various methods were employed besides those mentioned by Herodotus. Some mummies are found merely dried in the sand; others salted by natron, or soaked in bitumen (Jew's pitch) with or without the flank incision, having the brains removed through the eyes or base of the cranium, with the viscera returned into the body, placed upon it, or deposited in jars in shapes of the genii of the dead, the skin partially gilded, the flank incision covered with a tin plate, the fingers cased in silver, the eyes removed and replaced. So effectual were some of these processes that after 2000 or 3000 years the soles of the feet are still elastic and soft to the touch. The sacred animals were also mummied, but by simpler processes than men. It has been computed that since the practice began in 4000 B.C., down to 700 A.D., when it practically ceased, probably as many as 730,000,000 bodies were embalmed in Egypt; of which many millions are yet concealed. Important finds are made from time to time, as in 1881, when upwards of thirty mummies of potentates, including that of Rameses II., were discovered together at Deir-el-Bahari. Mummies, it may be observed in passing, were used in the 15th and 16th centuries of the Christian era for drugs and other medical purposes, and as nostrums against diseases, and a peculiar brown colour, used as the background of pictures, was obtained from the bitumen.

Other less successful means of embalming were used by nations of antiquity. The Persians employed wax; the Assyrians, honey; the Jews, aloes and spices; Alexander the Great was preserved in wax and honey, and some Roman bodies have been found thus embalmed. The Gnanches, or ancient inhabitants of the Canary Isles, used an elaborate process like the Egyptian; and desiccated bodies, preserved by atmospheric or other circumstances for centuries, have been found in France, Sicily, England, and America, especially in Central America and Peru. In Burma the bodies of priests are stuffed with spices and honey and coated with wax and gold-leaf. The art of embalming was probably never wholly lost in Europe; De Bils, Swammerdam, Clauderus, Gooch, Bell, and others attained great success in the art; and a mode of embalming by incisions all over the body is detailed by Penicher. Ruysch, and after him William Hunter, injected essential oils through the principal arteries into the body. Boudet embalmed the bodies with camphor, balsam of Peru, Jew's pitch, tan, and salt. The discovery of Chausser of the preservative power of corrosive sublimate, by which animal matter becomes rigid, hard, and grayish, introduced a new means of embalming by Beclard and Larrey; but owing to the desiccation, the features do not retain their shape. The discovery of the preservative power of a mixture of equal parts of acetate and chloride of alumina, or of sulphate of alumina, by Gannal in 1834, and of

Mummy Case of Queen Almes Nofretari: Height 9 feet. (From Maspero's *L'archéologie Egyptienne*.)

that of arsenic by Tranchini, and of pyroxilie spirits by Babington and Rees in 1839, and of the antiseptic nature of chloride of zine, have led to the application of these salts to the embalming or preparation of bodies required to be preserved for a limited time. The latest method, by injection of a fluid into the arteries, is described by Dr B. W. Richardson, who has himself embalmed fifty bodies. The process is very common in the United States.

See Pettigrew, *History of Mummies* (1834); Gannal, *Traité d'Embaumement* (1838); Magnus, *Das Einbalsamiren der Leichen* (1839); Richardson, *The Asclepiad* (1888); and the article HEART-BURIAL.

**Embankments**, in Engineering, are masses of earth, rock, or other materials artificially formed, and rising above the natural surface of the ground. They are chiefly formed either (1) to carry railways, common roads, canals, &c. over depressions of the country; or (2) for hydraulic purposes, such as the formation of reservoirs for storing water, or as defences against the overflowing of rivers and the encroachments of the sea or of lakes.

In the formation of canals, railways, and other roads, embankment and *excavation* go hand in hand, and, under the name of Earthwork, form—especially in modern times, and since the development of the railway-system—a vast branch of industry, giving employment to many thousands of labourers, known in England as ‘navvies.’ See CANAL, DYKE, ROAD, RAILWAY, RESERVOIR.

**Embargo** (from the Spanish *embargar*, ‘to imbar,’ ‘to arrest’) is a temporary order from the Admiralty to prevent the arrival or departure of ships. It may apply to vessels and goods, or to specified goods only; it may be general or special; it may apply to the entering only, to the departure only, or to both entering and departure of ships from particular ports; and lastly, although issued by the Admiralty in England, it would be equally an embargo if issued by any other competent authority. Such embargoes are generally connected in some way or other with a state of war between two countries.

**Embassy**, in its stricter sense, is a mission presided over by an ambassador, as distinguished from a mission or legation intrusted to an envoy, or other inferior diplomatic minister. See AMBASSADOR.

**Embattled.** See CRENELLED.

**Ember Days**, in the Roman and Anglican churches, are three days appointed four times in the year to be observed as days of fasting and abstinence; being the Wednesday, Friday, and Saturday after the first Sunday in Lent, after the feast of Pentecost, after the 14th September, and after the 13th December. The name is probably derived from the Saxon *ymb*, ‘about,’ and *ryne*, a ‘course’ or ‘running,’ and applied to these fasts because they came round at certain set seasons in the year. In the breviary and missal these days, as recurring in each quarter of the year, are called *quatuor tempora* (the canonists’ *jejunia quatuor temporum*, or ‘fasts of the four seasons’); and another derivation would make the term only a corruption of this title, perhaps through the German form, *quaterember*. The ember days date from an early period in the church’s history, and were introduced into England by Augustine. Originally they were only in part devoted to beseeching the grace of the Holy Ghost, as periods when ministers were admitted to holy orders; but it is to this purpose that the ember days are now particularly devoted, Roman Catholic clergy being ordained only on the Saturdays of the ember weeks, while the whole church fasts and prays, and a generally similar usage prevailing in the Church of England, which has appointed special prayers for use at these seasons.

**Emberiza.** See BUNTING.

**Embezzlement**, the felonious appropriation by clerks, servants, or others in a position of trust, of goods, money, or other chattels intrusted to their care, or received in the course of their duty, on account of their employers. It is essential to the crime of embezzlement that the article taken should not have been in the actual or constructive possession of the employer; for if it were, the offence would amount to Larceny (q.v.). Embezzlement is not a felony at common law; hence, persons guilty of this crime sometimes escaped punishment. In consequence of a flagrant instance of this immunity, the Act 39 Geo. III. chap. 85, was passed, whereby embezzlement was made a felony. This act has been repealed, but the law has since been fixed by subsequent enactments, and is now included in the Act 24 and 25 Vict. chap. 96.

*Embezzlement by clerks or servants* is punishable by penal servitude or imprisonment. If the offender be a male under sixteen, he may also be ordered to be privately whipped, at the discretion of the judge. Questions of much nicety often arose as to whether the facts proved constituted the crime of embezzlement or that of larceny; but this distinction has ceased to be of any importance under recent acts, whereby it is made competent, on an indictment for embezzlement, to convict a man of larceny, and *vice versa*. And hence, whichever of the two offences is charged against the servant, if the evidence shows he committed the other offence, then he may be found guilty of that other offence, and punished accordingly.

*Embezzlement by bankers, brokers, factors, and other agents* is now regulated by the statute cited above. Almost every conceivable species of fraudulent misappropriation by bankers and others is now a punishable offence. In particular, by the latter statute, embezzlement by a Bailee (see BAILMENT) is now indictable. A shopkeeper, for example, appropriating goods intrusted for repair, may be tried and convicted (see also FRAUD).

*Embezzlement by bankrupts*, or rather the pawning or disposing within four months before the bankruptcy of goods or any kind of property obtained on credit, is punishable by two years’ imprisonment. See BANKRUPTCY.

*Embezzlement of letters and newspapers* by servants of the Post-office is also made highly penal by 7 Will. IV. and 1 Vict. chap. 36. The embezzlement of newspapers is punishable by fine or imprisonment; for embezzling a letter the extreme penalty is penal servitude for seven years, or (if the letter contain money or valuables) for life.

*Embezzlement of the Queen’s stores* is punishable by penal servitude for fourteen years. In regard to this species of embezzlement, summary authority was given to comptrollers and other officers named, on proof of embezzlement of government stores below the value of twenty shillings, to fine the offenders to the amount of double the value of the article taken.

The American law is, in principle, the same as the English, but it seems that a person indicted for larceny cannot be convicted of embezzlement, or *vice versa*. Embezzlement of national property is punishable by the law of the United States; other forms of embezzlement and fraudulent breach of trust are dealt with by the laws of the several states.

In Scotland, the crime of embezzlement, or breach of trust, is punishable at common law. The distinction between this crime and that of theft is substantially the same as between embezzlement and larceny in England. In both countries, the criterion relied upon to distinguish these crimes is

the question of possession by the owner; but in Scotland the tendency of the decisions of late years has been to regard the appropriation of articles intrusted for a temporary purpose as amounting to theft. In this respect the law of Scotland agrees with that of England in regard to embezzlement by a bailee.

**Emblem.** By many writers on this subject symbols and emblems are regarded as almost convertible terms, and hence the former is often used in a sense synonymous with the latter. But, according to Claude Mignault, the famous commentator on the emblems of Andreas Alciatus, in his tract 'Concerning Symbols, Coats of Arms, and Emblems,' there is a clear distinction between emblems and symbols, which, as he says, 'many persons rashly and ignorantly confound together.' This writer maintains that 'the force of the emblem depends upon the symbol, but they differ as man and animal;' his meaning being, that as all men are animals, but all animals are not men, so all emblems are symbols, but all symbols are not emblems. Hence he argues the two possess affinity but not identity, they have no absolute convertibility of the one for the other (H. Green, *Shakespeare and the Emblem Writers*, 1-3). But for all practical purposes there is little difference between the two terms. Of the many definitions given of emblem may be quoted that of Francis Quarles, who says 'an emblem is but a silent parable;' and Cotgrave describes it as 'a picture and short posse, expressing some particular conceit.' For printer's Emblems, see BOOK.

**Emblements**, growing crops of cereal and vegetable productions raised by the labour of the cultivator. Fruits of trees growing on the land, and grass, are not emblements. See LANDLORD AND TENANT, LEASE.

**Emblica**, a genus of Euphorbiaceæ. *E. officinalis* is an Indian tree whose acid, astringent fruit (*Apyrobolani emblicæ*) is a source of tannin.

**Embolism.** See ARTERIES (DISEASES OF).

**Embossing.** When a raised pattern is produced by blows or pressure upon sheet-metal, leather, cloth, paper, gutta-percha, &c., it is said to be embossed. A vase or dish formed of thin sheet-metal is sometimes decorated in relief by beating it up from the inner or under side. This operation is called beating up, bossing, or *repoussé*, and may be considered as an example of embossing by hand. A somewhat similar result is obtained by the use of a die and counter-die worked in a screw-press or by a falling weight, but this is usually called stamping (see DIE-SINKING, and STAMPING OF METALS). The term embossing is not applicable to decoration in relief produced by carving or chiselling, or by casting. Writing-paper and card are embossed with a steel die, the counter-die being formed of millboard or leather, faced with gutta-percha. The paper or card is damped, and a fly-press or lever-press is generally used.

Leather is embossed in several ways. For book-covers, even in the case of patterns in comparatively bold relief, like those used for photographic albums, brass dies and millboard counter-dies are used along with a lever or screw-press (see BOOK-BINDING). When for other purposes the ornament is to be in high relief, moulds or reverses of metal or wood are required, or separate ornaments of wood or papier-mâché, fixed to a board, may be used. The leather is first softened with water, and then pressed with tools of various kinds into the moulds, or spread over the fixed ornaments, and worked into all their cavities with the fingers and a pointed tool. The hollows of the more deeply relieved portions are filled in with paper pulp and other substances.

At the present time, imitations of embossed leather for wall-decoration are very much in fashion. These are made of canvas, leather, paper, and various other substances. Even so fine a material as satin is embossed for this purpose. Embossed linen canvas made of a durable nature is coming much into use for decorative purposes. It is manufactured by passing the damped canvas over a metal roller, heated internally with steam, upon which the pattern is cut or engraved in intaglio. As the web passes over the roller, brushes or pads are applied to press the canvas into the indentations. By means of additional rollers, a backing of paper is pasted on, and when the whole is dry it is stiff and retains its shape. Japanese wall-papers, which are embossed in a somewhat similar manner to the linen canvas just described, but by the use of flat instead of cylindrical moulds, are now a good deal used in England. The patterns are often beautiful, the paper is strong, and the surface is made durable by coatings of oil and lacquer. Embossed canvas, paper, and leather for wall-decoration are commonly coloured and gilt.

Calicoes and other textiles are embossed by means of deeply engraved metal cylinders fitted into calender frames. The counter-roller is covered with felt, which yields sufficiently to allow the fabric to be pressed into the hollows of the die-cylinder. Sometimes the pattern is on two cylinders, being sunk on the one and raised on the other, after the plan of a die and its counterpart.

There is a method of embossing wood by saturating it with water, in which state a red-hot cast-iron mould is forcibly pressed upon it. Generally the wood is re-wetted, the mould re-heated, and the pressure applied several times before a complete impression of the mould is obtained. A curious mode of embossing wood was invented about 1830 by J. Straker. The design is drawn upon the surface to be thus decorated, and all the parts intended to be in relief are then carefully depressed by a blunt tool. The wood is next planed down to the level of the depressed portions. On being steeped in water, these will rise to their former level, forming an embossed pattern ready, when the wood is dry, to receive the finishing-touches of the carver. By a process recently invented in America, veneers of wood are embossed with metal dies. See DIE-SINKING.

The process of etching ornamental patterns with hydrofluoric acid on plate-glass, for the panels of lobby-doors, &c., is called 'embossing.'

**Embowed**, the heraldic term for anything bent like a bow—as, for example, the arm of a man.

**Embracery**, in the law of England, the offence of influencing jurors by corrupt means to deliver a partial verdict; the offence is punishable by fine and imprisonment.

**Embrasures**, in Fortification, are openings in the parapets, flanks of bastions, and other parts of the defence-works, through which cannon are pointed. See FORTIFICATION.

**Embroidery** (Fr. *broderie*) is the art of producing ornamental patterns by means of needle-work on textile fabrics, leather, and other materials which can be sewed over. The art is closely allied to tapestry-work, which is in fact intermediate between embroidery and weaving. The essential distinction is that, while embroidery is always worked upon an already woven texture, the basis of tapestry is a series of parallel strings or cords forming a kind of warp, to which the various coloured yarns required for the pattern form the weft; and thus the cloth-making and the building-up of the pattern are one operation.

The art of embroidery, arising out of the universal craving for ornamentation, may be said

to be coeval and co-extensive with the use of clothing and furniture. It is practised with interesting and characteristic variations by the rudest tribes; and it is held in high esteem by the most gifted and highly cultured of nations. That it was early practised in oriental nations we have abundant evidence. It is most probable that the coat of many colours bestowed by Jacob on his favourite Joseph was a triumph of needlework, as looms at that period were capable of producing simple striped and checkered patterns only. Remains of Egyptian embroidery, as ancient as the days of Jacob, exist still; and of the art as practised by the early Egyptians Sir J. Gardner Wilkinson remarks, 'the many dresses painted on the monuments of the 18th dynasty show that the most varied patterns were used by the Egyptians more than 3000 years ago, as they were at a later period by the Babylonians, who became noted for their needlework.' The knowledge and skill acquired in Egypt by the Israelites enabled them to embroider the elaborate priestly robes and tabernacle furniture, 'the cherubim of cunning work,' 'the pomegranates of blue and of purple and of scarlet,' and the other needlework enumerated in the Book of Exodus. The 'goodly Babylonish garment' secreted by Achan at Jericho was probably an example of Babylonian skill in needlework; and indeed the frequency of allusion to embroidery in Scripture, as well as in the works of classical writers from Homer downward, testifies to the high appreciation and importance of the art in early times. Then, as in later ages, the triumphs of the art were reserved for priestly robes and for temple adornment.

The knowledge of artistic embroidery came to Europe from the nations of the East, where the art had its early home, and where it still is most largely appreciated and practised. To the Greeks and Romans it came from Phrygia, whence at Rome the embroiderer was known as *phrygius*, and gold embroidered work was called *auriphrygium*, from which we have the ecclesiastical English term *orpheury*. It was in medieval times that the embroiderer's art attained its greatest perfection in Europe; and it is remarkable that the most highly appreciated examples of work were of English origin. The finest existing specimen of medieval embroidery—the Syon Cope, now in South Kensington Museum—is English work of the 13th century. It is richly charged with scriptural subjects, and carries the armorial bearings of several of the most illustrious English families of the period. In historical interest, however, this cope falls far behind the Bayeux Tapestry (q.v.). Under the influence of the Oxford movement, and along with a revival in church architecture and glass-painting, has come a great revival of church embroidery as applied to altar-cloths, vestments, banners, &c.

Practically, embroidery is divided into two distinct classes of work: (1) that which embraces all kinds of artistic needlework done by the hand; and (2) the manufacturing industry which includes all embroidery done by machinery, and also such hand-needlework as is done on the large scale by following patterns mechanically impressed on the fabric to be ornamented.

In art embroidery the materials employed are fine coloured worsted yarns called crewels, tapestry wools, embroidery silks, gold and silver threads, spangles, and plates or discs of metal. There may also be used portions of feathers, the elytra of beetles, pearls, and precious stones; but these find their place principally in oriental embroideries. The textile basis may be any cloth, but the fabrics principally used are stout makes of linen, silks, satins, velvets, and flannels. Small work is done

without any special mounting, but for elaborate designs the fabric is fitted and tightly stretched on a frame. The variety of embroidery stitches is considerable, and must vary with the nature of the outline to be formed and the texture or subject to be imitated; and colours have, of course, to be carefully varied according to the necessities of the design when a coloured pattern is being worked. The principal stitches are the stem stitch, the satin stitch, the knotted stitch, the button-hole or blanket stitch, the chain or tambour stitch, the feather stitch, and the ension or Berlin work stitch, all of which may be best learned from practical manuals. In frame-work, 'couching' is largely employed, which consists in laying lengths of thread on the surface, and securing them by stitches through the cloth brought up at various points, variety of effect being obtained by the different disposition of these securing stitches. A distinct class of embroidery consists of appliqué or cut work, in which designs of different materials and colours are cut out and sewed down on the surface of the fabric to be ornamented. Inlaid appliqué consists of cutting precisely the same pattern out of two different fabrics, and inserting the one into the cut space in the other.

In its purely mechanical side, the embroidery trade embraces several distinct sections, of which may be enumerated (1) white embroidery, known also as Swiss or Scotch sewed work, for which work the muslin or other fabric is printed with a pattern made up of holes of different dimensions, which are either cut or punched out, and their edges sewn over with a button-hole stitch; (2) embroidery in gold, silver, and coloured silks, for official costumes, civil and military, badges, &c.; (3) embroidery in crewels, or other coloured wools, coloured silks, &c., mostly done for furniture decoration, such as borders of tablecovers, &c.; and (4) there may be included ornamental braiding with braids of various colours, principally for ladies' costumes. To a great extent these various kinds of embroidery can be worked by one or other of the machines which have been devised for embroidering. The first successful embroidery machine was that invented by M. Josué Heilmann, of Millhansen, patented in England in 1829. With Heilmann's machine, or the modifications of it which have since been introduced, one person can guide from 80 to 140 needles working simultaneously, and producing so many repeats of the same design. The details of the construction of the machine are complex, but the principle of its action may be easily understood. The needles, with their eyes in the middle, are pointed at each end, so that they may pass from both sides of the work without being turned. Each needle is worked by two pairs of artificial fingers or pincers, a pair on each side of the work, and these grasp and push the needle through from one side of the work to the other. A carriage or frame connected with each series of fingers does the work of the human arm, by carrying the fingers to a distance corresponding to the whole length of the thread. The frame then returns to exactly its original place, and the needles are again passed through to the opposite set of fingers, which act in like manner. Were the work which is mounted in a frame to remain stationary, the needles would thus pass merely backwards and forwards through the same hole. But the frame is mounted to move in every direction, and according to its motion stitches varying in length and in direction are made corresponding to the lines of the design. The motion of the frame is governed by a pantagraph machine (see PANTAGRAPH), the free end of which, moving over an enlarged copy of the design, moves the frame at each successive stitch into the position required for the production of

the various repeats of the pattern. Embroidery patterns, in a variety of knotted, tambour, and other stitches, and ornamental braiding, are now very largely done by means of the Bonnaz machine, the invention of M. Antoine Bonnaz, first patented in Britain in 1868. This apparatus is in appearance and construction like the ordinary sewing-machine, but in place of a needle, it is furnished with a hooked looper which passes down through the work and brings the thread up from below, looped around it to make a knotted stitch on plain for the ordinary tambour stitch. It is further provided with a universal feed-motion, so that with the utmost ease the work can be guided to follow the lines of the most intricate and sharp-turning pattern. A modification of this machine, invented by M. E. Cornely, is in extensive use for ornamental braiding.

The following works may be consulted: Caulfield and Seward, *Dictionary of Needlework* (1881); E. Glaister, *Needlework* ('Art at Home' series, 1880); Gay et Dupont Auberville, *Catalogue des Broderies au Musée des Arts Décoratifs* (Paris, 1880); L. Higgin, *Handbook of Embroidery*, edited by Lady Marian Alford (1879); *Drawings of Ancient Embroidery*, by Mrs Mary Barber (1881); Lefebvre's *Embroidery and Lace* (Eng. trans. 1888).

**Embrun**, a fortified town in the French department of Hautes Alpes, crowns a rock-platform on the right bank of the Durance, and at the base of Mont St Guillaume (8344 feet), 23 miles E. of Gap by rail. It looks better from without than within; but its cathedral has a lofty Romanesque tower. Pop. 3812. Embrun occupies the site of *Ebrodunum*, capital of the Caturiges, and an important Roman station. It was the seat of a bishopric from 374 to 1802.

**Embryo** (Gr.), a term usually restricted (a) to the unborn young animal, or (b) to the rudimentary young plant, especially when within the seed. The term *fetus* is equivalent to embryo, but is restricted to mammalian development. The term *larva* is also applied to a young animal which is more or less markedly different from the adult form. See EMBRYOLOGY, REPRODUCTION, SEED.

**Embryology** is that department of biology which reads the development of the individual organism. It is a succession of studies in anatomy and physiology which, when read into unity, give the history of the organism from its earliest individual appearance on to that vague point when it may be said to exhibit all the main features of adult life. The investigation necessarily takes two forms: a description of the structure of successive stages (*morphological*), and an analysis of the vital processes associated with each step (*physiological*). Nor is any embryological investigation complete which does not link the everyday development of individuals with the historical evolution of the race.

*History.*—Although the development of the chick, so much studied in embryological laboratories to-day, was watched 2000 years ago in Greece, it was only in the scientific renaissance of the 17th century that observation began to grow strong enough to wrestle with conjecture. Harvey, who towered as a strong genius above his contemporaries, and saw much farther, sought in 1651 to establish two main propositions: (1) that every animal was produced from an ovum—*ovum esse primordium commune omnibus animalibus*; and (2) that the organs arose by new formation (*epigenesis*), not from the mere expansion of some invisible preformation. These valuable generalisations were not, however, accepted, and even observations like those of Malpighi seemed for the time to tell against Harvey's prevision. The time was past for absolutely fanciful theories, and yet the domi-

nant doctrine which persisted even into the 19th century was mystical enough. The germ, whether egg or seed, was believed to be a miniature model of the adult. 'Preformed' in all transparency, the organism lay *in nuce* in the germ, only requiring to be 'unfolded.' Just like a bud which hides within its hull the floral organs of the future, so was every germ. 'There is no becoming,' Haller said; 'no part of the body is made from another; all are created at once.' But the germ was more than a marvellous bud-like miniature of the adult; it included all future generations. That germ lay within germ, in ever smaller miniature, after the fashion of an infinite juggler's box, was the logical corollary of the theory of preformation and unfolding. One of the controversies of the time was whether ovum or sperm was the more important. The ovists asserted the claims of the ovum, which only required to be awakened by the spermatozoon to begin its unfolding. The animalculists, on the other hand, maintained that the male element contained the preformed germ, and that the ovum was merely for its preliminary nutriment.

All this was virtually shattered by Wolff (1759), who reasserted Harvey's epigenesis, and showed that the germ consisted of almost structureless material, and that the process of development was a gradual organisation. Yet Wolff's work had not the effect of entirely demolishing preformationist conceptions. They lingered on, and had this much truth in them that the germs are indeed potential, though not miniature, organisms. To some extent Wolff reacted too far against the mystics in his emphasis on the simplicity of the germ, so that a correction was necessary when the cellular character of the reproductive elements was realised about a hundred years later. The observation of structural progress was slow in gaining self-confidence, for it was not till 1817 that Pander took up Wolff's work virtually where he left it. He was immediately reinforced and soon left behind by Von Baer, whose results laid a firm foundation for modern embryology. Since the establishment of the Cell-theory (see CELL) in 1838-39, and the associated researches which showed that the organism starts from a fusion of two sex-cells, and that development consists in the division of the fertilised ovum and differentiation of the results, progress has been both sure and rapid. The more modern demonstration of the fact of evolution has afforded a fresh impulse by its interpretation of the present as the literal child of the past.

*The egg-cell or ovum* is in all organisms the starting-point of the embryo, but development can rarely begin till this female element is supplemented by the male cell or spermatozoon. These sex-cells are liberated units of the parent-organism, but in most cases they stand in marked contrast to the great congeries of cells which form the 'body.' All the component units of the organism are indeed lineal descendants of a fertilised ovum, but the 'body'-cells become greatly changed into muscle, nerve, skeleton, and the like, while the reproductive cells retain with more or less intactness the characters of the original parent germ. It is this fact which makes the reproduction of like by like possible.

The unicellular animals or Protozoa, having obviously no 'body,' are directly comparable to the sex-cells of higher animals. The 'body' is the addition which makes the difference. In a few Protozoa, however, the results of the division of a unit remain associated together, and a loose colony of cells arises. Such a Protozoon behaves like an ovum or like a primitive male-cell in any of the higher animals. The loose colony may be very unstable, and may soon resolve itself into its

component units, exactly as the primitive male-cell, which has divided into a clump of spermatozoa, breaks up and sets these active units free. But the colony may be more stable and retain its continuity (like a segmented ovum), thus bridging the gulf between unicellular and multicellular organisms. In such cases certain cells are set apart as reproductive, and eventually set adrift to start a fresh colony. This is the beginning of the differentiation of special reproductive cells. At first these were probably all alike and able to develop of themselves, but in a manner which does not concern us here (see SEX) they became differentiated as male and female elements, mutually dependent and complementary.

The ovum has all the essential characters of an ordinary animal cell. The cell-substance consists of Protoplasm (q.v.) and of material ascending to or descending from that climax. As in other cases, the cell-substance may be traversed by a network,—one of the intricacies which modern microscopic technique has revealed. Like other cells, the ovum includes a central differentiation or nucleus, technically called the germinal vesicle. This exhibits the essential nuclear elements in the form of rods, bands, or network, and other minute features described in the article CELL. The nucleus plays a most important part in the history of the ovum, and is believed to be the bearer of the hereditary characteristics.

As to the precise origin of the ova, it is enough here to state that in sponges they are simply well-fed cells in the general substance (middle stratum) of the sponge; that in Coelenterates they may originate from outer or from inner layer; while in other animals they are almost always associated with the middle layer of the body, and as we ascend are more and more restricted to a distinct region or to a definite organ—the ovary.

The very young ovum is often at least like an Amœba (q.v.), and in Hydra (q.v.) this character persists. The first chapter in its history is one of nutrition and growth. This often occurs at the expense of neighbour cells, and the ovum may be the successful survivor of a clump. In other cases the nutriment, for immediate or future use, may be derived from the vascular fluid of the animal, or from special glands, which are sometimes simply degenerate portions of an originally larger ovary. The capital of nutriment thus derived is distinguished as the yolk. It varies greatly in quantity and disposition, and has great influence in determining the precise form which the future division of the ovum will take. It may be small in quantity and uniformly diffused through the cell, as in mammalian ova; there may be a larger quantity, which sinks to the lower part, as in frog spawn; there may be a very large amount, which quite dwarfs the genuine living matter, as in birds' eggs; or there may be a central accumulation, as in crustaceans and insects. The egg is very generally surrounded with some membrane, sheath, or shell, made by itself, or contributed by surrounding cells, or the product of special glands. In such envelopes there is often a special aperture (micropyle) through which alone the spermatozoon can enter. Hard shells like those of birds' eggs must obviously be formed after fertilisation has taken place.

*The Male-cell or Spermatozoon.*—In the unicellular organisms, among which we find the key to all beginnings, two cells, unable apparently to live independently, unite, and thus make a fresh start. In such cases the two units are usually similar in appearance, though doubtless different in chemical state. Sometimes, however, a small active cell unites with a larger and more passive

neighbour, and here we find the first hint of the profound difference between the sexes—a difference of which the contrast between spermatozoon and ovum is literally a concentrated expression.

The spermatozoon is a true cell, though the nuclear portion often predominates over the cell-substance. It is one of the smallest animal cells,

Fig. 1.—Organisms:

a, ovum showing egg membrane, granules, and germinal vesicle; b, spermatozoon; c, hermaphrodite gland of snail, with ova and sperms; d, amoeboid ovum; e, coalescence of sperm-cell and egg-cell.

as the ovum is one of the largest; it is highly active, while the ovum is peculiarly passive; it rarely bears any nutritive material, while the ovum is very generally weighted with yolk. In its minute size, active locomotor energy, and persistent vitality, the sperm-cell resembles a flagellate Monad among Protozoa, while the ovum is strictly comparable to an Amœba or to one of the yet more passive or encysted forms. In most animals the spermatozoon exhibits three distinct parts: (a) the 'head,' or essential portion, consisting almost wholly of nucleus; (b) the mobile 'tail' of contractile protoplasm which drives the 'head' along; and (c) a small middle portion connecting the head and tail.

In its origin the male-cell resembles the ovum, and the two cells are of course the physiological complements of one another. In history, however, the ovum is strictly comparable not to the sperm, but to the cell which divided to give rise to the sperms. The primitive male-cell, or mother-sperm-cell, is the homologue of the ovum. Just as the latter divides in segmentation, so the mother-sperm-cell divides, and the divisions exhibited in what is technically called spermatogenesis are closely parallel to the various modes of segmentation exhibited by ova. The mother-sperm-cell segments, but the results have no coherence; they go asunder as spermatozoa. Thus, though all cells may be said to rank as equals, the sperm-cell has a longer history behind it than the ovum. The differences both in form and history express the great differences in chemical constitution which are summed up in the words male and female.

*Maturation of the Ovum.*—The egg-cell having attained its definite size or limit of growth, usually exhibits a somewhat enigmatical phenomenon known as the extrusion of polar globules. In the great majority of cases it buds off two tiny cells, by a true process of cell-division, in which the nucleus plays its usual orderly part. This extrusion is probably universal, but has not yet been observed in bird or reptile eggs. The polar cells come to nothing, though they may linger for a while in the precincts of the ovum. Their expulsion usually takes place before fertilisation has even begun, but sometimes is subsequent to the entrance of the spermatozoon into the ovum. The result of the twofold budding is that the mass of the nuclear elements is reduced by three-fourths, though their number appears to remain constant. In many parthenogenetic ova, which develop without fertilisation, Weismann has recently shown that only one polar globule is formed, and this he believes to be constant, and essentially associated with parthenogenesis.

The import of the process is much disputed.

Cells do indeed usually divide at the limit of growth (see CELL), but the division here is peculiarly unequal so far as cell-substance is concerned. The marked inequality suggests the theory proposed by Minot, Balfour, and Van Beneden, that the polar globules are male extrusions from the predominantly female egg-cell. The retention of one in parthenogenetic ova is supposed to be what makes independent development possible. The retained polar globule replaces the otherwise necessary sperm. Bütschli looks at the matter rather historically than physiologically, and interprets this premature division of the ovum as the survival of an ancient habit which the mother-sperm-cell still retains. The polar cells are thus rudimentary or abortive female germs. This, however, hardly explains why they should so constantly occur. Weismann supposes the two polar globules to be very different from one another: the first extrudes a nuclear substance which was only useful while the egg was a-making; the second gets rid of half of the essential germ-plasma, the bearer of hereditary characteristics, all in order to make room

Fig. 2.—Development of Sperms; maturation and fertilisation of Ova (diagrammatic):

1-4, Division of a mother-sperm-cell or primitive-male-cell into a ball of spermatozoa which breaks up; a-f, maturation and fertilisation of ovum; a, anisobol young ovum; b, later stage; c, budding off of a first polar cell; d, budding off of a second; e, spermatozoan round ovum, one entering; f, male and female nuclei about to fuse on completion of fertilisation.

for the addition of a corresponding quantity by the spermatozoan. Parthenogenetic ova only give off the first, and retain all their germ-plasma. Thus they are as able to start in development as fertilised ova which exhibit the circuitous process of first giving half of their germ-plasma away and then getting a similar quantity back from another source. There is no proof that the two extrusions are different in character, and Weismann's theory seems to invest ova with a prevision of the benefits of fertilisation. The simplest view is that the ovum divides at the limit of growth, that the inequality of division expresses an opposition between what is extruded and what is retained, and that this means the getting rid of some waste or male elements. In the differentiation of the male elements both among plants and animals, a parallel but reverse antithesis is often demonstrable.

**Fertilisation.**—The 'ovists' thought that the ovum was all-important, and only required the sperm's wakening touch to unfold its preformed model. The 'animalculists' were equally certain that the spermatozoan was all-important, and only required to be fed by the ovum. Even after the mutual dependence of the sex-elements had been recognised, the opinion prevailed that contact of the two was unessential, and that by an *aura seminalis* fertilisation was possible. In 1677 Hamann and Leeuwenhoek first distinctly saw spermatozoa; in 1780 Spallanzani showed by artificial fertilisation that the eggs must come into contact with the seminal fluid; in 1843 Martin Barry observed the spermatozoan in union with the ovum of the rabbit; in 1846 Kölliker proved the cellular origin and nucleated character of the male elements; and in

1872-75 Bütschli and Anerbach observed two nuclei in fertilised eggs. The dates of these representative discoveries show how gradually the result has been reached that the essence of fertilisation is the intimate union of a male and female cell.

It is needless to cite the numerous investigators who have made the following statements possible: (1) Only one male element really unites with the egg-cell. By a sudden change after the entrance of one sperm the ovum usually ceases to be receptive. The entrance of more than one occasionally occurs, but the result is pathological. (2) The union is very intimate; the nuclei are at least as important as the protoplasm, and according to most authorities much more so. (3) The two nuclei are attracted or drawn to one another, and fuse intimately to form a single nucleus of double origin. (4) Intimate as the union is, its orderliness is not less conspicuous; half of the result is still traceable to the male and half to the female.

While these are the demonstrable structural facts, what the union means is another matter. Some compare the action of the sperm to a ferment, others to stimulating waste products, while Weismann virtually denies sex differences altogether, and maintains that the union is a mere quantitative addition of the amount of germ-plasma lost in extruding the second polar globule. That the spermatozoan furnishes half of the architectural nuclear substance and thereby half of the hereditary characteristics is certain, that it also affords a chemical stimulus to division it is difficult to doubt. In single-celled animals fertilisation is essential to the continued vitality of the species; in all cases the intimate mingling of sex-elements, different in constitution and past experience, secures both an average constancy and minor variations.

**Segmentation.**—Soon after the essential act of fertilisation has been accomplished in the intimate union of the nuclei, the egg begins to divide. What physical and chemical attractions and repulsions operate in this process we do not know. It is certain that the nuclear elements, which play a very important part throughout, have what we cannot but call a strong individuality of behaviour. It is certain too that the cell-substance plays an important part, and that it is not merely passive material with which the nucleus operates. Recent observers, led by Van Beneden, have elucidated something of the marvellous interaction between nuclei and cell-substance. It would seem that there is an intracellular muscular system, that from certain centres in the protoplasm strands radiate which moor themselves to the nuclear elements and move them about. It has been further established that the double nucleus of the fertilised ovum is accurately composed half of female and half of male elements. When the egg divides into two, the nucleus of each daughter-cell is again half male and half female, and it is probable that this exact dualism persists yet further.

The different ways in which ova divide depend mainly upon the quantity and disposition of the passive yolk-material. (1) When there is very little nutritive capital, and that uniformly diffused, the whole ovum divides, vertically and horizontally, till a sphere of approximately equal cells is formed. This total segmentation occurs for instance in the ova of sponge, starfish, lancelet, and mammal. (2) In the ova of the frog, where the actual process of division may be most conveniently watched, there is more yolk, which has chiefly sunk to the lower hemisphere of the egg. Division is still total, but after a few segmentations it will be seen that the upper hemisphere cells are dividing more rapidly and are becoming markedly smaller than those in the lower part. The segmentation is total but unequal. (3) In the ova of birds and reptiles

and many fishes there is a large quantity of yolk, and the formative substance lies like a drop on the upper surface of the nutrient mass. Division is

Fig. 3.  
Relation of Yolk to division of Ovum (diagrammatic):

- |                             |                             |
|-----------------------------|-----------------------------|
| A, little and diffuse yolk. | A', total equal division.   |
| B, more yolk at lower pole. | B', total unequal division. |
| C, central yolk.            | C', peripheral division.    |
| D, much yolk.               | D', partial division.       |

restricted to the formative protoplasm, and thus the segmentation is conspicuously partial. (4) In the ova of crustaceans, insects, and their allies, the yolk usually accumulates in the centre of the ovum as a more passive, nutritive core, surrounded by the active, formative protoplasm. The latter divides, and forms a sphere or ellipsoid of cells around the less markedly divided yolk. In *Peripatus*—the survivor of ancestral insects—the whole ovum segments, but the cells are not for a while defined off from one another, so that the result looks like a giant Protozoon with numerous nuclei. Hints of this are seen in other cases.

**Morula and Gastrula.**—The result of segmentation is a ball of cells, differing according to the above described modes of division. When a wide cavity has been left, between the cells as they multiplied, a hollow sphere is formed, technically called a *blastosphere*; if no such conspicuous 'segmentation cavity' has been left the result is an almost solid mulberry-like ball of cells—a *morula*. When the division is partial, mainly confined to an area of formative protoplasm lying upon a nutritive mass, the result is a disc of cells which by and by spreads round the yolk. Such a segmented area is generally known as the *blastoderm*. (See D', fig. 3.)

The next decisive chapter is one of infolding, or the formation of a *gastrula*. In the simplest cases one hemisphere of a hollow ball of cells is dimpled or invaginated into the other. More accurately, the one hemisphere sinks into and becomes surrounded by the other. The sphere becomes a two-layered sack or *gastrula*, with an opening technically called the *blastopore*. In many other cases—e.g. fishes, reptiles, and birds—owing to the yolk, complete invagination is not possible. An infolding still occurs, but it is no longer conspicuous, and the gastrula-stage is thus disguised. It must also be noted that the two-layered condition may arise by *arrangement* of the cells, without there being any process that can be called invagination. Thus, in

Fig. 5.  
Gastrula:  
Showing ecto-  
derm, ciliated  
endoderm,  
blastopore,  
and central  
cavity.

the oval ciliated embryo or *planula* of most Hydrozoa, the two layers have been frequently observed to arise by a process of internal differentiation, known as *delamination*.

**The Germinal Layers.**—Even in a simple colony

of cells like a *Volvox* all the units do not remain alike. Inside cells are in different conditions from outside cells, and division of labour with consequent difference of structure is bound to occur. So again, in the ball of cells into which the ovum divides, the one hemisphere with heavier material is usually different from the upper hemisphere, which is specifically lighter and less encumbered with reserve material. Even in the morula or blastosphere differentiation has begun.

But we have just seen that by the folding of one hemisphere into the other, or in other ways, a gastrula often more or less modified arises. The embryo thereby attains definitely differentiated layers—outer and inner. The preformationists spoke of development as an unfolding; we now insist on an infolding. The layered character of the embryo was early recognised by Wolff, and yet more clearly by Pander and Von Baer, but its fundamental import can hardly be said to have been realised till Huxley in 1849 compared the outer and inner cell-layers of Coelenterates (hydroids, jelly-fish, &c.) to the outer and inner layers which embryologists had begun to demonstrate in development. Soon afterwards Allman gave to the outer and inner layers of Coelenterates the names *ectoderm* and *endoderm*, which are now universally used for the outer and inner layers of every embryo. The results reached by Huxley and Haeckel, Kovalevsky and Ray Lankester, and many others, have made it certain that the formation of these two germinal layers is constant in animals, that they are exactly comparable throughout the series, and that with few exceptions they give rise to precisely the same adult structures.

In sponges and Coelenterates only two genuine layers of cells are developed. A middle stratum, seen in faint suggestion in the common *Hydra*, may indeed appear between outer and inner layers, and may be of the greatest importance in the structure of the animal, but embryologists are not inclined to allow this middle stratum—the so-called *mesoglea*—to rank as a distinct layer beside the other two.

In higher animals, however, there is a definite middle layer or *mesoderm* between the other two. Its history involves much greater difficulty than that of the ectoderm and endoderm; it seems as if it might arise in some half-dozen different ways. One common mode of origin has been emphasised by the brothers Hertwig in what they call the 'Coelome-theory.' The inner layer arises by an infolding of the outer, and a primitive gut-cavity (*archenteron*) thus results. Now begins an out-folding. From the gut-cavity two sacks (*coelome-pockets*) grow out, one on either side, insinuating themselves between the first two layers. The cavities of the sacks form the future body-cavity of the animal; the outer and inner walls form the corresponding two divisions of the mesoderm. However this middle layer arises, it finally exhibits an inner and an outer division, so that the Hertwigs speak of *four* germinal layers. The outer (parietal or somatic) portion of the mesoderm clings to the external body-wall, forming muscles and the like; the inner (visceral or splanchnic) portion cleaves to the internal organs.

**Origin of Organs.**—With few exceptions, the same organs and structures arise from the same layers—e.g. the nervous system from the ectoderm, the lining of the mid-gut from the endoderm. (a) The *ectoderm* or *epiblast* gives origin to outer skin or epidermis, external skeleton, superficial glands, sense-organs, nervous system, the infoldings at both ends of the gut, and probably to the primitive excretory (segmental) duct. (b) The *endoderm* or *hypoblast* forms the lining of the mid-gut, and necessarily, too, of outgrowths from it, such as the lungs and various glands. In verte-

brates it also gives rise to that important skeletal axis—the notochord—which always precedes the ‘backbone.’ (c) The *mesoderm* or *mesoblast* gives rise to all the rest. That is to say, the under-skin, the muscles, the connective tissue, the internal skeleton, the lining of the body-cavity, the heart and the blood, and the like are all mesodermic. The reproductive organs, though to some extent structures by themselves, also arise, in the great majority of cases, in connection with the mesoderm. It must be noted, further, that while the main part of a structure is referable to one of the three layers, the entire structure is very often composite. Thus, the eye of vertebrates mainly arises as an outgrowth from the brain, but some of the less essential parts are furnished by the mesoderm. The outgrowths from the mid-gut are in origin endodermic, but they too are always aided by the middle layer.

*Physiological Embryology.*—The immense progress of embryology within recent years has been almost wholly morphological. Of the physiological conditions of development we know relatively little. The later stages of embryonic life in higher animals have been studied by Preyer and others with much success, but this is but the threshold of investigation. A few luminous results as to the architectural conditions are due to the courage of His and Rauber, who have followed the earlier suggestions of Pander and Lotze. The task, which is involved in stupendous difficulties, has been continued in the experimental investigations of O. Hertwig, Fol, Pflüger, Born, Roux, Schultze, Gerlach, and others. Observations as to the actual dynamics of cell-division, such, for instance, as those of Van Beneden and Boveri, are beginning to appear; while the title of a recent work by Berthold—*Protoplasmic Mechanics*—shows how the biologist persistently seeks the aid of the student of physics in order to explain the architecture of the living organism. ‘To think that heredity will build organic beings without mechanical means’ is, according to His, ‘a piece of unscientific mysticism,’ while Pflüger insists on the conception of development as ‘an organic crystallisation.’ The laws of growth, which express how each fertilised egg-cell must divide, and how the resulting units must arrange themselves first in layers and thereafter into organs, must be expressed in terms of physical and chemical conditions. But this is the task of the future.

*Generalisations.*—(1) *The Ovum-theory.*—In all cases of ordinary sexual reproduction among plants or animals the offspring develops from a fertilised egg-cell. This is the ovum-theory prophesied by Harvey in 1651, again almost realised by Wolff in 1759, but only demonstrated about a hundred years later when the organism was at length analysed into its component cells (see CELL). The fact that every plant or animal begins at the beginning again, at the level of the Protozoa or single-celled organisms, Agassiz does not hesitate to call one of the greatest discoveries in the natural sciences in modern times.

(2) *The Gastræa-theory.*—The simplest animals are single cells; these occasionally form loose colonies or balls of cells; next come sack-like two-layered organisms, such as the simplest sponges. These are the first three grades among living animals, but they also correspond to the first three chapters in the life-history of each organism. The single cell (the ovum), the ball of cells (the morula or blastosphere), the sack of cells in two layers (the gastrula), we have seen to be the first three stages in development. As this gastrula-stage always occurs, though sometimes disguised by the yolk, in the life-history of animals, Haeckel justly emphasised it as the individual’s recapitulation of an ancestral state. The simplest, stable, many-celled animal he believed to be like a gastrula (see fig. 5),

and he called this hypothetical ancestor of all higher animals a gastræa. A few living animals are still almost at this level; all animals pass through it in

Fig. 6.

The First Stages in Development (not drawn to scale):

1, fertilised ovum; 2, ball of cells; 3, the same still more divided, or in section; 4, the gastrula (except in F); A, sponge, coral, earthworm, or starfish; B, crayfish, or other arthropod; C, river snail, or other mollusc; D, lancelet, tunicate, &c.; E, frog, or other amphibian; F, rabbit, or other mammal; s.c., segmentation cavity; g, gastrula invagination; z.r., zona radiata, or porous envelope. Darkly shaded cells are endoderm, lighter are ectoderm, dots are yolk granules.

their gastrula-stage. The gastrula is a recapitulation of the ancestral gastræa. Rival conceptions of what the first stable, many-celled animal was like have been since proposed, but the gastræa-theory still holds the field.

(3) *The Fact of Recapitulation.*—The gastræa-theory is only a special case of a more general proposition—that the individual recapitulates the history of its kind. That the past lives in the present, or that we individually retrace, for instance in our intellectual development, the paths made by our ancestors, is a familiar idea which it is one of the charms of embryology to realise in the life-history of each organism. At an early date Von Baer expressed this in his law, that structural progress or differentiation in development was from a general to a special type. ‘In its earliest stage,’ he said, ‘every organism has the greatest number of characters in common with all other organisms in their earliest stages; at each successive stage the class of embryos which it resembles is narrowed.’ In the life-history of a mammal it is possible to trace how the germ at first lingers as it were among the Protozoa; how it divides and passes quickly through the transitional ‘ball of cells’ stage; how the embryo undergoes its first great differentiation, like all other multicellular animals, in becoming a two-layered gastrula, taking its place beside the ancestral Metazoa; how it by-and-by acquires some of the characters of a young worm, and then of a very simple backboneed animal, like a primitive

fish; how with increasing complexity it ranks with reptilian embryos; and lastly, how the fœtus acquires mammalian features, vague and general at the outset, but gradually becoming like those of nearly related forms. Von Baer himself confessed, as every embryologist would do, that with three embryos of higher Vertebrates at the same stage before him, he could not, without close examination, tell one from the other. The accompanying

Fig. 7.—Embryos of fowl (a), dog (b), and man (c).  
(After Haeckel.)

figure of the embryos of a bird, a mammal, and the human species clearly illustrates this close resemblance in early life.

Spencer expressed the progress from simple to complex, from general to special, as a differentiation from homogeneous to heterogeneous, in which the individual history runs parallel to that of the race. The most luminous reading of the fundamental fact is that of Haeckel. The individual development is a recapitulation of the historic evolution of the race. A curve symbolising the turns and twists in the life-history of one of the higher Vertebrates, for instance, is seen to be a reflection of the great bends and branches of the genealogical tree which expresses the historic lineage. The development of the individual microcosm is a summary—often a shorthand summary—of the evolution of the macrocosm of the race. Most pithily, though most technically, he sums up his 'fundamental biogenetic law' in the words 'Ontogeny recapitulates phylogeny.' The fact is very vividly illustrated in many of the more patent life-histories, such as those of crustaceans, insects, and amphibians, where the hatched young follow the rails laid down by their respective ancestors (see AMPHIBIA, CATEPILLAR, CRUSTACEA). Parker happily compares watching development—in which he is one of the modern masters—to reading a palimpsest; below the superficial script there are older and ruder characters, and below these more primitive still. Two cautions must be emphasised. The development is often shortened in its path; circuitous twists, in what we believe to have been the historic course, are skipped by the individual; the momentous steps, however, are always paralleled in the two histories. The individual development may be said to follow the main line of progress, but does not go off into side-lines. Thus the resemblance is between embryos. The embryo bird is hardly like a reptile, but it is always in its development like an embryo reptile. Nor must it be imagined that this fact of recapitulation exactly explains itself. That the present is child of the past does indeed shed great light on the individual's recapitulation of ancestral stages, but the metaphors are apt to suggest that the developing organism has somehow a feeling for history, or that the hand of the past is literally upon it as it grows. It is necessary to get beyond mere metaphors of unconscious memory and the like, and to realise that the same internal conditions which in the long past led to certain momentous changes are still really present doing the same for the individual. The fundamental problem is to elucidate the chemical

and physical conditions which represent the living hand of the past upon the development of the present, or to understand how the living matter of the embryo is at each stage both the material and the architect of its upbuilding.

(4) *Continuity of Germinal Protoplasm.*—In flowering plants there is a conspicuous contrast between the reproductive system and the general 'body.' In all organisms this antithesis is fundamental, and the recognition of the fact has shed much light upon the problems of development and heredity. In the simplest animals a portion of the cell is separated off to start a new individual; and as this is virtually continuous with the parent the reproduction of like by like is natural and necessary. In a few animals (some worm-types, crustaceans, insects, &c.), when the ovum has multiplied to a limited extent, by the usual process of division, certain of its descendants, as yet very like the original ovum, are set apart to form the reproductive cells of the offspring, and take no share in building up the 'body.' The germ-cells of the offspring, thus early insulated, are in a real sense continuous with the parental ovum; they retain some of the living capital intact, continue the protoplasmic tradition unaltered, and when themselves liberated will naturally do what the original germ-cells did. Thus the reproduction of like by like becomes more intelligible, and we reach the conception of a continuous necklace-like chain of immortal germ-cells from which the mortal bodies of successive generations are budded off. This conception has been more or less clearly suggested by numerous naturalists—Owen, Haeckel, Jäger, Brooks, Galton, Nussbaum, and others, but has been elaborated by Weismann in his theory of the continuity of the 'germ-plasma.' A continuous chain of germ-cells is only demonstrable in a few cases; often they become distinct only at a relatively late stage in the development of the offspring. Therefore Weismann insists not on a continuity of germ-cells from those of the parent to those of the offspring, but only on a continuity of 'germ-plasma.' 'In each development a portion of the specific "germ-plasma" which the parental ovum contains is not used up in the formation of the offspring, but is reserved unchanged for the formation of the germ-cells of the following generation.' The germ-plasma which keeps up the continuity has its seat in the nucleus, is a substance of definite chemical and special molecular constitution, has an extreme power of persistence and enormous powers of growth. The general idea is simple enough—an offspring starts with a capital of living matter which is virtually the same as that from which its parents started. Therefore the results are in a general way the same, and the constancy of the species is sustained. How this is modified by variations is not here relevant.

**Emden**, the chief commercial town in the Prussian province of Hanover, is situated a little below the embouchure of the Ems into Dollart Bay, 77 miles WNW. of Bremen by rail. Emden, which strikingly resembles a Dutch town, is surrounded by walls and moats, is well built, has spacious and well-paved streets, with several lofty

antique houses in the Dutch style, and is intersected by numerous canals, which are crossed by about thirty bridges. A canal runs south from the town to Dollart Bay, a distance of about two miles; but it is navigable at high-water only, and then by vessels of not more than 14 feet draught. The harbour accommodation has been improved in connection with the making of the canal from the Ems (q.v.) to the Jade. The finest building is the town-hall (built in 1574-76), containing a library and a curious collection of ancient arms and armour. Emden has a large shipping trade, especially in corn, cattle, butter, cheese, and bricks, and several manufactures; the principal industry, however, is shipbuilding. Several vessels leave this port every year for the herring-fishery. Pop. (1875) 12,874; (1885) 14,020. Emden belonged originally to East Friesland, and after various vicissitudes was erected a free imperial town under the protection of Holland in 1595, and remained so until 1744, when it passed to Prussia. After belonging successively to Holland, France, and Hanover, it again became Prussian in 1866.

**Emerald** (Span. *esmeralda*, Fr. *émeraude*, Ger. *smaragd*, Gr. *smaragdos*), a mineral generally regarded by mineralogists as merely another variety of the same species with the Beryl (q.v.), with which it essentially agrees in composition, crystallisation, &c., differing in scarcely anything but colour. The emerald, which, as a gem, is very highly esteemed, owes its value chiefly to its extremely beautiful velvety green colour. It is composed of about 67-68 per cent. of silica, 15-18 of alumina, 12-14 of glucina, and minute proportions of sesquioxide of chromium, magnesia, and carbonate of lime. Its colour is ascribed chiefly to the oxide of chromium which it contains. Its specific gravity is 2.70-2.76. In hardness it is rather inferior to topaz. The localities in which the emerald is found are very few. The finest have long been brought from Colombia (q.v.), where they are obtained from veins traversing clay-slate, hornblende slate, and granite; and valuable stones also come from the Upper Orinoco, in Venezuela. Stones of inferior quality are found in Europe, imbedded in mica-schist, in the Henbach Valley, in Salzburg. They also occur in the Urals; and some old mines in Upper Egypt have been found to yield them. This gem, known from very early times, was highly prized by the ancients. Pliny states that when Lucullus landed at Alexandria, Ptolemy offered him an emerald set in gold, with his portrait engraven on it. Many wrought emeralds have been found in the ruins of Thebes. Nero, who was near-sighted, looked at the combats of gladiators through an eye-glass of emerald, and concave eye-glasses of emerald seem to have been particularly esteemed among the ancients. As a precious stone, the emerald is rarely without flaw. Its value also depends much on its colour. A very perfect emerald of six carats has been sold for £1000. It appears not improbable that emeralds have been found in the East, in localities not at present known, but the name Emerald or Oriental Emerald is often given to a very rare, beautiful, and precious green variety of Sapphire (q.v.).

**EMERALD COPPER** is a beautiful and very rare emerald-green crystallised mineral, also called Diopside, found first and chiefly in limestone in the hill of Altyn-Tübe (Altai Mountains), and also obtained in the Urals and the South American Cordilleras. It is composed of about 39 parts silica, 50 protoxide of copper, and 11 water.

**Emer'itus** (Lat.), a term applied originally to a Roman soldier who had served out his time, and been discharged on something equivalent to our half-pay. It is now commonly employed to designate

certain functionaries, such as professors, who have been honourably relieved from the duties of their office, on account of infirmity or long service, and who are usually granted a retiring allowance.

**Emerson, RALPH WALDO**, poet and essayist, born in Boston, United States of America, May 25, 1803; died in Concord, Massachusetts, April 27, 1882. He came of what his own people would call the best New England stock, namely, from a long line of educated and respected ministers. His father was settled over a Boston congregation: an able preacher and an accomplished man of letters. His mother was a woman of high qualities and dignified bearing; his aunt, Mary Moody Emerson, who influenced him very strongly, was a strikingly original and a very cultivated woman. He was the third of seven children; two of his brothers, Edward and Charles, were distinguished for ability, but both died before middle age. His birthplace was within a few minutes' walk of that of 'the great Bostonian,' Benjamin Franklin. His father died when he was six years old, leaving his family in a straitened condition. At eight years old he entered the public grammar-school, and soon afterwards the Latin school. At the age of ten or eleven he was turning Virgil into English heroic verse, was fond of reading history, loved the study of Greek, and was given to frequent rhyming. He thinks the idle books under the bench at the Latin school were as profitable to him as the regular studies. One of his early schoolmates remembered him as 'a spiritual-looking boy in blue nankeens,' whom he loved when he looked upon him, he thought him 'so angelic and remarkable.'

Emerson did not take a very high rank in his college class, that which graduated at Harvard in 1821. He took a second prize, however, for an essay in English, and was chosen class poet after several others had declined. His college career had nothing of the singular brilliancy which characterised that of his brothers Edward and Charles. After graduating he kept school in different places, at the same time studying divinity under the direction of Dr Channing, and attending some of the lectures given at the Harvard Divinity School, the chief Unitarian theological seminary. He was grave, gentle, dignified as a teacher, never punishing except by words. He used to give the boys selections for reading—something from Plutarch's *Lives*, for instance—to carry home with them. In 1826 he was 'approved to preach' by the Middlesex Association of Ministers, and after preaching in several pulpits—at the south, where he was obliged to go for his health, at New Bedford, at Northampton—he was, on the 11th of March 1829, settled as colleague with the Rev. Henry Ware, minister of the Second Church in Boston. In September of the same year he was married to Miss Ellen Louisa Tucker, who died, without leaving any children, in 1832. In this same year he preached a sermon in which he announced certain views with regard to the Lord's Supper which were disapproved by the larger part of his congregation. This sermon is the only one of his ever printed. In consequence of the difference of opinion between himself and his parishioners, he found it impossible to continue in the relation which had been harmonious and happy, and thus, with the most friendly feelings on both sides, he left the pulpit of the Second Church, and found himself obliged to make a beginning in a new career.

In 1833 he made a first visit to Europe, of which he has given a brief account in the work entitled *English Traits*. On his return he preached in different pulpits, and began devoting himself to delivering lectures and writing essays. His first

Company.

subjects were 'Water' and 'Relation of Man to the Globe'—hardly such as we should have expected from the spiritual philosopher and poet, his acquaintance with the physical sciences being apparently very limited. But he wished to make good the loss of his salary, and lectured on branches of knowledge in which he knew he could interest the public. After a short experience he ventured on subjects more congenial to his past studies and habits of thought—Michael Angelo, Milton, Luther, George Fox, and Edmund Burke. In 1834 Emerson fixed his residence at Concord, a pleasant farming town in Middlesex county, Massachusetts, famous for having been the scene of the opening conflict of the revolution. He lived at first in an old 'gambrel-roofed' house built by his grandfather, the Rev. William Emerson, and afterwards celebrated as the 'Old Manse' of one of Hawthorne's stories, and the place where for a time he resided. In 1835 he married his second wife, Miss Lydia Jackson of Plymouth, Massachusetts. After this marriage, Mr and Mrs Emerson removed to the house which he purchased, where he passed the rest of his days, and where his widow and one of his daughters are still living (1889).

During several successive years he delivered courses of lectures in Boston; in 1835 ten lectures on English literature, in 1836 twelve lectures on the philosophy of history, in 1837 ten lectures on human culture.

Emerson made the personal acquaintance of Carlyle during his first visit to Europe in 1833. Carlyle was then living at Craigenputtock, where Emerson sought him out, and passed time enough with him for some conversation, of which he has given an account in the first chapter of *English Traits*. In the next year, 1834, a letter from Emerson to Carlyle began a correspondence which continued nearly forty years, closing with the letter from Carlyle to Emerson, dated April 2, 1872. This correspondence, which has been carefully edited by Professor Charles Eliot Norton, shows the two men with all their characteristics; different as optimist and pessimist, yet with many profound sympathies with each other. Emerson was very desirous of having Carlyle come to stay with him at Concord. It would have been a dangerous experiment in vital chemistry—hydrofluoric acid in a vessel of glass. The deaths of Emerson's younger brothers, Edward in 1834, and Charles in 1836, produced a very deep impression on his affectionate nature. He had a true admiration for both of them, which they well deserved. The youngest, Charles Chauncy Emerson, well remembered by the present writer, stands apart from all the young men he has known for the elevation and beauty of his intellect and character.

In 1836 a thin volume was published, entitled *Nature*, which, though appearing anonymously, was at once known as coming from Emerson. Like his early poems, it was read by few, understood by fewer still, little thought of or cared for by the general reading public, but made much of by a small circle of admirers. It is a kind of poetical rhapsody—prose with wings growing, but not strong enough to lift it into the atmosphere of rhythmical music. To those who like nature, naturally, or have acquired the taste for, the Emersonian modes of thought and expression, it is fascinating. But it took twelve years to sell five hundred copies. The germs of many of Emerson's thoughts, afterwards expanded in his essays and poems, may be found in this dreamy little volume.

*Nature* was followed by 'The American Scholar,' an oration delivered before the Phi Beta Kappa Society of Harvard University. Few anniversary addresses have attracted so much attention. Mr Lowell says of it that 'its delivery was an event

without any former parallel in our literary annals, a scene to be always treasured in the memory for its picturesqueness and its inspiration.' This grand oration was our intellectual declaration of independence. The orator did not spare his fellow-countrymen. 'We have listened too much,' he says, 'to the courtly muses of Europe. The spirit of the American freeman is already suspected to be timid, imitative, tame. The scholar is decent, indolent, complacent.' The young men of promise, he says, are discouraged and disheartened. 'What is the remedy? If the single man plant himself indomitably on his instincts and there abide, the huge world will come round to him. Patience—patience; with the shades of all the good and great for company; and for solace the perspective of your own infinite life; and for work the study and the communication of principles, the making those instincts prevalent, the conversion of the world.'

These two publications, the first in the series of his collected works, strike the keynote of his philosophical, poetical, and moral teachings. The 'Address before the senior class in Divinity College, Cambridge, July 1838,' which follows them, defined his position in, or out of, the church in which he had been a minister. Two or three sentences will sufficiently show where he stood: 'One man was true to what is in you and me. He saw that God incarnates himself in man, and evermore goes forth to take possession of his world. He said in this jubilee of sublime emotion, "I am divine. Through me God acts; through me speaks." . . . There is no doctrine of the Reason which will bear to be taught by the Understanding. The Understanding caught this high chant from the poet's lips and said, in the next age, "This was Jehovah come down out of heaven. I will kill you if you say he was a man."' In its simplest and broadest statement this discourse was a plea for the individual consciousness as against all historical creeds, bibles, churches; for the soul of each man as the supreme judge in spiritual matters. The delivery and publication of this address produced a great sensation in the religious world, especially among the Unitarians. Professor Andrews Norton attacked Mr Emerson's position in an article entitled 'The Latest Form of Infidelity.' Much controversy followed, in which Emerson took no part. He was not in the habit of defending his oracular statements. Delphi is not given to argument and explanation.

Whosoever has read carefully and lovingly these three essays, *Nature*, the *Phi Beta Kappa Oration*, and the *Divinity School Address*, can almost say of Emerson what he makes the Sphinx say of herself:

Who telleth one of my meanings  
Is master of all I am.

These three essays take up about one-third of the first volume of his collected works, which are eleven in all. The titles of these volumes are as follow: Vol. i. *Nature; Addresses and Lectures*; ii. and iii. *Essays*, first and second series; iv. *Representative Men*; v. *English Traits*; vi. *The Conduct of Life*; vii. *Society and Solitude*; viii. *Letters and Social Aims*; ix. *Poems*; x. *Lectures and Biographical Sketches*; xi. *Miscellanies*. These titles, and the more special ones which are included within them, give a very imperfect and unsatisfying idea of the contents of the eleven volumes. If these were taken to pieces, and their leaves thrown into a basket or barrel and shaken up, they might be taken out and rearranged in a dozen different ways, and yet have cohesion enough to make almost as intelligible consecutive reading as they are in their present order. Their arrangement under their different heads is nearly as

arbitrary as that of certain stars which are grouped under the name of Corona, or Lyra, or Andromeda. His son, Dr Edward Emerson, gave this account of his way of building his lectures in a paper, to the reading of which I had the privilege of listening: 'All through his life he kept a journal. . . This book, he said, was his "Savings Bank." The thoughts thus received and garnered in his journals were indexed, and a great many of them appeared in his published works. They were religiously set down just as they came, in no order except chronological, but later they were grouped, enlarged or pruned, illustrated, worked into a lecture or discourse, and after having in this capacity undergone repeated testing and rearranging, were finally carefully sifted and more rigidly pruned, and were printed as essays.'

We can easily understand that in adjusting his mosaic fragments to each other there are likely to be occasional misfits which puzzle weary eyes and brains. Still, there are subtle connections oftentimes in thoughts which at first sight seem unrelated, and the pious reader of Emerson will always find it worth while to seek for them, though some of them may be 'hard for the non-elect to understand.'

Emerson wrote occasionally in verse from his schooldays until he had reached the age which used to be known as 'the grand climacteric,' sixty-three. *Terminus*, which he read to his son in 1866, is, so far as I know, the last poem he wrote. It is a farewell to his literary life, though he made some efforts in after-years. His poems are to his prose what the corolla is to the calyx. Both spring from the same root; both are modifications of the same growth; the sepal often shows the delicacy and colour of the petal, and the petal often lapses into the homelier texture and complexion of the sepal. His poems are not and hardly can become popular; they are not meant to be liked by the many, but to be dearly loved and cherished by the few. Such poems as *The Problem*, *Fate*, and *Days*, once rightly read, are never forgotten. The influence of Marvell, of George Herbert, of the Persian poets, of whom he was very fond, may be frequently traced; but the writer he most reminds us of, whatever he writes, is—Emerson. His occasional lawlessness in technical construction, his sometimes fantastic expressions, his enigmatic obscurities hardly detract from the pleasant surprise his verses so often bring with them. His teachings have not always had a wholesome effect on his train of imitators and followers in poetry, or what was meant for poetry. It was very well for him to find fault with 'the tinkle of piano-strings,' and say that

The kingly bard  
Must strike the strings rudely and hard  
As with hammer or with mace;

but if a self-crowned 'kingly bard' undertakes to play on the harp or piano with his fists instead of his fingers, we must beg leave to stop our ears. The magnificent lawlessness of 'Lord' Timothy Dexter in punctuation is a bad precedent for poets to follow in composition. The poetic license which we allow in the verse of Emerson is more than excused by the noble spirit which makes us forget its occasional blemishes, sometimes to be pleased with them as characteristic of the writer.

The idealist in philosophy, the rationalist in religion, the bold advocate of spiritual independence, of intuition as a divine guidance, of instinct as a heaven-born impulse, of individualism in its fullest extent, making each life a kind of theocratic egotism; all this may be seen in every one of his larger utterances. For him nature is a sphinx, written all over with hieroglyphics for which the spirit of man is to find the key. To interpret

nature is the province of the thinker, and especially of the poet—not as Bacon intends, by the analysis of phenomena—'natural philosophy'—but by detecting the higher, hidden significance of all natural appearances. He had learned from his wise relative, Aunt Mary Moody Emerson, to 'scorn trifles;' he bettered his lesson by teaching that man is made to scorn heaven itself if a higher empyrean is offered to him.

The fount that man harries  
Is love of the Best. . .  
The heaven that now draws him  
With sweetness untold  
Once found—for new heavens  
He spurneth the old.

Throughout his lectures and essays are scattered wise sayings, shrewd observations, delicate strokes of wit, curious gleanings from his widely discursive reading, and eloquent imaginative passages. But above all the special virtues to be found in his writings in prose and in verse we must recognise the sense of being in relation with a pure and lofty spiritual nature. 'Love of the Best' breathes in every expression of his thought. His writings must be read for their inspiring influence, their stimulus to high thought and endeavour, the noble manhood which pervades them. Recognising these as the chief claims of Emerson's essays and poems, we can delight in their singular and distinctive beauty of expression, their delicate wit, their iridescent variety of unexpected suggestions, their unaffected and often unconscious archaisms, which carry the reader's imagination back to his favourite Montaigne, their happy illustrations, their self-sustaining wisdom.

Emerson loved his quiet Concord life, the repose of which was, however, constantly broken by more or less welcome visitors, who sought him as an oracle. He was long-suffering with those 'devastators of the day,' as he called them, each of whom thinks of himself or herself as a privileged intruder. He travelled far and wide as a lecturer. In *English Traits* he has recorded not so much what he saw as what he thought while visiting England and Scotland, and in reflecting on his tour after his return. At home he was, according to village evidence, 'a first-rate neighbour, and one who always kept his fences up.'

Emerson was strongly opposed to slavery, but not conspicuous as an abolitionist. He would have bought out the slave-holders, and if men did not cling closer to their money than they do to their lives, his idea might have had some reason in it. He looked on at the 'Brook Farm' experiment with a kind of amused interest, but took no active part in the project. He listened to the long-haired reformers who swarmed at one time about the Chardon Street Chapel with a kindly curiosity, but his sense of humour as well as his good judgment was his safeguard, and he was not to be betrayed into any fanatical extravagance.

His personal appearance was that of the typical New Englander of college-bred ancestry. Tall, spare, slender, with sloping shoulders, slightly stooping in his later years, with light hair and eyes, the scholar's complexion, the prominent, somewhat arched nose which belongs to many of the New England sub-species, thin lips, suggestive of delicacy, but having nothing like primness, still less of the rigidity which is often noticeable in the generation succeeding next to that of the men in their shirt-sleeves, he would have been noticed anywhere as one evidently a scholarly thinker astray from the alcove or the study, which were his natural habitats. His voice was very sweet, and penetrating without any loudness or mark of effort. His enunciation was beautifully clear, but he often hesitated as if waiting for the right word to present

itself. His manner was very quiet, his smile was pleasant, but he did not like explosive laughter any better than Hawthorne did. None who met him can fail to recall that serene and kindly presence, in which there was mingled a certain spiritual remoteness with the most benignant human welcome to all who were privileged to enjoy his companionship.

Much has been written about Emerson during his life and since his death. Some of the principal sources of information about him are *A Memoir of Ralph Waldo Emerson*, by James Elliot Cabot (Houghton & Mifflin, Boston and New York, 1887), which is the authoritative life of Emerson, by his literary executors; *Ralph Waldo Emerson, Life, Writings, and Philosophy*, by G. W. Cooke (James R. Osgood & Co., Boston, 1882); *Emerson at Home and Abroad*, by Moncure Daniel Conway (James R. Osgood & Co., Boston, 1882); *Ralph Waldo Emerson, a Biographical Sketch*, by Alexander Ireland (Simpkin, Marshall & Co., Lond. 1882); *Ralph Waldo Emerson*, in 'American Men of Letters,' by Oliver Wendell Holmes (Houghton, Mifflin & Co., Boston, 1885); *Emerson in Concord*, by his son Edward Waldo Emerson, a most interesting personal memoir (Houghton, Mifflin & Co., Boston, 1889). Emerson's complete works, edited by James Elliot Cabot, are published in a uniform edition, making eleven duodecimo volumes, by Messrs Houghton, Mifflin & Co., Boston, U.S., and by Macmillan & Co., London, in six volumes, with preface by John Morley.

**Emery**, the 'Armenian whetstone' of Theophrastus, is a variety of Corundum (q.v.), the mineral species which embraces ruby, sapphire, and other oriental precious stones, variously named according to their colour. The precious stones mentioned consist of nearly pure alumina in a crystalline condition, while emery is an amorphous admixture of alumina with varying proportions of oxide of iron and silica. Next to the diamond, these minerals are the hardest substances found in nature; but the hardness of emery is modified by the amount of iron and silica which enter into its composition. In external appearance, emery has nothing in common with the brilliant stones to which it is related, being a dense, opaque, dull, bluish-black substance, like a fine-grained iron ore. It occurs in large boulder-like masses on Naxos and some of the other islands of the Greek Archipelago, these being the principal commercial sources of the material.

It is prepared for use by first breaking it into lumps about the size of a hen's egg, then crushing these to powder by stampers. It is then sifted to various degrees of fineness, which are numbered according to the meshes of the sieve. Plate-glass manufacturers and others separate emery-powder into different degrees of fineness by the method of Elutriation (q.v.). Emery thus prepared is used for a great many important purposes in the arts. Being next in hardness to diamond-dust and crystalline corundum, the lapidary uses it for cutting and polishing many kinds of stone. Glass stoppers of all kinds are ground into their fittings with it. Plate-glass is ground flat by its means; it is also used in glass-cutting, and in grinding some kinds of metallic fittings. When employed for the polishing of metals, it has to be spread on some kind of surface to form a sort of fine file. *Emery-paper*, *emery-cloth*, *emery-sticks*, *emery-cake*, and *emery-stone* are various contrivances for such purposes. Emery-wheels are also largely used for smoothing and polishing the surface of iron castings, and in engineering work generally. These wheels consist principally of a mixture of emery-powder and hard vulcanised india-rubber. The polishing and buffing wheels employed by cutlers are also fed with emery-powder. See **POLISHING**.

**Emesa.** See **HEMS** or **HOMS**.

**Emetics**, medicines given for the purpose of producing Vomiting (q.v.). They are given when

it is desirable to relieve the stomach of some noxious or indigestible substance, such as a narcotic poison, or excess of food, or some special article of diet which has disagreed. Emetics are also administered in cases of fever, where the copious secretion they produce from the glands of the stomach and intestines is supposed to have a directly emative effect, aided, perhaps, by the sedative action of emetics upon the circulation and nervous system. There is a considerable amount of evidence to show that emetics have the power of enting short typhus and other fevers in the earliest stage, and afterwards of making the attack of the disease less severe. In diseases of the respiratory organs, emetics are given as the quickest and safest method of removing accumulated mucus from the air-passages; and in Croup (q.v.) their action is especially favourable, being often followed by expectoration and a rapid improvement in the suffocative symptoms. Emetics are to be given with great caution, however, in all very depressed states of the system, as their primary action is to produce nausea, which is attended always with more or less diminution of the vital power, and often with great depression of the heart's action, amounting to syncope or fainting. Emetics may produce vomiting either by their local action on the throat, gullet, and stomach, or by their action through the blood on the nervous mechanism regulating the movements of the stomach. They are thus divided into two groups, *local* and *general* emetics; and the depressing effect of the former is much less than that of the latter. Some substances will produce vomiting in either way; so that the distinction between the two classes is not very definite. Among the chief emetics in use are mustard (two tablespoonfuls), common salt (a tablespoonful or more), alum (a teaspoonful), in a tumblerful of water, repeated after a quarter of an hour if necessary. These, with sulphate of copper or zinc, are mainly local in their action; ipecacuanha and emetin, squills, senega, tartar emetic and other soluble salts of antimony, apomorphia, are mainly general in their action. The production of vomiting is aided, whatever emetic is used, by copious draughts of warm water. Tickling the throat with a finger or feather is often an effective mechanical means to produce vomiting.

**Emetin** is the alkaloid which forms the active principle of ipecacuanha-root. It may be obtained by drying the powdered root-bark with milk of lime, and then exhausting with boiling chloroform. It is a white powder, becoming brown on exposure to light, slightly soluble in water, but readily in alcohol. When taken internally, it exhibits violent emetic properties, a little of a grain sufficing to cause vomiting. The wood of the root contains no emetin, so that the virtue of ipecacuanha-root entirely resides in the bark.

**Emigration** literally means going from one place to another; but in its established signification it implies (1) permanently leaving a place to make a home elsewhere; (2) going out of one country to another, and generally to a distant part of the world; (3) going out from a community and leaving the bulk behind—in this sense the word is opposed to migration, which implies the movement of whole tribes or nations; (4) going out spontaneously, not as part of some systematic scheme of settlement—in this sense the word has been sometimes opposed to colonisation. In the country which people leave they are called emigrants or wanderers out; in that in which they settle they are usually called immigrants. Jacob and his family were immigrants to Egypt, and their descendants became emigrants from that country when they went to inherit the Promised Land.

Among the principal causes which have led to emigration at different times in history may be noticed the pursuit of wealth, the pressure of population at home, and political, social, or religious discontent. The Spaniards went to America to get gold. Many of the Greeks in old times, like many of the English in our own, emigrated because of over-population. Political and social discontent, as well as over-population, accounts in great measure for the large numbers of Irish emigrants. The burden of compulsory military service is supposed to be, and to have been, one determining cause of German emigration. And religious oppression led to the emigration of the Huguenots from France to England, and of the Puritans from England to North America.

In ancient times, when the Mediterranean was the centre of the world, the Greek race sent out most emigrants. The Phœnicians were rather traders than settlers, and the Roman colonies were mainly military stations, carefully designed by government. The Greeks emigrated because their space was limited at home compared with their numbers, and because in the small towns which made up Greece party spirit ran high, and often led to large bodies of citizens leaving for a new home. Greek emigrants settled along the shores of the Mediterranean, from Cyprus in one direction to Marseilles in another, and these settlements were quite independent of, and in many cases greater than, the mother-cities.

Between ancient and modern times there intervenes a long period of the world's history, during which there was a perpetual ebb and flow of races throughout Europe; but the movements of the barbarians who overran the provinces of the Roman empire, and even the later and more organised enterprises of such peoples as the Normans, fall rather under the head of migration, invasion, or conquest, than under that of emigration. At the end of the 15th century, the opening of the passage to India round the Cape of Good Hope by Vasco da Gama, and the discovery of America by Columbus, at once disclosed new lands to which Europeans might emigrate, and stimulated the restless spirit which prompts to emigration. The Spaniards went to the west, the Portuguese to the east; and, being natives of the south of Europe, they were better fitted than the more northerly nations to make their homes in hot climates. Large numbers of Spaniards emigrated to the West Indies and to Central and South America. The Portuguese were fewer in numbers, and the East Indies, to which at first they chiefly went, were less suitable than America for European settlement; still, at the present day, their descendants are left in India, Ceylon, and elsewhere. To Brazil, which was outside their beat, they found their way by accident, and that country became the home of many Portuguese. Among the nations who followed the Portuguese and Spaniards to the east and west were the Dutch, the French, and the English. The Dutch, though great traders, did not send out many emigrants compared with other colonising peoples; but in addition to those who were attracted to the East Indies by commerce, Dutchmen emigrated to what is now known as New York, and still more to the Cape of Good Hope. The French were rather conquerors than settlers, but many Frenchmen emigrated to various parts of the world, as to the islands of Mauritius and Bourbon, to some of the West Indian islands, to Louisiana, and notably to Canada, where their descendants are now multiplying very fast. The English emigrated principally to the West Indies, to North America, and later to Australasia and South Africa.

European emigration has been greatest in the 19th century, because the population of Europe has

increased so enormously. It is necessary to consider (1) the countries to which the emigrants go; (2) the countries from which they come. As regards the former, it is obvious that the favourite fields for European emigration must always be (a) countries with a suitable—i.e. a temperate climate; (b) countries which have not an over-large population already; (c) countries which have large resources—i.e. large facilities for making wealth. Tried by these tests, it is clear that, as has actually been the case, the United States and British North America, the Australasian colonies of Great Britain, South Africa (though there the native population is large), and the more temperate parts of South America—e.g. the Argentine Republic—would be the places which would attract most emigrants.

As regards the countries from which the emigrants come, the Teutonic nations have supplied the largest number, including English, Germans, and Scandinavians. The Germans have gone in great measure to the north central districts of the United States, the Swedes to Minnesota and Canada. Latterly there has been a large emigration from Iceland to Canada. Of the Celtic peoples the Irish have emigrated in largest numbers, mainly to the United States. There, in 1880, according to the census, the number of inhabitants of Irish origin formed 3·70 per cent. of the total population, as against 3·92 per cent. German born, while in the city of New York the Irish element amounted to 16·5 per cent. of the population. In the record of Welsh emigration, mention may be made of the interesting Welsh settlement on the Chubut (q.v.) River in Patagonia. Of the Latin peoples, France sends out but few emigrants, owing mainly to the absence of any marked increase in her population; on the other hand, there is a large stream of Italian emigration to the Argentine Republic.

Great Britain not only furnishes a very large proportion of the total number of European emigrants, but is also a place through which very many foreigners pass on their way to America. The returns issued by the Board of Trade show that during the thirty-six years 1853-88, 8,675,475 emigrants left British ports for places out of Europe. Of these 6,650,055 were of British and Irish origin, 49 per cent. being English, 10 per cent. Scotch, and 41 per cent. Irish. Of the total number, 6,012,043 went to the United States, 912,477 to British North America, 1,324,018 to Australasia, 426,937 to all other places. Emigration from British ports is subject to the Passengers Acts, which are administered by the Board of Trade, and which contain provisions for the proper food, accommodation, and medical care of emigrants. For many years there was a Colonial Land and Emigration Board, subordinate to the Colonial Office; but with the gift of responsible government to the larger colonies, the consequent handing over of the public lands to the colonial governments, and the growing number of settlers, the functions of the board became necessarily curtailed, and such work as remained to it, consisting mainly of the supervision of coolie emigration from India to some of the tropical Crown Colonies, has been transferred to the Colonial Office. In 1886 a small office, managed by a voluntary committee, but subsidised by the government, and under the general control of the Colonial Office, was established at 31 Broadway, Westminster, S.W., for giving accurate and useful information to intending emigrants to the British colonies. The number of written and verbal applications made to this office is a proof of the great interest which attaches to the question of emigration at the present time. There are various acts in existence authorising the application of public funds to purposes of emigration. Powers are given to the guardians in England and Wales to apply money to this purpose under certain

conditions, and the Local Government Bill of 1888 authorises a County Council to advance money for emigration or colonisation, if the repayment is guaranteed by a local authority in the county, or by the government of a colony. State aid to emigration has also been sanctioned under certain Irish acts and in the case of the crofters of Scotland.

Writing of emigration from Great Britain in 1889, we may summarise the main points of interest as follows: (1) There is a growing movement in favour of supplementing the efforts of voluntary emigration societies by state aid given directly or indirectly on a large scale. This movement is due to the great growth of population at home, the distress caused till quite lately by bad trade, and the congestion of labour in the large towns. (2) Colonisation as opposed to emigration is attracting much attention—i.e. the sending out large bodies of people, on a well-defined system, to a particular place and a fixed employment, as opposed to the sending out isolated individuals or families to take their chance in a new country. (3) While the interest in emigration is growing rather than declining at home, the feeling in the countries which are the main fields of labour is not so favourable to efforts in this direction. But little assistance to emigrants is now given by the colonial governments, Queensland being the most liberal; and the assistance, when given, is mainly confined to farmers, farm-labourers, and female domestic servants. The feeling against emigrants in the United States and in the British—notably the Australasian—colonies (as to which see also under IMMIGRATION) is due partly to the jealousy of imported labour felt by the working-classes on the spot, partly to past experience of the many unsuitable emigrants sent out in former years; fortunately (4) it is now being recognised that the quality of the emigrants is more important than the quantity, that paupers and vicious or infirm persons are not desirable settlers, that among able-bodied men of good character country-people rather than towns-people are wanted in the colonies, and that it may be possible at once to meet the requirements of the colonies and to relieve the pressure at home by sending out those who would otherwise flock into the towns from the country-districts. (5) It only remains to point out that among British colonies there has latterly (up to the end of 1888) been a falling off in the numbers of emigrants to Australasia, and on the other hand an increase in the number of emigrants to Canada; that the discovery of gold in the Transvaal has given a stimulus to emigration to South Africa; and that the Argentine Republic is now attracting much attention as a field for British settlers, an information office for emigrants having been established in London by the Argentine government.

What has been said above refers exclusively to emigration from Europe. A few words should be added as to Chinese and Indian emigration. The opposition offered to unrestricted Chinese immigration in the United States and in the Australasian colonies shows the importance which is attached to the question of Chinese labour, and the dimensions to which it is anticipated that Chinese immigration might attain. Taking the British dependencies, Chinese emigrants have gone to British Columbia, to Queensland and other parts of Australia, to Labuan and North Borneo, and most of all to the Straits Settlements and the protected states of the Malay Peninsula, in the mining districts of which they now far outnumber the native Malays. Hong-kong is the main outlet for Chinese emigration, and at one time some difficulty was experienced by the government in checking abuses connected with indentured coolie emigration to South America. Speaking of Chinese emigration

generally, the most noticeable points are (1) the numbers which emigrate; (2) the disproportion of the sexes, the enormous bulk of the emigrants being males; (3) the absence, to a certain extent, of the permanent element, as a large number of the emigrants return to China. Indian emigration is for the most part indentured emigration, whereas Chinese emigration is in great measure quite independent of any contract to employers. Under the contract system, Indian coolies have been imported into various parts of the British colonial empire, the West Indies, Fiji, the Malay Peninsula, and Mauritius. In some of the West Indian dependencies, in British Guiana, and in Mauritius, the system has led to a large resident Indian population; in Mauritius its results are that, after fifty years of Indian immigration, two-thirds of the population of the island are Indians. It need hardly be said that the system required to be, and has been, carefully kept under government control, in order to preclude the possibility of this species of emigration becoming a modified form of slavery. See under IMMIGRATION, COOLIES; and the article COLONY.

**Émigrés**, the name given more especially to those persons who quitted France during the Revolution. After the insurrection at Paris, and the taking of the Bastille, 14th July 1789, the princes of the royal family departed from France. They were followed, after the adoption of the constitution of 1791, by all who considered themselves aggrieved by the destruction of their privileges, or who were exposed to persecution. Nobles quitted their châteaux; officers, with whole companies, passed the frontiers. Crowds of priests and monks fled to escape the oath of allegiance to the constitution. Belgium, Piedmont, Holland, Switzerland, and, above all, Germany, were overrun with fugitives of every age. Only a few had been able to save their property; the greater portion were in a state of destitution, and sank into utter demoralisation. A court had formed itself round the princes at Coblenz; a government, with ministers and a court of justice, had been established, and communication was kept up with all the foreign courts unfavourable to the Revolution. This conduct embittered France, aggravated the position of the king, and drove the revolutionary party forward in their sanguinary career. Under the command of the Prince of Condé, a body of émigrés was formed, which followed the Prussian army into Champagne. The result was that the severest laws were now put in force against the émigrés; their lands were confiscated; the penalty of death was proclaimed against any one who should support or enter into communication with them; thirty thousand persons were placed upon the list of émigrés, and exiled for ever from the soil of France, although many of them had refused to bear arms against their country. Not until after the failure of their attempt to land at Quiberon in 1795 did the émigrés abandon all thoughts of penetrating into France by force of arms. Condé's corps, after the peace of Lunéville, was obliged formally to dissolve, and sought an asylum in Russia. Even under the Directory, however, many had endeavoured to obtain permission to return to France. The general amnesty proclaimed by the First Consul was therefore joyfully hailed by the greater portion of the émigrés, though many did not return home till after the downfall of Napoleon. Dignities, pensions, and offices were now showered upon these faithful adherents; but, according to the charter of 1814, they were unable to recover either their estates or their privileges. Finally, on the motion of the minister Villèle, the émigrés who had lost their landed estates received, by the law of the 27th April 1825, a compensation of 30 million francs yearly on the capital of 1000 million francs. After

the July revolution, however, the grant was withdrawn. See Saint-Gervais, *Histoire des Emigrés Français* (1823), and the works by Montrol (1825), Forneron (3d ed. 1834), and Puymaigre (1884).

**Emilia**, a name now employed to designate a compartimento of Central Italy, comprising the provinces of Bologna, Ferrara, Forlì, Modena, Parma, Piacenza, Ravenna, and Reggio Emilia. The name is derived from the ancient *Via Emilia* (a continuation of the *Via Flaminia*, or great northern road), which passed through these territories. See ITALY.

**Eminence**, a title given by Urban VIII., in 1631, to cardinals, who up to the period of his pontificate had been called Most Illustrious.

**Eminent Domain**, a phrase which occurs more commonly in its Latin form, *dominium eminens*, denotes the universal right in the public over property, by virtue of which the supreme authority in a state may compel a proprietor to part with what is his own for the public use. Thus a private owner may be compelled to give up part of his land that a public highway may be made through his ground. For the just exercise of this right there must be a necessity or clear public utility in the work proposed; and the expropriated owner must be compensated for his loss. The right is now exercised only under well-defined statutory regulations, as in the Lands Clauses Consolidation Act, 1845, which regulates the purchase of lands for railways and other public undertakings.

**Emm Pasha**. See SCHNITZER (EDUARD).

**Emir** (plur. *Omrah*), an Arabic word, equivalent to 'ruler,' is a title given in the East, and in the North of Africa, to all independent chieftains, and also to all the actual or supposed descendants of Mohammed through his daughter Fatima. The latter are very numerous throughout the Turkish dominions, but, although entitled by birth to be classed among the first of the four orders of society, they enjoy no particular privileges or consideration, and are found engaged in all sorts of occupations. Their privileges are confined to a few unimportant matters, chiefly to the exclusive right to wear turbans of a green colour, that having been the favourite colour of the Prophet. They are placed under the supervision of the Emir-Beshir. The title Emir, in connection with other words, likewise designates different offices. *Emir-el-Mumenin*, 'Prince of the Faithful,' is the title assumed by the califs themselves, while *Emir-al-Omrah*, 'Prince of Princes,' was the title of their first minister. The Turkish master of the horse is styled *Emir-Achor*; the standard-bearer, *Emir-Alem*; and the leader of the caravans of pilgrims to Mecca, *Emir-Hadji*. *Amir*, *Ameer*, and *Amer* are other spellings of the same word. Admiral (q.v.) is a derivative.

**Emission Theory**. See LIGHT.

**Emmanuel**, or IMMANUEL (Heb., 'God with us'), was the symbolical name of the child announced by Isaiah to Ahaz and the nation (Isa. vii. 14), and applied by St Matthew to the Messiah born of the Virgin (Matt. i. 23).

**Emmaus**, a village of Judea, not far from Jerusalem (Luke, xxiv. 13), which after the Jewish war was colonised with 800 Roman veterans. A writer in the quarterly statement of the Palestine Exploration Fund (January 1883) identifies it with the valley of the Urtas, 7 miles from Jerusalem, and south of Bethlehem, where costly baths have been discovered.

**Emmenagogues**, medicines intended to restore, or to bring on for the first time, the menses in women. See MENSTRUATION.

**Emmerich**, an old walled town of Rhenish Prussia, on the Rhine, near the borders of Holland, 94 miles by rail E. of Rotterdam. It has manufac-

tures of iron, glass, tobacco, &c., besides an active river trade. From a small Roman colony the town grew in importance until, in the 15th century, it had 40,000 inhabitants; from 1592 to 1811 it was the seat of a famous Jesuit seminary. Pop. (1875) 8117; (1885) 9759.

**Emmet**, ROBERT, an ill-fated Irish patriot, was born in Dublin in 1778, the youngest son of the physician to the viceroy. At fifteen he entered Trinity College, where Moore was a fellow-student, but an academic career of exceptional promise was soon cut short by his joining the United Irishmen. He next travelled on the Continent, interviewed Napoleon and Talleyrand in 1802 on behalf of the Irish cause, and returned the next year to devote his own fortune of £3000 to buying muskets and manufacturing pikes. With a few confederates he laid a plot to seize Dublin Castle, and secure the person of the viceroy, but the rising proved a complete failure, and Emmet, who had arrayed himself for the occasion in a green coat, white breeches, and cocked hat, had the mortification to see nothing result from his enterprise but a few ruffianly murders. He escaped to the Wicklow Mountains, but returning for a last interview with his sweetheart, Sarah Curran (q.v.), the daughter of the orator, was arrested, put on trial on 19th September 1803, condemned to death, and hanged the following day. Just before receiving sentence he delivered a speech which still thrills the reader by its noble and pathetic eloquence. See the biography in Madden's *Lives of the United Irishmen*, 3d series, vol. iii. (1846).

**Emmet**. See ANT.

**Emollients** (from Lat. *mollis*, 'soft'), substances used to soften the textures to which they are applied, as poultices, fomentations, &c., externally, and Demulcents (q.v.) internally.

**Emotion**, a word used in philosophy with some considerable variety of meaning. The phenomena of the mind may be divided into three groups—cognitions, emotions, and volitions, into intellect or thought, feeling, and will. The emotions taken in this sense constitute one of the great groups of mental activities. They may be pleasurable, painful, or neutral, and may be arranged according as they arise directly out of the senses, movements, and appetites or not. In the latter case they comprise feelings of freedom and restraint, wonder, terror, love, self-complacency, the sense of power, anger, love of knowledge, artistic emotions, the moral sense, &c. As they combine and pass into one another by infinite gradations, a systematic and exhaustive classification is impossible. Sometimes emotion implies that the feeling is keenly experienced, so as to occasion mental disturbance. The expression of the emotions, especially in the face, was carefully studied by Sir Charles Bell; and Darwin's *Expression of the Emotions in Man and Animals* (1873) is a monument of patient observation and insight. The emotions act powerfully on the organic functions of the body, as illustrated in blushing, quicker or slower pulsation of the heart, cold perspiration, &c. The term *feeling* is used with even greater laxity than emotion. It is sometimes the perception we have of extreme objects, of their being hard or soft, hot or cold, in which case it is the intellectual function of sensation, or the sensation itself. Again, it may be specifically pleasure, pain, or the neutral emotion, or emotion in the widest sense. Or it may be used loosely for almost any kind of consciousness, as by James Mill. The higher feelings, as the appreciation of the sublime and beautiful, approval and disapproval, are often termed sentiments. See the manuals of psychology, such as Bain's *The Emotions and the Will*.

**Empecinado**, DON JUAN MARTIN DIAZ, EL, one of the leaders of the Spanish revolution of 1820, was born in 1775, and entered the Spanish army in 1792. He carried on a guerilla warfare against the French during the Peninsular struggle, and acquired great distinction. In 1814 he was appointed colonel in the regular army, and the king himself created him field-marshal; but in consequence of petitioning Ferdinand, in 1815, to reinstitute the Cortes, he was banished to Valladolid. On the outbreak of the insurrection in 1820 he took a prominent part on the side of the constitutionalists; after the triumph of the absolutists in 1823 he was arrested, exposed in an iron cage to the contumely of the passers-by, and finally, while struggling with his executioners, stabbed by one of the soldiers.

**Empedocles**, a Greek philosopher of Agrigento, in Sicily, lived about 450 B.C. So great was the estimation in which he was held by his fellow-citizens as a physician, a friend of the gods, a predictor of futurity, and a magician, that they are said to have offered him the sovereignty. But being an enemy of tyranny, he declined it, and was the means of delivering the community from the dominion of the aristocracy, and bringing in a democracy. There was a tradition that he threw himself into the crater of Etna in order that his sudden disappearance might beget a belief in his divine origin; this, however, can only be regarded as a mere fable, like the story told by Lucian, that Etna threw out the sandals of the vain philosopher, and thus destroyed the popular belief in his divinity. In Matthew Arnold's poem, *Empedocles on Etna*, the philosopher is represented as superior to vanity and superstition, but moody and out of sympathy with his contemporaries.

In Empedocles philosophic thought is bound up with poetry and myth even more closely than in Parmenides (q.v.). His general point of view is determined by the influence of the Eleatic school upon the physical theories of the Ionic philosophers. He assumed four primitive independent substances—air, water, fire, and earth, which he designates often by the mythical names Zeus, Hera, &c. These four *elements*, as they were called, kept their place till modern chemistry dislodged them. Along with material elements he affirmed the existence of two moving and operating powers, love and hate, or affinity and antipathy, the first as the uniting principle, the second as the separating. The contrast between matter and power, or force, is thus brought out more strongly by Empedocles than by previous philosophers. His theory of the universe seems to assume a gradual development of the perfect out of the imperfect, and a periodical return of things to the elemental state, in order to be again separated, and a new world of phenomena formed. Of his opinions on special phenomena may be mentioned his doctrine of emanations, by which, in connection with the maxim that like is known only by like, he thought to explain the nature of perception by the senses. He attempted to give a moral application to the old doctrine of the transmigration of souls, his views of which resembled those of Pythagoras. The fragments of Empedocles have been edited by Sturz (1805), Karsten (1833), and Stein (1852). See monographs by Lommatsch (1830), Raynaud (1848), and Gladisch (1858).

**Emperor** (Lat. *imperator*), a title formerly borne by the heads of the Roman empire, and which in the modern world has become the highest title of sovereignty. In Rome the *imperium* of a magistrate, whether king or consul, was the power which he possessed of bringing physical force into operation for the fulfilment of his behests. This power was conferred by a *lex curiata*, and it required this authorisation to entitle a consul to

act as the commander of an army. In the case of the kings also the *imperium* was not implied in their election, but was conferred separately, by a distinct act of the national will. Now it was in virtue of this *imperium* that the title *imperator* was given to its possessor. Far from being an emperor in the modern sense, he might be a consul or a proconsul; and there were, in fact, many *imperatories*, even after the title had been assumed as a praenomen by Julius Cæsar. It was this assumption which gradually gave to the title its modern significance. In republican times it had followed the name, and indicated simply that its possessor was an *imperator*, or one possessed of the *imperium*; now it preceded it (see CÆSAR), and signified that he who arrogated it to himself was *the emperor*. Nor was it, as has often been mistakenly asserted, merely a military command; it included also the supreme judicial and consequently also the administrative power; and under the empire the office was free from the temporal and local limitations which had accompanied its enjoyment during the republic. From the emperors of the West the title passed to Charlemagne, the founder of the Holy Roman Empire. When the Carolingian family expired in the German branch, the imperial crown became elective, and continued to be so until, in 1806, Francis II. resigned the title, and withdrew to the government of his hereditary dominions, under the title, assumed in 1805, of Emperor of Austria. The title of *imperator*, like that of *basileus* (Gr., 'king'), was frequently assumed in England by the Anglo-Saxon monarchs in imitation of their Roman and Byzantine contemporaries. In addition to the Emperor of Austria, there are now in Europe the Emperor of Russia (since 1547; see CZAR) and Emperor of Germany (1871); and in 1876 the Queen of England assumed the title of Empress of India, in addition to those which she bore previously. The First and Second Empires in France were established in 1804 and 1852; in America there have been Haitian emperors and Mexican, and the empire of Brazil (1822) still survives. Also, modern usage applies the title to sundry semi-civilised monarchs, such as the rulers of Morocco, China, and Japan; and the Turkish sultans assumed it on the fall of the Eastern empire in 1453.

**Emperor Moth** (*Saturnia carpinii*), nearly related to the silkworm moths (*Bombycina*). With the exception of the Death's Head, it is the largest

Emperor Moth, with Caterpillar, Pupa, and Cocoon.

British moth. Its expanse of wings is about three inches; the female is mainly gray, the male from reddish-brown to orange-yellow; each wing bears

a large black eye, with surrounding rings. The caterpillar is green, with short hair, black cross bands, and yellow or reddish tubercles. The cocoons are formed internally of stiff convergent elastic threads, which resist intrusion, but readily admit of egress. The Great Peacock Moth (*Saturnia pyri*) is a very large European form about twice the size of the Emperor. See SILK.

**Emphysema**, in Medicine, an unnatural distension of a part with air. Emphysema of the cellular texture is usually caused by a wound of the lungs or upper air-passages, from which air escapes during respiration into the cellular tissue. It may be confined to the immediate neighbourhood of the wound, or may extend all over the body. Emphysema is rarely produced otherwise than mechanically; but in gangrene and after death collections of fluid in a state of decomposition sometimes give out gases, which penetrate and distend the textures with which they are in contact.

*Emphysema of the lungs* is the name applied to two distinct conditions. (1) *Interlobular or cellular emphysema*, allied to the form described above in that it depends on a wound of the delicate lining-membrane, and that air occupies the interstices of the cellular tissue, is not common, and occurs only in childhood. (2) *Vesicular emphysema* consists in an unnatural distension of some of the natural air-cells or *vesicles* of the lungs, and is almost invariably present in those who have long suffered from chronic bronchitis or asthma, or have in any way been obliged to make excessive respiratory efforts—e.g. in the blowing of large wind-instruments. The walls of the affected vesicles become thinned, and may ultimately disappear between two or more in contact with each other, so that though the apparent size of the lung increases, the surface available for aeration of the blood is actually much diminished, and great shortness of breath results. The same process is common in the horse, and familiar under the name of 'broken wind.' The only treatment possible is that of the condition to which the emphysema is due; for the affected vesicles cannot be restored to their original condition.

**Emphyteusis** (Gr., 'implanting'), in Roman law, a perpetual right in a piece of land, for which a yearly sum was paid to the proprietor. It much resembled a feudal holding. See FEU, FEUDALISM.

**Empiricism**, the name applied to a school in philosophy which admits of nothing as true but what is the result of experience, rejecting all *a priori* knowledge. It arose out of the system of Heraclitus which is elaborately refuted in the *Theætetus* of Plato, and was abhorrent to the lofty idealism of Socrates. Aristotle was an empiricist in so far as experience (*empeiria*) was to him the realisation of the ideal or formal. The philosophy of Descartes established a kind of compromise between one part of knowledge regarded as innate, and another part as empirical or imparted from without. The founder of modern empiricism was Locke, who makes experience the basis of all knowledge, comprehending alike sensation and reflection. Condillac and the other French *philosophes*, rejecting reflection, pushed to an extreme the sensational side of Locke's philosophy, while Berkeley and Hume developed it on other lines to widely differing conclusions. The Common Sense school maintained that the ground of all knowledge was certain primary beliefs or first principles; Kant, on the other hand, found in the *a posteriori* facts of experience the first form of a consciousness which in its ultimate development must become *a priori*. The two elements are inseparably united; thus the *a posteriori* element, the facts, exist for us only under *a priori* conditions. This may almost be said to mark the turning-point of the new philo-

sophy which has demonstrated that the distinction itself is not absolute, or rather that the distinction is itself transcended in the essential unity of knowledge.

The name *empiric* is applied also to one who depends on the accumulations of experience in any branch of knowledge, as in medicine, rather than on the strictly scientific methods of inference and deduction. See, on the one hand, MEDICINE, Vol. VII. pp. 115-16; and, on the other, QUACK DOCTORS.

The term *Empirical Laws* is applied to such as express relationships, which may be merely accidental, observed to subsist among phenomena, but which do not suggest or imply the explanation or cause of the production of the phenomena. They are usually tentative, and form stages in the progress of discovery of causal laws. Bode's law of the distances of the planets from the sun is an example.

**Employers' Liability.** See LIABILITY, MASTER AND SERVANT.

**Empoli**, a town of Italy, in a beautiful and fertile district on the left bank of the Arno, by rail 22 miles WSW. of Florence and 27 E. of Pisa. The collegiate church (1093), with a fine original facade, though the rest of the building was considerably altered in 1738, contains some good paintings and sculpture. Pop. 6719.

**Emporia**, capital of Lyon county, Kansas, on the Neosho, a tributary of the Cottonwood River, 61 miles SSW. of Topeka by rail. It has a foundry and several flaring-mills. Pop. 7759.

**Empson**, SIR RICHARD, the unpopular agent of Henry VII., was the son of a wealthy citizen of Towcester, Northamptonshire, and was trained for the bar. In 1491 he became Speaker of the House of Commons, and in 1504, now a knight, High Steward of Cambridge University, and Chancellor of the Duchy of Lancaster. Throughout Henry's reign he was employed like Edmund Dudley (q.v.) in exacting taxes and penalties due to the crown. His conduct, defended by himself as strictly legal throughout, was by the people regarded as infamous and tyrannical, and in the second year of Henry VIII.'s reign he was convicted of tyrannising and of constructive treason, attainted, and beheaded on Tower Hill with his partner Dudley, 17th August 1510.

**Emption.** See SALE OF GOODS.

**Empyema** (Gr.), an internal suppuration, a word now applied exclusively to a collection of pus in the pleura. See PLEURISY.

**Empyrean**, a word used by the old metaphysical natural philosophers to designate the highest region of light, where the purest and most rarified elements of fire (Gr. *pyr*) existed; and by medieval and modern poets to indicate heaven, the source of light and the home of the blessed.

**Empyreuma** (Gr. *empyreus*, 'I kindle'), the burned smell and acrid taste which result when vegetable or animal substances are decomposed by a strong heat. The cause of the smell and taste resides in an oil called *empyreumatic*, which does not exist naturally in the substance, but is formed by its decomposition.

**Ems**, a river in the north-west of Germany, rises in Westphalia, on the south-west slope of the Teutoburger Wald, flows first in a north-west and then through a moory region in a northern direction, and empties itself into Dollart Bay, an estuary of the German Ocean, after a course of 205 miles. It is navigable as far as Greven (139 miles), and for ocean-going vessels as far as Halte. In 1818 it was connected by a canal with the Lippe, and thus with the Rhine. A canal uniting the Ems with the Jade was in 1889 in progress.

**Emms**, or **BAD EMS**, a bathing-place known to the Romans, and celebrated in Germany as early as the 14th century. It is situated on the river Lahn, 10 miles ESE. of Coblenz by rail. Pop. 6731, a number more than doubled by patients. Its warm mineral springs belong to the class containing soda; the only essential difference between the numerous springs is in the temperature, varying from 80° to 135° F., and in the greater or lesser amount of carbonic acid gas contained in them. Here in 1870 Benedetti got his final answer from King William.

**Emu** (*Dromæus*), a genus of running birds or Ratitæ in the cassowary family. There are two species, both Australian—viz. the Common Emu (*D. novæ hollandiæ*) and the Spotted Emu (*D. irroratus*). They differ from the Cassowaries (q.v.) in several marked features—e.g. the head and neck are feathered except on cheeks and throat, there is no 'helmet,' nor are there wattles on the neck, the bill is broad, and the claws of the three toes are almost of equal length. The emu is a large bird, standing about 6 feet in height. The plumage is like that of the cassowary; the colour is predominantly dull brown, darker on the head, neck, and middle line of the back, lighter beneath. The naked parts of head and neck are grayish-blue, the bill and feet brownish. The young are striped with black. The wings are of course rudimentary, but the legs serve the bird well both in running and kicking.

Common Emu (*Dromæus novæ hollandiæ*).

Timid and peaceful in character, the emu trusts to its speed for safety. It is valued on account of its beef-like flesh, abundant oil, and edible eggs, but is unfortunately being destroyed with too great carelessness. The plains of the interior are now the chief haunts; the food consists chiefly of roots, fruits, and herbage. The note is a curious booming sound. The emu is not polygamous like the Ostrich (q.v.); true pairing occurs. The eggs are placed in a scooped-out cavity in the earth; they have a dark-green shagreen appearance, and measure on an average  $4 \times 3\frac{1}{2}$  inches. About forty are laid in a summer; the male incubates the first set, and is then relieved by the female, who has by that time finished her laying. The period of incubation is three months. The development has been recently studied by W. A. Haswell (Linn. Soc. New South Wales, 1887). The Spotted Emu, restricted to Western Australia, has often bred in captivity or attempted domestication in Britain and elsewhere.

**Emulsin**, or **SYNAPTASE**, is a peculiar ferment present in the bitter and sweet almond, which forms a constituent of all almond emulsions. When bitter almonds are bruised, and water added, the emulsin acts as a ferment on the amygdalin,

and decomposes the latter into volatile oil of bitter almonds, prussic acid, grape-sugar, and water (see **ALMONDS**, **VOLATILE OIL**). The vegetable albumen of almonds is almost entirely composed of emulsin, which, when separated, is a white substance, soluble in water, and is distinguished by its remarkable power of causing the fermentation of amygdalin. It consists of carbon, hydrogen, nitrogen, and oxygen.

**Emulsion** is the term applied to those preparations in pharmacy in which oleaginous substances are suspended in water by means of gum, sugar, carrageen, yolk of egg, &c. The production of these emulsions is often not an easy matter, and requires judgment and skill. In general it will be found that the bulk of the emulsifier must first be taken, while the oil should only be added little by little, rubbing together in a mortar, and taking care that it is completely absorbed or emulsified before further additions. Should too much be added, the effect is to throw out most of what has already been incorporated, and it is then almost impossible to remedy the error. The emulsion of cod-liver oil is probably known to all, but there are many emulsions in which solid substances have to be suspended, and to them the directions above given are not always applicable.

**Emys**, a genus of Marsh Tortoises, including *E. lutaria*, found in south and middle Europe, North Africa, and south-west Asia. The other species are oriental and American.

**Enamel** (Fr. *email*; originally *asmail*, from the same root as *smelt*), the name given to vitrified substances applied chiefly to the surface of metals. Enamelling is practised (1) for purposes of utility, as in making the dial-plates of watches and clocks, coating the insides of culinary vessels, &c.; and (2) for producing artistic designs, portraits, and for ornamental purposes generally. The basis of all enamels is an easily fusible colourless glass, to which the desired colour and opacity are imparted by mixtures of metallic oxides. The mass, after being fused together and cooled, is reduced to a fine powder and washed, and the raw material thus obtained is variously applied to the surfaces to be covered according to the class of enamel being made. The whole is then exposed in a furnace (*fired*, as it is called) till the enamel is melted, when it adheres firmly to the metal. The metal most commonly used as a ground for enamel is copper; but for the finest kinds of enamel-work gold and silver are also used.

**Artistic or Ornamental Enamelling**.—This art is of great antiquity; it was to a limited extent practised by the Greeks; but enamels were more largely employed by the Romans, under whose dominion the art passed into Gaul and Britain. Enamelling has also been practised from a remote period in the East, Persia, India, China, and Japan, under a separate and distinct development; but there is nothing from which it can be inferred that the various methods were in use earlier than in Europe. As a decoration enamelling was more popular and attained to greater perfection in the middle ages than in classic times. It was extensively practised at Byzantium from the 4th until the 11th century, and afterwards in Italy, in the Rhenish provinces, and at Limoges in the south of France. The Byzantine and other early styles of enamel-work, down to the 14th century, were generally employed in ornamenting objects connected with the service of the church. Enamel was also greatly used in ornamenting jewelry, and vessels made for use or display in the mansions of the rich, such as salt-cellars, coffers, ewers, candlesticks, &c.; but these objects were principally made in the painted

enamels introduced in France towards the end of the 15th century.

Distinguished with reference to the manner of execution, enamel-work may be divided into four kinds: (1) *Cloisonné*, or inclosed, the method of the Byzantine school, in which the design is formed in a kind of metal case, generally gold or copper, and the several colours are separated by very delicate filigree gold bands, to prevent them running into one another. Of this style the grandest example extant is the famous *Pala d'oro* in St Mark's Church, Venice, some portions of which are Byzantine of the 10th century. (2) *Champlevé*, practised by the Rhenish and early Limoges schools. In this process the ornamental design, or the figures which were to be filled in with colour, were cut in the metal (generally copper) to some depth; and wherever two colours met, a thin partition of the metal was left to prevent the colours running into each other by fusion when fired. (3) Translucent enamel, which had its origin and was brought to great perfection in Italy, was composed of transparent enamel of every variety of colour, laid in thin coatings over the design, which was incised on the metal, generally silver, the figure or figures being slightly raised in low relief, and marked with the graver, so as to allow the drawing of the contours to be seen through the ground, instead of being formed by the coarse lines of the copper, as in the early Limoges enamels. (4) Surface-painted enamels, which may be divided into two stages. The first stage, which is known as the late Limoges style, sprang up about 1475, and flourished till 1630. In this the practice was to cover the metal plate with a coating of dark enamel for shadows, and to paint on this with white, sometimes having the hands and other parts of the figures completely coloured. The designs of the middle and best period were generally taken from well-known paintings or engravings of the period, and were strongly influenced by the Italian art of the time. This style soon degenerated, and gave place to the latest or *miniature* style, which was invented before the middle of the 16th century by Jean Toutin, a goldsmith at Châteaudun, and carried to the highest perfection by Jean Petitot, a miniature-painter, who was born at Geneva, 1607, and resided long in England, and then in Paris. On his method the plate is covered with a white opaque enamel, and the colours are laid on this with a hair-pencil, and fixed by firing. The paints are prepared by grinding up coloured enamels with oil of spike, and when fused by the heat, they become incorporated with the enamel of the ground. The earlier enamellers of this school occupied themselves with miniatures, snuff-boxes, watch-cases, and other trinkets, till the period of the Revolution, when the art fell into disuse in France. In England, however, it was carried on with much success; and copies of portraits and pictures on a much larger scale than the French miniatures were executed by Henry Bone (1755-1834), and the German, Karl Müss (died 1824). Works of this description possess the obvious advantage of durability; but those various qualities of texture, and the delicacy of colour for which good works in oil or water-colour are prized, cannot be attained in enamel copies. The greater part of the artistic enamel-work of the present day is of Japanese fabrication, and consists of *elvisonné* work on a copper basin. Both in Paris and in Birmingham enamel-work of this class has been attempted with success; but designs can be executed in Japan at prices which defy the competition of western traders. In China both *cloisonné* and painted enamels are made in characteristic Chinese designs. At Jeypore in India a limited quantity of enamel-

work on gold is executed in translucent colours which possess incomparable brilliancy. Enamel incrustations of various kinds are very largely used in the jewelry, goldsmith, and silversmith trades of Europe. See Garnier, *Histoire de la Verrerie et de l'Émaillerie* (1886); Bowes, *Japanese Enamels* (1885); and for enamelled earthenware, see the article POTTERY.

*Enamelled Iron*.—Since the beginning of the 19th century many attempts have been made to cover iron with a vitreous surface, and several patents have been taken for such methods of enamelling. The chief difficulty in applying enamels to iron arises from the tendency of the metal to oxidise before it reaches the temperature at which the enamel fuses, and to become brittle from the oxide combining with the silica of the enamel. This action being superficial, the mischief is the greater in proportion to the thinness of the iron. Therefore it is much easier to enamel thick cast-iron vessels than thin vessels made of sheet-iron. A glass may be made by combining either silicic acid or boracic acid with a base; the latter fuses at a lower temperature than the former, but the glass is much dearer and not so durable as the silica glass. The enamels used for coating iron consist of a mixture of silica and borax, with various basic substances, such as soda, oxide of tin, alumina, oxide of lead, &c. Lead is not, or ought not to be, used in the enamel for coating culinary vessels.

A great variety of articles, many of them beautifully decorated in colours, such as grate-fronts, clock-dials, panels of different kinds, sign-boards, tablets, and name-plates, are now executed in enamelled iron at a moderate cost. It is also applied to corrugated roofing. The effect of heat on enamelled iron especially is to expand the metal more than the enamel, and cause the latter to peel off. Acids find their way through minute invisible pores, which exist in the best enamel; and when once they reach the iron, they rapidly spread between it and the enamel, and undermine and strip it off. This kind of action is curiously shown by filling an enamelled vessel with a solution of sulphate of copper. The acid attacks the iron wherever pores exist, and little beads of metallic copper are deposited at all such spots; these beads go on growing until they are large enough to be very plainly seen. This is the severest test for trying the continuity of enamelled surfaces to which they can be subjected, as sulphate of copper will penetrate the glaze and body of ordinary earthenware.

The enamel of teeth is the very hard translucent white layer covering the working surfaces of the Dentine (q.v.) or ivory of the teeth of most mammals. See TEETH.

**Enara**, a lake in the extreme north of Finland, with an area of 550 sq. m. and numerous islands. It discharges into the Arctic Ocean.

**Enarea**, or LIMMU, a kingdom of Africa, SW. of Shoa, with an area of over 1100 sq. m., and some 40,000 inhabitants. It is a land of forest-clad hills, rising beyond 8000 feet, with their slopes covered with the wild coffee-plant. Its people, belonging to a stem of the Gallas (q.v.), are mostly Mohammedans. The chief town is Saka, near the river Gibbe. See Cecchi, *Da Zeila alle Frontiere del Caffa*, vol. ii. (Rome, 1885).

**Encenia**. See COMMEMORATION.

**Encalada**, MANUEL BLANCO, born in Buenos Ayres in 1790, studied at Madrid and in the naval academy at Leon, and after deserting from the Spanish ranks, joined the Chilean revolutionary party, and served with distinction both in the artillery and in the navy. Appointed second to

Lord Cochrane, he became rear-admiral in 1819, and major-general of infantry in 1820; and in 1825 he was appointed head of the army of Chili. He was for two months president of the republic in 1826, governor of Valparaiso in 1847-52, and minister to France in 1853-58. He died in Santiago, 5th September 1876.

**Encampment.** See CAMP.

**Encaustic Tiles.** See TILES.

**Enceinte** (Fr.), in Fortification, denotes generally the whole area of a fortified place. See FORTIFICATION.

**Encephalartos.** See CYCADS.

**Encephalocele** (derived from the Greek *encephalon*, 'the brain, and *kēlē*, 'a tumour') is the term applied to a tumour projecting through the skull in one of the parts where the bones are incomplete in infancy, and consisting of a protrusion of the membranes of the brain, containing a portion of brain itself. In *meningocele* the membranes only project. The most common situation of such tumours is in the middle line and at the back of the head. Surgical interference is scarcely ever justifiable, and all that can usually be done is to give uniform support to the tumour, and to defend it from injury.

**Enchondroma** is the term employed in Pathological Anatomy to signify an abnormal cartilaginous growth. These growths most commonly occur in connection with the bones, but they are not unfrequent in some of the glandular structures. See TUMOURS.

**Enchina**, or ENZINA, JUAN DE LA, the founder of the secular drama in Spain, was born about 1409, not far from Salamanca, at the university of which town he was educated. He held successively the offices of secretary to the first Duke of Alva, musical director in Pope Leo X.'s chapel at Rome, and prior of Leon in Spain. He died at Salamanca in 1534. Besides his *Cancionero*, a collection of poems which went through six editions between 1496 and 1516, he wrote in 1521 a poor poetical account of a pilgrimage which he made to Jerusalem two years previously. But his fame rests on the fact that he wrote eleven dramatic poems (*Representaciones*), six of a religious cast, but the other five altogether secular, these last the first of the kind to be acted in Spain, in 1492. In themselves these pieces possess no great merit, being almost destitute of plot, and showing very little dramatic structure or spirit.

**Encke**, JOHANN FRANZ, astronomer, was born at Hamburg, September 23, 1791. After studying at Göttingen, he served, during the campaign of 1813-14, in the artillery of the Hanseatic legion, and in 1815 in the Prussian army, as lieutenant of artillery. On the establishment of peace he left the service, and became assistant, and afterwards principal astronomer, in the observatory of Seeberg, near Gotha. In 1825, chiefly at the instigation of Bessel, he was called to Berlin as secretary of the Academy of Sciences and director of the observatory. While at Gotha, the astronomical prize offered by Cotta was awarded to Encke by the judges Gauss and Olbers, for his determination of the orbit of the comet of 1830. This led him to solve another problem, which had been proposed along with the other—viz. the distance of the sun. The solution, by means of the two transits of Venus in 1761 and 1769, is published in two separate tracts (*Die Entfernung der Sonne*, Gotha, 1822-24). In 1819 he proved that the comet discovered by Pons, November 26, 1818, revolved in the hitherto incredibly short period of about 1200 days, and had been already observed in 1786, 1795, and 1805. It has since gone by

the name of Encke's comet, and has appeared regularly; the period of its recurrence being 3.20 years, or about  $3\frac{1}{5}$  years (see COMETS). Encke's researches on this subject are contained in the *Transactions of the Berlin Academy*. In 1830 he undertook to edit the *Berlin Astronomical Almanac*, in which he published a number of astronomical treatises (separately published, 3 vols. 1866). Four volumes appeared of his *Astronomical Observations at the Berlin Observatory* (1840-56). He died 2d September 1865. See his Life by Brühlus (Leip. 1869).

**Enclosures.** See COMMONS.

**Encore** ('again'), a French expression, generally used in England by the audience of a theatre or concert-room when requesting the repetition of the performance of a piece of music. It is not used by the French themselves, who, in similar circumstances, exclaim *bis* ('twice').

**Encratites.** See TATIAN.

**Encrinites**, fossil Crinoids, often known as stone-lilies. They occur very abundantly, and

Encrinite Stems (Mountain Limestone).

often seem as thick in a limestone or marble bed as straws in a corn-rick. See CRINOIDS.

**Encumbered Estates Court.** In 1840 a statute was passed to facilitate the sale of encumbered estates in Ireland, and constituting a court to which landlords of such estates might apply to direct the sale. Up till 1859 (when this court was superseded by the Landed Estates Court, dealing also with unencumbered estates) this court made 3457 sales, producing a sum of £25,100,839. See IRELAND.

**Encyclical** (*litera encyclicæ*), a letter addressed by the pope to all his bishops, condemning current errors or advising the Christian people how to act in regard to great public questions. It differs from a Bull (q.v.) mainly in that the latter is usually more special in its destination. The famous encyclical, *Quantum Cura*, issued 8th December 1864 by Pius IX., was accompanied by a *Syllabus* condemning specifically eighty errors in religion, philosophy, and politics.

**Encyclopædia** (from the Greek *enkyklios*, 'circular' or 'general,' and *paideia*, 'discipline' or 'instruction') is in modern usage a work professing to give information in regard to the whole circle of human knowledge, or in regard to everything included within some particular scientific or conventional division of it. The character of such works has of necessity varied from generation to generation, with changing conceptions of the scope and value of our knowledge and of the mutual relations of one department with another. An encyclopædia as such cannot rise above the general culture of its time; the medieval encyclopædia will be as medieval in the distribution and perspective of its subjects as in the selecting and presenting of its facts. As knowledge has increased it has become more and more necessary, in order to say something (and the most important something) about everything, to be content not to say everything about anything. And while, in the 16th century, one laborious student might undertake to give the world a conspectus of all that was of worth in its literature and science, a modern work of

similar scope demands the co-operation of hundreds of intellects. For the history of the word, see Boeckh's *Encyclopædie und Methodologie der phil. Wissenschaften* (1866, pp. 34-37).

Though several of the ancient philosophers of Greece, and notably Aristotle, carried their investigations into every department of inquiry within their intellectual horizon, none of them seems to have compiled exactly what we now call an encyclopædia. Spensippus, indeed, is credited with something of the sort; but his works exist only in fragments. The great Latin collections of Terentius Varro (*Recurum humanarum et divinarum Antiquitates* and *Disciplinarum libri ix.*), dating from 30 B.C., and the so-called *Historia Naturalis* of the elder Pliny (23-79 A.D.), may thus be considered as the first specimens of their class. The 5th century saw the production of a curious and oddly written encyclopædia by Martianus Capella; in the 7th, Isidorus Hispalensis compiled his *Originum seu Etymologiarum libri xx.*, which was afterwards abridged and recast by Hrabanus Maurus. Under the calif of Bagdad, Alfarabius or Farabi, in the 10th century, wrote an encyclopædic work, *Ihsa Aulum*—remarkable for its grasp and completeness; but this has hitherto been left in manuscript (a fine copy is preserved in the Escorial). Vincent of Beauvais (Vincentius Bellovacensis), who probably died in 1204, gathered together, under the patronage of Louis IX. of France, the entire knowledge of the middle ages in three comprehensive works—*Speculum Historiale*, *Speculum Naturale*, and *Speculum Doctrinale*, to which an unknown hand soon after added a *Speculum Morale*. About the same time Brunetto Latini was engaged on his *Liures dou Tresor* (printed in Italian in 1474, and in the original French in *Documents inédits*, 1860). The *De proprietatibus rerum* of Bartholomæus de Glanville deserves mention as being of English origin and highly successful in its day. Written about 1360, this became exceedingly popular in the translation (1398) by the Cornishman John Trevisa. In 1541 the name Cyclopædia is first used as the title of a book by Ringelberg of Basel, and in 1559 Paul Scalich styles his work *Encyclopædia seu orbis disciplinarum tum sacrarum tum profanarum*. Among the numerous encyclopædias of the 17th century it is enough to mention Antonio Zucca's (Venice, 1615) and Alsted's (7 vols. fol. Herborn, 1630), both in Latin; Moreri's *Grand Dictionnaire historique* (Lyons, 1674), which reached a 20th edition in 1759; Hofmann's *Lexicon Universale* (2 vols. fol. Basel, 1677; 4 vols. fol. Leyd. 1698), which was the first attempt to bring the whole body of science and art under the lexicographic form; Thomas Cornelle's *Dictionnaire des Arts et des Sciences* (2 vols. Paris, 1694; and most famous of all, Bayle's *Dictionnaire historique et critique* (4 vols. Rotterdam, 1697), which was mainly designed as corrective and supplementary to Moreri. This last appeared in several English editions generally more or less expurgated or modified, as in that issued at London (10 vols. fol. 1734-41); and J. G. de Chauvigné published a *Nouveau Dictionnaire* as a supplement (4 vols. Amsterdam, 1750). It was in the course of the 17th century that encyclopædists began regularly to employ the vulgar tongues for their work, and to arrange their material alphabetically for convenience of consultation. Of the vast *Bibliotheca Universale*, planned by Coronelli to fill 45 folio volumes, only a small portion saw the light (Venice, 1701-6). The series of great encyclopædic works in modern English practically began by the anonymous *Universal, Historical, Geographical, Chronological, and Classical Dictionary* (2 vols. 1703), and the *Lexicon Technicum* of Dr John Harris (Lond. 1704). Ephraim Chambers followed in 1728 with his *Cyclo-*

*pædia*, or an *Universal Dictionary of Arts and Sciences* (2 vols. fol.), which presents a distinct advance in the construction of such works, the author endeavouring to give to his alphabetically arranged materials something of the interest of a continuous discourse by a system of cross references. A sixth edition of this popular work appeared in 1751-52, and a supplement in 2 fol. vols. in 1753. Dennis de Coetlogon published *An Universal History of Arts and Sciences* (2 vols. fol. Lond. 1745). A revised and enlarged edition of Chambers's was published in 1778-88 by Abraham Rees, who, besides incorporating the supplement with the main body of the work, added a large amount of original matter.

It was a French translation, by John Mills, of Chambers's *Cyclopædia* which originally formed the basis of that famous *Encyclopédie* which, becoming in the hands of D'Alembert and Diderot the organ of the most advanced and revolutionary opinions of the time, was the object of the most violent persecution by the conservative party in church and state, and suffered egregious mutilations at the hands not only of hostile censors but of timorous printers. So thoroughly was it identified with the philosophic movement of the time that the term *Encyclopédiste* became the recognised designation of all attached to a certain form of philosophy. Appearing at Paris in 28 vols. between 1751 and 1772, it was followed by a supplement in 5 vols. (Amst. 1776-77), and an analytical index in 2 vols. (Paris, 1780). Voltaire's *Questions sur l'Encyclopédie* (1770) formed a kind of critical appendix. La Porte's *Esprit de l'Encyclopédie* (Paris, 1768) gave a résumé of the more important articles, and under the same title Hennequin compiled a similar epitome (Paris, 1822-23). Numerous editions of the whole work, more or less expurgated or recast, were issued outside of France; and many minor encyclopædias, such as Macquer's *Dictionnaire Portatif des Arts et Métiers* (1766), Barrow's *New and Universal Dictionary of Arts and Sciences* (1 vol. fol. 1743), and Croker, Williams, and Clerk's *Complete Dictionary of Arts and Sciences* (3 vols. fol. 1766), were to a considerable extent quarried out of their massive predecessor, or moulded according to the method expounded by D'Alembert in his preliminary dissertation. In 1780 a privilege was obtained by C. J. Panckoucke for the publication of an *Encyclopédie Méthodique, ou par Ordre des Matières*, which was at first intended to be little more than a rearrangement and supplementing of the matter of Diderot's work; each main subject having a separate 'dictionary' for itself. But its method was too much for it; the scheme, though 166 vols. had been issued by 1832, was never completely realised.

Between 1768 and 1771 there appeared at Edinburgh in 3 vols. 4to the first edition of the *Encyclopædia Britannica*, which was from the beginning a kind of compromise between the alphabetical and the scientific distribution of subjects. Colin Macfarquhar, Andrew Bell, and William Smellie share the credit of the plan. Biographical and historical articles were first introduced in the 2d edition (10 vols. 4to, 1776-1784). The third edition (18 vols.) was completed in 1797; the fourth (20 vols.) in 1810; the fifth, a mere reprint, in 1817. To the sixth edition (1823) Constable, the publisher, prefixed the well-known volume of preliminary dissertations by Dugald Stewart, Playfair, &c. The seventh edition, edited by Macvey Napier, was published by Messrs Black between 1830 and 1842. The eighth (21 vols. and index) appeared 1853-61, under the editorship of Dr Thomas Stewart Traill; and the ninth, edited by Professors Thomas S. Baynes and W. Robertson Smith, was completed in 24 vols. in 1875-88 (Index, 1889). This last

edition was issued in America both by its Scottish publishers and by a so-called 'piratic' firm which also brought out the *Encyclopædia Americana* (4 vols. 1833-39) for the purpose of giving additional information about matters of 'American' interest.

During the period that the *Encyclopædia Britannica* has thus been growing from edition to edition, numerous important encyclopædias have appeared in English—the *Edinburgh Encyclopædia* (18 vols. 1810-30), edited by Sir David Brewster; Wilkes's *Encyclopædia Londinensis* (24 vols. 4to, Lond. 1810-29); *Encyclopædia Perthensis* (23 vols. Edin. 1816), a striking proof of the energy of its compilers, Aitchison of Edinburgh and Morison of Perth; the *Encyclopædia Metropolitana* (30 vols. 1818-45), arranged, according to a philosophic plan by Coleridge, in four divisions: (1) pure sciences, (2) mixed and applied sciences, (3) biography and history, and (4) miscellaneous and lexicographic articles; the *Penny Cyclopædia*, edited by Charles Knight for the Society for the Diffusion of Useful Knowledge (29 vols. (2 supplemental) 1833-46); and the *English Cyclopædia* (22 vols. 1853-61; a synoptical index, 1862; four supp. vols. 1869-73), founded on the copyright of the *Penny Cyclopædia*, but rearranged into four divisions—viz. geography, natural history, biography, and arts and sciences. In spite of the value of much of its material, this last encyclopædia, like Panckoucke's vast enterprise and Coleridge's ingenious scheme, furnished another proof that no encyclopædia can well be thoroughly popular which is not executed on the plan of a single alphabet. It is partly their rigid adherence to this method that has given their success to the popular German encyclopædias.

The encyclopædia now known as Brockhaus's *Konversations-Lexikon*, which was started by Löbel at Leipzig in 1796, and passed into the hands of F. A. Brockhaus in 1808, gave a great impetus to the production of similar works. It is still one of the most popular of German encyclopædias (13th ed. illust. 16 vols. 1882-87; supp. 1887). Its principal rivals are Pierer's, and Meyer's *Konversations-Lexikon*. The former (Altenburg, 1822-36, 26 vols., with 14 supplemental vols. 1840-56) has somewhat lost ground as a work of general reference; while the latter has become in completeness and compression the best work of its kind (1st ed. 15 vols. Leip. 1857-60; 3d ed. 1874-78; 4th ed. 1883, &c.), a striking characteristic being the free use made of maps, tabular condensations, woodcuts, and lithographic illustrations. The Brockhaus *Lexikon* became the basis, more or less entirely, of encyclopædias in most of the civilised languages of Europe—*Encyclopædia Española* (Madrid, 1848-51); *Nuova Enciclopedia Popolare Italiana* (Turin, 1841-51); *Nordisk Konversations-Lexikon* (5 vols. Copenhagen, 1858-63; 3d edition, 1883, &c.); *Svenskt Konversations-Lexikon* (4 vols. Stockholm, 1845-51; since re-issued with supplements). Four English works were professedly founded on it—*Encyclopædia Americana* (14 vols. Phila. 1829-1846); *New American Cyclopædia* (16 vols. New York, 1858-64), edited by Ripley and Dana, and frequently quoted as Appleton's from the name of the publisher (new ed. 16 vols. 1873-76); the *Popular Cyclopædia* (7 vols. Glasgow, new ed. 1883); and *Chambers's Encyclopædia* (10 vols. Edin. 1860-68, edited by Dr Andrew Findlater; new ed. 10 vols., edited by David Patrick, 1888-92). In this, the new edition, *Chambers's Encyclopædia*, already the best-known book of its class in the English-speaking world, has been entirely recast and rewritten.

Other English cyclopædias that require mention are Colange, *National Encyclopædia* (New York, 1872, &c.); Johnson's *Illustrated Universal Cyclopædia* (4 vols. New York, 1874-78); the *Globe Cyclo-*

*pædia*, edited by Dr J. M. Ross (4to, 6 vols. Edin. 1879; afterwards issued in London under the title of *Students' Encyclopædia of Universal Knowledge*); Neek and Baird, *Iconographic Encyclopædia* (4 vols., 2 vols. plates, New York, 1860); Brand and Cox, *Dict. of Science, Lit., and Art* (3 vols. 1865-67; new ed. 1875); the *National Encyclopædia* (Lond. 1884, &c.); and Blackie's *Modern Cyclopædia* (8vo, Lond. 1889, &c.). Nor should we omit Larousse, *Grand Dict. du XIX<sup>e</sup> siècle* (4to, Paris, 1878); Chevreuil, *Grand Dict. illustré* (4to, Paris, 1883); and Dreyfus, *La Grande Encyclopédie* (4to, 1885, &c.). Parry's *Encyclopædia Cambrensis* (1862-63) is of interest.

Among all European encyclopædias (and a few only have been mentioned; for every leading language could furnish a list) one stands out as a unique example of protracted production. A defect inherent in the constitution of every large encyclopædia brought out in successive volumes is that, as regards literature and the progressive sciences, the earlier portions are passing out of date before the later portions have come into existence. This characteristic is almost caricatured in the famous *Allgemeine Encyclopädie der Wissenschaften und Künste*, which was originally undertaken by Professors Ersch and Gruber in 1818, and has since continued slowly to appear in three several sections of the alphabet up to the present time. There have already appeared some 170 volumes, many of them containing the most elaborate monographs on individual subjects to be found in literature. Even this work looks small when compared with the great Chinese cyclopædia in 5020 Chinese volumes (6100 general headings), printed at Peking in 1726 by command of the Emperor Kang-Hi. It was restricted to a hundred copies, one of which reached the British Museum in 1878.

An attempt to remedy the defect of protracted production has frequently led to the issue of supplemental volumes, planned so as to bring up the earlier articles to the same time-level as the later articles. And in more than one instance (notably Brockhaus's and Meyer's *Konversations-Lexikon*, and Appleton's *American Cyclopædia*) this has culminated in the issuing of an *Annual Cyclopædia* on the same general lines.

In contrast with the larger encyclopædias may be mentioned the modern attempts to boil down the circles of the sciences into portable form. Thus Brockhaus issued a *Kleineres Konversations-Lexikon* (4 vols. Leip. 1854-56; 4th ed. 2 vols. Leip. 1885); Meyer's *Konversations-Lexikon* is admirably epitomised in Meyer's *Handlexikon* (4th ed. 2 vols. Leip. 1888); and Spemann issues a pocket encyclopædia (Kürschner's) which is a model of compression. Similar English productions are Beeton's *Encyclopædia* (2 vols. 8vo, Lond. n.d.); Beeton's *Dictionary of Science* (8vo, Lond. n.d.); Champlin's *Young Folks' Cyclopædia of Common Things* (New York, 1879), with the English re-issue known as Cox's *Little Encyclopædia of Common Things* (8vo, Lond. 1882; 3d ed. 1884); Champlin's *Young Folks' Cyclopædia of Persons and Places* (1880); Hazell's *Annual Cyclopædic Record* (4th ed. 1889); Sampson Low's *Pocket Cyclopædia* (1889); Phillip's *Million of Facts* (8vo, 1836; and later without date).

*Special Encyclopædias*.—This class has naturally become more and more numerous; though in many cases the works are neither designated encyclopædia nor dictionary. A valuable series is Meyer's *Fach-Lexika* (general history, ancient history, philosophy, geography, &c.), which applies the method of the 'dictionary' to the treatment of individual subjects in separate volumes; thus differing from Lardner's *Cabinet Cyclopædia*, and the *Encyclopædia Metropolitana*, which were practically a series of treatises.

ADULTERATIONS.—Baudrimont, *Dict. des Altérations* (6th ed. 8vo, Paris, 1882).

AGRICULTURE.—London's *Encyclopædia of Agriculture* (8vo, Lond. 1828); Wilson, *Rural Cyclopædia* (4th ed. 1848); Morton (2 vols. Glasgow, 1855); Barral (French, Paris, 1888, &c., very full).

ANTHROPOLOGY.—Bertillon, *Dict. des Sciences Anthropologiques* (8vo, Paris, 1882 *et seq.*).

ARCHÆOLOGY OR ANTIQUITIES.—General: Buse (French, 12mo, Paris, 1880). Greek and Roman: Smith's *Dictionary* (3d ed. 1890-91); Darenberg and Saglio (French, 4to, Paris, 1877, &c.); Baumeister, *Denkmäler* (8vo, 3 vols. 1884-89). Christian: Smith (8vo, Lond. 1875-80); Martigny (French, 8vo, Paris, 1877); Kraus, *Realencyclopædie* (8vo, Freiburg, 1880, &c.). German: Goetinger, *Real-Lexikon* (8vo, Leip. 1882, &c.).

ARCHITECTURE.—Stuart (3 vols. 8vo, Lond. n.d.); Gwilt (8vo, Lond. 1842; new ed. 1867; revised by Papworth, 8vo, Lond. 1888); *Dict. of Arch.* (Arch. Publ. Soc. 4to, Lond. 1864-89); Viollet le Duc (10 vols. 8vo, Paris, 1838-68); Bosc (French, 4 vols. 8vo, Paris, 1876-80); Audsley, *Popular Dict. of Arch. and the Allied Arts* (Liverpool, 1878, &c.); Mothes, *Illustriertes Baulexikon* (4th ed. Leip. 1881, &c.).

ARTS, FINE.—*Dictionnaire de l'Académie des Beaux-arts* (Paris, 1858, &c.); Waldow, *Ill. Encyclopædie der graphischen Künste* (8vo, Leip. 1880, &c.); Bosc (French, 8vo, Paris, 1883); Müller, *Lexikon der Bildenden Künste* (Leip. 1883).

ASTRONOMY.—Herpin's *Dictionnaire* (8vo, Paris, 1875); Gretsche's *Lexikon* (8vo, Leip. 1882).

BIBLE.—Jones (1827); Smith (1860-63); Kitto (2d ed. 1870); Eadie (14th ed. 1873). See RELIGION.

BIBLIOGRAPHY. See that article.

BIOGRAPHY. See the special bibliography appended to that article.

BOTANY.—London, *Encyclopædia of Plants* (8vo, Lond. 1829); Endlicher, *Genera Plantarum* (8vo, 1836-40); Paxton, *Botanical Dictionary* (8vo, Lond. 1808); Ulrich, *Dictionary of Plants* (8vo, Leip. 1872); Baillon's *Dictionnaire* (4to, Paris, 1877-85); Lindley and Moore, *Treasury of Botany* (8vo, Lond. 1886); Engler and Prantl, *Pflanzenfamilien* (1887, &c.); Durand, *Index Generum* (8vo, 1889).

CHEMISTRY.—Liebig (German, 8vo, Brunswick, 1842-64); Muspratt (2 vols. Edin. 1858-60; German ed. 1889); Ure (Watt's ed. 1808-68, with several supplements); Fehling (8vo, Brunswick, 1874, &c.); Ladenburg (in Trevellet's great encyclopædia); Frey (French, Paris, 1882, &c.); Wurtz (now ed. 1889, &c.).

CHRONOLOGY.—Oettinger, *Monteur* (8vo, Dresden, 1866-68; supp. Leip. 1873-82); Woodward and Cates (1872); Dicken's *Dict. of Days* (8vo, 1881, &c.); Haydn, *Dict. of Dates* (18th ed. 1885); Mas-Latrie, *Trésor de Chronologie*, &c. (fol. Paris, 1889).

COMMERCE.—Haushofer, *Handlexikon* (8vo, Vienna, 1881); MacCulloch (new ed. 8vo, 1882); Simmond's *Dictionary* (1883); Sacré (French, 8vo, Paris, 1884).

COOKERY.—Cassell's *Dictionary* (8vo, 1880-81); Hensdell's *Encyclopædie* (8vo, Winterthur, 1883).

COSTUME.—Planché (2 vols. Lond. 1876-79); Kretschmer and Rohrbach (4to, Leip. 1882).

COUNCILS.—Feltier (8vo, Paris, 1847).

DRAMA.—J. O. Halliwell, *Dictionary of Old English Plays* (8vo, Lond. 1860); Oppenheim and Gettke, *Deutsche Theater-Lexikon* (8vo, Leip. 1886); W. D. Adams, *Dictionary of the Drama* (8vo, 1883); Pough's *Dictionnaire* (8vo, Paris, 1884).

EDUCATION.—Schmidt's *Encyclopædie* (8vo, Gotha, 1859-76; 2d ed. 1876, &c.); Buissan (French, 8vo, Paris, 1882-87); Kiddle and Schen's *Cyclopædia* (8vo, New York, 1883); Fletcher, *Sonnenschein's Cyclopædia* (8vo, Lond. 1889).

ENGINEERING.—Appleton's *Cyclopædia* (New York, 1852); Rankine, *Cyclopædia of Machine and Hand Tools* (fol. Lond. 1869); Cressy's *Encyclopædia* (8vo, Lond. 1872); Spon's *Dictionary* (11 vols. 8vo, Lond. 1874-81).

FURNITURE.—Havard, *Dictionnaire de l'Ameublement et de la Décoration* (4to, Paris, 1888, &c.).

GARDENING.—Miller's *Dictionary* (1733); London (8vo, Lond. 1822); Perring's *Lexikon* (8vo, Leip. 1882); *Dict. of Gardening: Practical Ency.* (illus. vol. i. large post. 4to, Lond. 1884); Vilmorin-Andrieux, *The Vegetable Garden* (8vo, Lond. 1885); Robinson, *Garden Cyclopædia* (2d ed. 1889).

GEOGRAPHY. See article GAZETTEER.

GEOLOGY. See NATURAL SCIENCES, *infra*.

HISTORY.—Lalaune, *Dict. Hist. de la France* (8vo, Paris, 1872); Bouillet, *Dictionnaire* (8vo, Paris, 1876); Hermann, *Lexikon* (8vo, Leip. 1882); Peter, *Lexikon der Gesch. des Alterthums* (8vo, Leip. 1882); Adams, *Manual of Hist. Literature* (8vo, New York, 1882); Grégoire's *Dictionnaire* (2d ed. 12mo, Paris, 1883); Cassell's *Dictionary of English History* (1884); J. C. Ridpath, *Cyclo. of Univ. History* (2 vols. in 3, Cincinnati, 1885); Herbst, *Ency. der neuen Geschichte* (Gotha, 1888).

HYGIENE.—Tardieu, *Dict.* (8vo, Paris, 1865; Blyth, *Dict.* (8vo, Lond. 1870).

INDIA.—Balfour (3d ed. Lond. 1885).

INDUSTRIES AND MANUFACTURES.—Laboulaye's *Dictionnaire* (1st ed. 8vo, Paris, 1847; 6th, 4 vols. 8vo, 1885); Uro's *Dictionary* (3 vols. new ed. 1860); Tomlinson (3 vols. new ed. 1867); Spon's *Encyclopædia* (8vo, Lond. 1879, &c.); Lami, *Dict. Encyclopédique* (8vo, Paris, 1881, &c.).

INSURANCE.—Walford's *Cyclopædia* (1871, &c.).

JOURNALISM.—Sell's *World's Press* (8vo, 1889).

KNIGHTHOOD, &c.—Haydn, *Book of Dignities* (1851); Maigne's *Dict.* (Paris, 1861); Genoullat's *Dict.* (Paris, 1862).

LAW.—Bouvier's *Dictionary* (14th ed. Phila. 1870); Holtzendorff, *Encyclopædie der Rechtswissenschaft* (2d ed. 8vo, Leip. 1876-77); Sweet's *Dictionary* (8vo, Lond. 1882); Wharton's *Dictionary* (8th ed. edited by Lely, 8vo, Lond. 1889).

LITERATURE.—English: Chambers's *Cyclopædia* (Edin. 1843; new ed. 2 vols. 1885); Allibone's *Critical Dictionary of English Literature* (1859-71); H. Morley's *Library of English Literature* (1876-81), and compare article BIBLIOGRAPHY. American: Duyckinck's *Cyclopædia* (8vo, Phila. 1877). General: Vapereau, *Dict. Universel des Littératures* (8vo, Paris, 1876).

MATERIA MEDICA.—Wahlruch (8vo, Lond. 1808); Dujardin Beaumetz's *Dictionnaire* (Paris, 1882, &c.). See the article PHARMACOPEIA.

MATHEMATICS.—Klugel's *Wörterbuch* (1803-31; supp. by Grünert, 1833-36); Montferrier's *Dictionnaire* (Paris, 1835-40); Hoffmann's *Wörterbuch* (8vo, Berlin, 1858); Sonnet (8vo, Paris, 1867).

MECHANICS. See ENGINEERING, *supra*.

MEDICINE.—Copland (8vo, Lond. 1858); Cooper's *Dict. of Pract. Surgery and Ency. of Surgical Science* (2 vols. 1861-72); Dunglison (8vo, Phila. 1874); Ziemssen, *Cyclopædia of the Practice of Medicine* (18 vols. Lond. 1875-81); Eulenburg, *Realencyclopædie* (Vienna, 1880-83, 13 Bde.; 2d ed. 1884, &c.); Dechambre, &c., *Dict. Ency. des Sciences Médicales* (8vo, Paris, since 1864 in progress); *The International Ency. of Surgery*, ed. by Dr Ashurst (6 vols. 1882, &c., Macmillan); Quain's *Dictionary* (8vo, Lond. 1882); Littré's *Dictionnaire* (15th ed. Paris, 1884); Tuson's edition of Colley's *Cyclopædia of Practical Receipts* (2 vols. Lond. 1884); Bouchut and Despres's *Dictionnaire* (8vo, Paris, 1885); Heath's *Dict. of Pract. Surgery* (2 vols. 8vo, Lond. 1886).

MILITARY SCIENCE.—Voyle, *Mil. Dict* (1876); Poten's *Handwörterbuch* (8vo, Bielefeld, 1877-80); Lacroix's *Encyclopædie* (8vo, Paris, 1880); Wilhelm, *Dict. and Gazetteer* (8vo, Phila. 1881); Chesnel, *Dict. Encycl.* (2 vols. 8vo, Paris, 1881).

MISSIONS.—Brown (3 vols. 8vo, Edin. 1854); Newcomb (8vo, New York, 1856).

MOHAMMEDANISM.—Hughes (8vo, Lond. 1885).

MUSIC.—Lichtenthal (8vo, Milan, 1826); Grove (8vo, Lond. 1878, &c.); Mendel, *Conversations-Lexikon* (2d ed. Berlin, 1881, &c.); Riemann (8vo, Leip. 1882); Bisson and Lagarte (8vo, Paris, 1884).

MYTHOLOGY.—Roman and Greek: Smith (3 vols. 1843-48); Roscher (8vo, Leip. 1884, &c.). General: Vollmer (8vo, Stutt. 1835).

NATURAL SCIENCES.—*Encyclopédie par Professeurs du Jardin du Roi* (68 vols. including plat., Strasbourg and Paris, 1816-30); Trevellet's *Encyclopædie*, a vast work, including Botany, Chemistry, &c., in course of publication.

NAVAL SCIENCE.—*Encyclopædia* (8vo, Phila. 1881).

PAINTING.—Satelet, *Dict. des Arts de Peinture, Sculpture* (6 vols. Paris, 1792); Champlin, *Cyclopædia of Painters and Painting* (4 vols. Lond. 1888).

PHILOLOGY.—B. Schmitz, *Encyclopædie der philolog. Studien der neu. Sprachen* (8vo, Leip. 1876); Boeckh, *Encyclopædie und Methodologie der philolog. Wissenschaften* (8vo, Leip. 1886); Körting, *Encyclopædie und*

*Method. der englischen Phil.* (8vo, Heilbronn, 1880), and *Encyclopædie und Method. der roman. Phil.* (8vo, Heilbronn, 1888); Gieber, *Grundriss der rom. Phil.* (8vo, Strassburg, 1888).

PHILOSOPHY.—Franck, *Dictionnaire* (8vo, Paris, 1875); Noack, *Handwörterbuch* (8vo, Leip. 1877-79); Fleming's *Vocabulary of Philosophy*, edited by Prof. Calderwood (8vo, Lond. 1887).

PHYSICAL SCIENCES.—Karsten (8vo, Leip. 1857); Rodwell's *Dictionary* (8vo, Lond. 1871); Lommel's *Lexikon* (8vo, Leip. 1882).

POLITICAL ECONOMY.—MacLeod (8vo, Lond. 1863); Boccardo, *Dizionario* (8vo, 1874, &c.); Say, *Dictionnaire des Finances* (8vo, Paris, 1883).

POLITICS.—Garnier Pagès, *Dict. Politique* (6th ed. 8vo, Paris, 1860); Block, *Dict. Gen. de la Politique* (2 vols. 8vo, Paris, 1863-64); *Dict. de l'Admin. Française* (8vo, Paris, 1877).

QUOTATIONS.—*Dictionary* (12mo, Lond. 1824); *Dict. Greek, Latin, and Modern Languages* (8vo, Lond. 1858); Hoyt and Ward, *Cyclopædia, English and Latin*, &c. (5th ed. 8vo, Lond. 1884); and works of a like kind by Riley (Bohn), Bartlett, Brewer, &c.

RELIGION AND THEOLOGY.—Schlenker's *Bibel-lexikon* (5 vols. Leip. 1868-75); Blunt's *Dictionary* (8vo, Lond. 1872); Lichtenberger, *Dict. des Sciences Religieuses* (8vo, Paris, 1877, &c.); Herzog, *Realencyklopædie* (22 vols. 8vo, Göttingen, 1854-66; new ed. by Herzog, Plitt, and Haack, 18 vols. 1877-88, greatly altered), Eng. ed. by Philip Schaff (8vo, Edin. 1883, &c., with supp.); Addis and Arnold, *A Catholic Dictionary* (8vo, Lond. 1884); Niehm's *Handwörterbuch der Biblischen Altertümer* (2 vols. Leip. 1884); Hagenbach's *Encyklopædie und Methodologie* (11th ed. by Kautsch, 1884); Rühiger's *Encyclopædia*, translated by Macpherson (8vo, 2 vols. 1884-85); *Encyclopædia of Living Divines*, by Schaff and Jackson (8vo, Edin. 1887); Benham, *Dictionary of Religion* (1887); Holtzmann and Zöpfel, *Lexikon* (2d ed. Leip. 1888).

RURAL SPORTS.—Blaine (8vo, Lond. 1840; new ed. 1870).

**Endemic** (from *en*, 'among,' and *dēmos*, 'the people'), a term applied to diseases which affect numbers of persons simultaneously, in such manner as to show a distinct connection with certain localities. Endemic diseases are usually spoken of as contrasted with Epidemic (q.v.) and Sporadic (q.v.); endemic indicating that a disease infests habitually the population within certain geographical limits, and also that it is incapable of being transferred or communicated beyond those limits; while, on the other hand, a disease is termed epidemic if it is transmitted without reference to locality, and sporadic if it occurs in isolated instances only. It should be mentioned, however, that it is quite possible for an endemic disease afterwards to become epidemic, and many of the best known forms of complaint, such as cholera, yellow fever, &c., have a well-defined local habitat or place of incubation, in which they originate and subsequently spread to surrounding districts. The theory, accordingly, of endemic diseases is, that they are in some way or other connected with the soil—the result of terrestrial influences, or *miasms*—of poisons generated within the earth, or near its surface, and diffused through the air, so as to be weakened in proportion to the distance from the source of the poison. Such poisons are always observed to be more virulent in summer than in winter—more dangerous at night, when the vapours are concentrated on the surface of the soil, than in the daytime—more abundant in the plains, and in close confined places, than at a certain degree of elevation—more easily carried in the direction of the wind than in the opposite—and very often arrested altogether by water, or by a belt of forest or other luxuriant vegetation. In all these particulars, *endemic* are different from *epidemic* diseases, which bear no very obvious relation to the soil, and are not observed to be considerably modified either by the prevailing winds or the period of the day or night at which exposure to their influence takes place.

The most marked type of an endemic disease is Ague (q.v.) or Intermittent Fever, which has all the habits mentioned above, and is so marked a degree a denizen of particular tracts of country as to lead to their being in some instances almost depopulated. Many places in Italy are a prey to the *aria rattiva* or *Malaria* (q.v.), as it is popularly called; and hence, no doubt, even more than for protection from human foes, the custom so prevalent in that country of building the villages on the tops of hills, so as to secure immunity from the poisonous vapours raised by the solar heat from the plains lying on either side at the base of the Apennines. Terrestrial *miasms*, or such poisons as generate endemic diseases, are usually found in the neighbourhood of marshy flats, or of uncultivated tracts of land at the confluence of rivers, or where a *delta*, or a wide channel subject to overflow, is formed at the upper end of a lake. In proportion, too, as the heat of the sun is greater, the tendency to malarious emanations is increased; and in the tropics, accordingly, large tracts of jungle and forest are often rendered absolutely uninhabitable and almost impassable at certain seasons by the invisible and odourless germs of intermittent, remittent, and even continued Fevers (q.v.), which are more fatal and unmanageable than the most terrible epidemic pestilences to those who are exposed to them. Such diseases are almost always sudden in their mode of attack, and they indicate the range of their influence by the number of persons attacked; but they are wholly free in most cases from the suspicion of communication by Contagion (q.v.), which is so frequent in the case of epidemic diseases. The precise nature of the malarious poison, though generally believed to be of the germ order, has never yet been discovered with any approach to exactness. It is known, however, to be almost invariably checked by drainage and cultivation of the soil; and hence many places in Europe, formerly very productive of endemic diseases such as ague, have now ceased to be so, as in the case of the Tuscan Maremma, and some parts of Kent and Essex, and of the Lothians in Scotland. The Eucalyptus-tree (*Eucalyptus globulus*) is said by several authorities to have a very beneficial influence on malarial districts, but this is a disputed point, and at best is probably quite as much due to the rapid growth and widespread nature of the roots of the Eucalyptus, which thus efficiently drain the soil, as to any effect produced by the essential oils given off in a vaporous condition from the branches.

**Enderby Land** lies in 65° 57' S. lat., 47° 20' E. long., discovered by John Briscoe in 1831, on a whaling voyage, and named in honour of his employer, Samuel Enderby, an adventurous London merchant, and the maternal grandfather of Chinese Gordon. His fleet of whalers first rounded the Horn, and actually opened up the Southern Ocean, discovered the Auckland Islands, and carried the first batch of convicts to Botany Bay. Briscoe, from stress of weather and extreme cold, could not approach Enderby Land within 20 or 30 miles, and was thus unable to say whether it was an island or a strip of continental coast.

**Endicott**, JOHN, colonial governor of Massachusetts, was born at Dorchester, England, in 1589, and landed as manager of the plantation of Nannkeag (Salem) in 1628. Giving place in 1630 to John Winthrop, he headed a sanguinary expedition against the Indians in 1636, was deputy-governor in 1641-44, 1650, and 1654, and governor in 1644, 1649, 1650-53, and 1655-65. Endicott was an austere Puritan, choleric, benevolent, and brave. He died at Boston, March 15, 1665.

**Endive** (*Cichorium Endivia*), an annual or biennial plant, of the same genus with Chicory (q.v.), has been in cultivation since classic times as a garden vegetable, its blanched leaves being much used as a salad. The green-curled variety is the staple one, the white-curled is good for summer and autumn, and the broad-leaved is used for tews and soups. In Britain the seed is usually sown from the middle of May to the end of June, and by a little care and protection plants may be kept fit for use throughout most of the winter.

**Endlicher**, STEPHEN LADISLAS, a systematic botanist, was born in Hungary, June 24, 1804. He was destined for the priesthood, but in 1827 commenced botanical and linguistic studies, and in 1840 he became professor of Botany in Vienna. Much disturbed by the events of 1848, he fell into melancholy, and in 1849 put an end to his own life. His *Genera Plantarum* (1836-40) has had great influence on succeeding botanists.

**Endocarditis**, disease of the internal surface of the heart, resulting in the deposit of fibrin upon the valves. See HEART (DISEASES OF).

**Endocarp**. See FRUIT.

**Endoderm**. See EMBRYOLOGY.

**Endogamy**. See MARRIAGE.

**Endogenous Plants**, or ENDOGENS, a name applied by Lindley to monocotyledons to express an erroneous view of the difference in their usual mode of stem-thickening from that of dicotyledons, and now wholly disused by botanists. See MONOCOTYLEDONS; also DICOTYLEDONS, BARK.

**Endomorph** is the name given to a mineral which is inclosed within another mineral, the latter being termed a *perimorph*. Such inclusions are very common in the constituent minerals of crystalline siliceous and igneous rocks.

**Endophagy**. See CANNIBALISM.

**Endophyte**. See ENTOPHYTE.

**Endor**, a village of Palestine, 4 miles S. of Tabor, now a poor mud hamlet, was the place which Saul visited (1 Sam. xxviii. 7) to consult the 'woman with a familiar spirit' previous to his fatal engagement with the Philistines.

**Endosmose**. See OSMOSE.

**Endymion**, a youth in Greek Mythology, celebrated for his beauty and his perpetual sleep. As he slept on Mount Latmos, in Caria, his beauty warmed the cold heart of Selēnē (the moon), who came down to kiss him and lie by his side. Different reasons were given for his sleep, the most general as well as the most poetic being that Selēnē had sent him to sleep that she might kiss him without his knowing. The story inspired the fresh fancy of the young Keats, who shaped it into an imperishable poem.

**Enéma**. See CLYSTER.

**Enemy**. According to the doctrine of the civil law, as formulated by Ulpian (Digest 49. 15, 24), those alone are enemies 'who have publicly declared war against us or we against them; all others are thieves and robbers.' In the earlier ages of the Roman republic such a declaration was most solemnly made to the foreign state by the *feciales* or priests, who acted as guardians of public faith, and was always attended by elaborate religious rites. So now, in order to constitute an enemy, there must be a public declaration of war made by a duly organised state or kingdom. Jurists are, however, divided in opinion in respect to the necessity of a previous declaration to the enemy in the case of an offensive war. Grotius and Vattel recommend such a previous declaration of war to the enemy, as being required by justice and humanity, and the latter specially commends

the *fecial law* of the Romans, as giving a sanction and solemnity to acts of belligerency. Bynkershoek, on the other hand, maintains that such a declaration is not required by the law of nations, and that, though it may very properly be made, it cannot be demanded as a matter of right. Since the time of Bynkershoek the practice of a solemn declaration made to the enemy has fallen into disuse, and the nation now contents itself with making a public proclamation of war within its own territory and to its own people. Some such formal public act is necessary to announce to the people at home their new relations and duties growing out of a state of war, and to apprise neutral nations of the facts, in order that they may conform their conduct to the new state of things. Under the British constitution, the sovereign alone declares war, but this prerogative of the crown is practically ineffectual, since, without the consent of parliament, the money requisite to carry on the war cannot be raised. It is still an open question whether war can be jurally waged by states only in their corporate capacity and with their corporate resources, or whether it embraces the individual members of the states at war, and the property which belongs to them as private persons. The tide of modern opinion, however, seems to have set in the direction of the former and more humane theory. The doctrine of the older jurists was that, on the formal declaration of hostilities, all the subjects of the one nation became enemies to all the subjects of the other. From this principle there has been deduced the important consequence, as a recognised rule of international law, that the property of alien enemies residing in either of the hostile states, may be confiscated, and even that such persons may be detained as prisoners of war. The Americans, during the war with England, asserted this right in regard to British property found in their territory. But the usage of civilised nations for a long period has much modified the stern rule of law. It is provided in Magna Charta that, upon the breaking out of war, foreign merchants found in England, and belonging to the country of the enemy, should be attached 'without harm of body or goods,' until it should be known how English merchants were treated by the enemy; 'and if our merchants,' said the charter, 'be safe and well treated there, theirs shall be likewise with us.' The statute of staples, 27 Edw. III. chap. 17, made a still more liberal and precise enactment in favour of such foreign merchants residing in England. Forty days were allowed them, after the proclamation of war, to remove from the kingdom themselves and their goods, and if by reason of accident that time were not enough, forty days more were to be conceded to them. Vattel, among others, denounces the practice of confiscating the goods of alien enemies, and maintains that a state, having permitted foreigners to enter its territory, and to continue there, has tacitly promised them full liberty and security for their return. In modern times it has become the usual practice of nations thus to respect the property of individuals on the outbreak of war. Stipulations to this effect are an established *formula* in all commercial treaties, and, even when there is no treaty, such a liberal provision is often announced in the declaration of war itself.

According to ancient usage, the utmost cruelty was lawful towards enemies. In modern times more humane principles prevail, and men recognise that, by taking up arms against one another in public war, they do not cease on this account to be moral beings, and responsible to one another and to God. Warfare is now carried on subject to certain general rules, which are intended, as much as may be, to abridge the calamities of war, and to protect

the rights of individuals. An admirable summary of these rules may be found in the Instructions for United States Armies, issued in 1863. These instructions were prepared by the celebrated jurist Francis Lieber, and have served as a basis for most of the subsequent compilations. In 1874 an International Conference held in Brussels devoted much time to the elaboration of rules for military warfare. Still more recently, the Institute of International Law, at its meeting at Oxford in 1880, prepared and adopted a *Manual of the Laws of War on Land*, in which minute rules for the conduct of hostilities are succinctly set forth. Military necessity admits of all direct destruction of life or limb of armed enemies, and of other persons where destruction is unavoidable in the armed contests of the war; it allows of all destruction of property, and obstruction of the ways and channels of traffic, and of all withholding of sustenance or means of life from the enemy. Such military necessity does not, however, admit of cruelty—i.e. the infliction of suffering for the sake of suffering, nor of maiming or wounding except in fight, nor of the use of poison in any way, nor of the wanton devastation of a district. It admits of deception, but disclaims all acts of perfidy. In the case of the occupation of a country by the enemy, the persons of the inhabitants, especially of women, are respected, and the maxims of religion and morality are acknowledged. Private property, unless forfeited by crimes, can be seized only on the ground of military necessity, and if the proprietor has not fled receipts are usually given, which enable the spoliated owner to obtain indemnity. Trade between the subjects of two hostile powers is absolutely suspended during hostilities, unless permitted by express sanction, and the importation of articles particularly useful in war is contraband. All such material, whether supplied by subjects of the enemy or of another state, is seized and confiscated. For other information on the rules and usages which regulate the relations of belligerent states, reference is made to the articles CONTRABAND OF WAR, BLOCKADE, NEUTRALITY, PRIZE, PRISONERS OF WAR, GENEVA, &c. As to the right of individuals to fit out vessels for the annoyance of the enemy, see PRIVATEER, and PIRACY.

Grotius, *De Jure Belli et Pacis*, lib. iii. chap. 3-7; Kent's *Commentaries*, vol. i. chap. 3; Bluntschli, *Das moderne Völkerrecht*; Sir Travers Twiss, *Law of Nations in Time of War* (Oxf. Clarendon Press, 2d ed. 1875).

**Energumen.** See DEMONOLOGY.

**Energy.** The term *energy* as applied to a material system is used to denote the power of doing work which is possessed by that system. There is no manifestation of energy apart from matter. In consequence of this, matter is sometimes defined as the vehicle or receptacle of energy. A bullet projected vertically upwards possesses a great amount of energy; it can do work in overcoming obstacles to its motion. But the higher it rises the less resistance can it overcome; and at last, having reached the greatest height it can attain, it seems incapable of doing work. Yet it is not really incapable of doing work. It will gradually acquire speed in the downward direction, and will finally (the resistance of the air being neglected) reach the ground with the same speed as it had at first, and is thus capable of doing the same amount of work. Therefore, when at its highest position and seemingly incapable of doing work, it really possessed energy as at first. Hence we are led to recognise two leading types of energy—energy of *motion* and energy of *position*; or, as they are usually called, *kinetic* energy and *potential* energy. We have many examples in nature of

both types. Currents of air or of water possess kinetic energy; a stone resting on the brow of a cliff, and water at the edge of a fall, possess potential energy.

But although energy may be classed under one or other of these two types, there are many forms in which it is manifested. There is energy of *visible motion* and energy of position in *visible arrangements* of bodies, as in the bullet moving upwards or downwards, or at rest at its highest position. A bent spring evidently possesses potential energy. An oscillating pendulum possesses alternately kinetic energy and potential energy. At the extremity of its swing the energy is entirely potential; at the middle of its range the energy is entirely kinetic; at intermediate positions it is partly of one kind, partly of the other. *Heat* is another form of energy. The particles of a hot body are in rapid motion, and the hotter the body the more rapid is the motion. The motion is on an invisibly small scale, but it can be communicated to other matter in such a way as to produce visible motion. Thus the invisible motions which constitute heat are applied in the steam-engine or air-engine to produce visible motion of a piston, and so to perform mechanical work. When Heat (q.v.) becomes *latent* in a body, part at least of the energy is spent in overcoming molecular forces, and the relative distances of the molecules of the body are altered; and so we have potential energy stored up in the molecules. Again we have the so-called *radiant energy*—energy propagated by means of undulations through the ether. This includes light as well as radiant heat, the two differing merely as regards wave-length. So also it includes the electro-magnetic undulations recently experimentally demonstrated by Hertz, the wave-length of which may be many feet instead of  $\frac{1}{100000}$  of an inch as in orange-coloured light. The vibrations of the particles of a hot or luminous body are communicated to the ether, and propagated by wave-motion through it at the rate of 186,000 miles per second. In the ether, therefore, the energy is partly potential, partly kinetic (see ETHER). There is also energy of *chemical separation*. Carbon and oxygen combine in the burning of ordinary fuel, and the energy which they contain in their separated state is used to produce mechanical work, as in the steam-engine; and in the explosion of gunpowder visible energy of motion is produced even more directly from the energy of chemical separation of the constituent substances. We have also potential energy of *electrical separation*, for if two conductors be charged with electricity, one positively and the other negatively, an attraction between them becomes apparent. In approaching each other the charged bodies can be made to do work. Again, when we have *electricity in motion* in a conductor, we have another means of producing work. The current of electricity produces heat and also tends to produce motion of other conductors in which electric currents flow. The attraction or repulsion between magnets can also be made to produce work, and so also we can get work from the mutual action between magnetised bodies and conductors in which electric currents flow.

Thus we see that energy may be manifested to us in a number of different forms; but as we do not yet know the ultimate nature of matter or of electricity, we cannot assert that the forms which we have just considered are all essentially distinct. It is not impossible that the energy of chemical separation is due to electrical separation, or that energy resulting from magnetisation is due to motion of electricity.

In the above remarks we have spoken not only of the production of work from energy, but of the

production of one form of energy from another, and of the passage of potential energy into kinetic energy. This change of energy from one form to another is known as the *Transformation of Energy*, and distinguishes it from matter. While matter is passive or inert, energy is continually in process of transformation—indeed we are cognisant of energy only in virtue of its change. We should never know that a moving cannon-ball possessed energy if we did not see its destructive effects; we should never know that electrified clouds possessed energy did we not see damage done by lightning.

Of the transformation of energy a few examples must suffice. We cause carbon and oxygen to combine in the furnace of a steam-boiler, or hydrogen and oxygen to combine in the cylinder of a gas-engine. This produces invisible motion of molecules, which in turn produces visible mechanical motion of the piston and connected mechanism. This motion may be communicated to a 'dynamo,' causing conducting wires to move in a magnetic field. Thus electric currents are produced in the wires. These currents may produce heat in, and cause radiation from, a highly resisting carbon filament. Or they may produce magnetic effects, and finally mechanical motion, in a motor. Thus energy may be applied by means of the dynamo and motor to the production of mechanical work in a place where it would not be easy to use an engine directly.

In the case of the telephone, the condensations and rarefactions of the air (which produce sound when they impinge on the ear) cause vibrations of the telephone diaphragm. As this motion occurs in the near neighbourhood of the pole of a magnet, electric currents of varying intensity and direction are produced in a coil of wire surrounding the pole. These currents pass round the magnet of the receiving telephone, and produce magnetic effects similar to those occurring at the sending instrument. Therefore similar mechanical effects are caused, and so like sounds are heard.

In the voltaic battery energy of chemical separation is transformed into energy of current electricity. The electric current may be passed through slightly acidulated water. The water is thus broken up into its constituents, so that energy of chemical separation is again obtained.

Many other examples of the transformation of energy might be given, but it is sufficient to remark that any form can be directly or indirectly transformed into any other form. A matter of greatest importance to us is the determination of the sources or source from which ultimately we derive mechanical work. The work obtained from animal labour is derived from the chemical energy of the food supplied to the animal. This food is vegetable food either actually or ultimately; for, even if it be actually animal, the energy of such food is ultimately traceable to the vegetable world. Now all vegetables grow by means of solar radiation, which decomposes carbonic acid in their tissues, so that energy obtained from animal labour is obtained actually from the sun. And if we use fuel in an engine, the energy of the fuel is in the same way due to the sun. If we use wind-power to drive our machines, the energy is also solar, for it is the sun which causes the atmospheric currents. So also the work obtainable from moving water, except in the case of tidal currents, is due to the heat radiated from the sun. Thus the sun is the great source of our energy; and, if he ceased to supply us with it, we could no longer produce work, except indeed in so far as he has already supplied us with a store in potential forms.

We have already stated that the energy of a material system is sometimes exhibited in one form, sometimes in another, but this statement

may be greatly extended. If no energy leaves the system, and if no new energy enters it, the quantity which disappears from one form reappears entirely in another. This is known as the principle of the *Conservation of Energy*. In the case of the bullet projected upwards, the potential energy in the highest position would be the exact equivalent of the original kinetic energy, if none were communicated to the air or other bodies. The same would hold in the case of the pendulum, if no energy were given from the system to the air or the supporting arrangement. [At one time the expression conservation of *force* was used instead of conservation of *energy*, but the word 'force' meant then what we now call 'energy.' The conservation of force, as we now use the word, means something totally different. See FORCE.]

The law of conservation of energy may be stated as follows: The total amount of energy in a material system cannot be varied, provided the system neither parts with energy to other bodies nor receives it from them. This law is merely a generalisation from observed facts; a single known exception would cause us to abandon or modify the statement. But the amount of positive proof in favour of the law is now exceedingly great, perhaps the strongest proof being afforded by the accuracy of scientific predictions founded upon the assumption of its truth. As an example, we may refer to the prediction of the lowering of the freezing-point of water by pressure. The assertion of the principle of conservation of energy is equivalent to a denial of the possibility of the 'Perpetual Motion' (q.v.).

In a scholium to his third law of motion, Newton asserts that 'if the action of an external agent is estimated by the product of its force into its velocity, and the reaction of the resistance in the same way by the product of the velocity of each part of the system into the resisting force, arising from friction, cohesion, weight, and acceleration, the action and reaction will be equal to each other, whatever be the nature and motion of the system.' Now the product of a force into the velocity produced by it is simply the rate at which the force does work. Hence, as was first pointed out by Thomson and Tait in their work on *Natural Philosophy*, this statement of Newton's is almost a complete statement of the principle of conservation of energy. Newton did not know what becomes of work spent in overcoming friction; he believed that it disappeared from the system. Had he known that it was converted into an exact equivalent in the form of heat, his statement would have been complete. It was not until long after Newton's time that Heat (q.v.) was recognised to be a form of energy. The experiments of Rumford and Davy first led to this result. Rumford's experiments were made in 1798 and 1799, on the work done, and the heat produced, in the boring of cannon. He concluded that heat must be due to motion. Davy's experiments on the melting of ice by friction were also made about the same time, but it was not until 1812 that he came to the conclusion that 'the immediate cause of the phenomenon of heat is motion, and the laws of its communication are precisely the same as the laws of the communication of motion.' From data given by Rumford, it may be calculated that 940 foot-pounds of work are necessary to produce heat sufficient to raise the temperature of one pound of water by 1° F.—the foot-pound being the work done in raising a pound through one foot against gravity. The researches of Colding and Joule, however, have given a far better determination of the mechanical equivalent of heat; and Joule's experiments, especially, extend to all forms of energy, and prove their exact

equivalence. His experiments on the heating of water by friction gave results varying from 770 to 774 foot-pounds as the *mechanical equivalent* of heat. His final result was 772, the possible error being much less than 1 per cent. Many indirect methods have also been used by Joule and others. Thus, the mechanical equivalent may be directly determined by observing the quantity of heat developed during the passage of an electric current of known intensity through a conducting wire of known resistance. The result for heat being assumed, it is easy to find the work-equivalent of other forms of energy. Thus, we can determine the equivalent in work of the energy of chemical separation—e.g. by dissolving zinc in sulphuric acid, and observing the heat developed. If the zinc be dissolved in a voltaic cell which is producing a current, heat is evolved in the various parts of the circuit in proportion to their resistance. Thus, by placing in the circuit a wire of great resistance, almost all the heat will be developed in the wire, and so may readily be measured. Again, by making the current produce work through the agency of an electro-magnetic engine, the work may be directly measured, care being had to take account of energy lost in the process by friction or otherwise. Less heat is developed in the circuit in proportion as the work done is greater, the total energy being constant. So, by expending work in driving a magneto-electric machine, we may find the work-equivalent of electric energy. As the electric energy ultimately becomes heat, Joule used this method in one of his determinations of the quantity of heat produced from a known amount of work.

We have seen that we can neither increase nor diminish the total quantity of energy in the universe, while any one form of it may be changed into any other; but we have made no inquiry as to whether or not all forms are equally transformable. The question is obviously of vital importance to us; for, if one form be less transformable than the rest, when we change any other kind into this one, we shall not be able completely to re-transform it. Thus there will be a tendency for all forms to be reduced to this more permanent form, and we shall not be able so readily to obtain mechanical work from it. Sir W. Thomson first pointed out that there is in nature a universal tendency to this *Dissipation* (or, as it has since, and perhaps preferably, been called *Degradation*) of *Energy*. The final form which all energy tends to take is that of heat. But heat tends continually to diffuse so as to equalise temperature; and, when there is no difference of temperature between the source and condenser of a heat-engine, no work can be obtained from it, for the amount of work which can be obtained from a given quantity,  $H$ , of

heat (see HEAT) is  $JH \frac{T - T_0}{T}$ .  $T$  and  $T_0$  being the absolute temperatures of the source and condenser respectively, while  $J$  is the mechanical equivalent of heat. Obviously  $JH \frac{T_0}{T}$  is the quantity of energy

lost for useful purposes so far as this engine is concerned. This shows that all the amount of heat supplied cannot be transformed into work, unless the condenser be at the absolute zero of temperature. If we take as our source of heat in one case a cubic foot of some metal at a given absolute temperature, and in another case two cubic feet of the same metal containing together the same quantity of heat as the one cubic foot formerly contained, and therefore at half the temperature provided the specific heat be constant, it is obvious, from the above expression, that twice as much heat will be lost in the second case as in the first. Hence, we see that heat at low temperature is much less use-

ful than the same quantity of heat at high temperature. And a corresponding statement is true for other forms of energy. Thus, if we have two Leyden jars alike in every respect, and charge one with a certain quantity of electricity, we can get a certain amount of work from the arrangement, which is made evident by the loudness of the sound and the brightness of the flash on discharge. But if we first divide the original charge between the two jars, and then discharge them, we can only get half the amount of energy. The reason is that the potential is only one-half of what it was in the first case; and the higher the potential of a given quantity of electricity is, the greater is the amount of work it can do, just as the usefulness of heat depends upon temperature. In fact, if  $V$  be the potential of the charge  $E$  in the first case,  $\frac{1}{2} VE$  is the energy; but in the second case the charge of each jar is  $\frac{1}{2} E$ , and the potential of each is  $\frac{1}{2} V$ , so that the energy in each is  $\frac{1}{4} VE$ , the total amount being therefore  $\frac{1}{2} VE$ , or only half of the original energy. The remaining half is accounted for by the energy spent in dividing the charge—light, sound, and heat being produced. Again, work may be obtained by letting compressed gas expand; and the amount of work depends upon the pressure. The gas may be allowed to expand without doing work, but energy will be dissipated, for the expanded gas, being at less pressure, cannot do so much work as it could do before expansion.

Examples of the degradation of energy are everywhere seen in nature. The fact that the optical image of a body is less distinct than the object itself is due to the fact that some of the so-called radiant energy is absorbed by the reflector, and takes the form of heat. The vibrations of a tuning-fork die down because the energy is communicated to the surrounding air, but they also diminish because of the production of heat from molecular friction in the vibrating body. The stilling of storms is accompanied by dissipation of energy. Possibly starlight is weakened in its passage through the ether. Indeed, no instance of transformation of energy can be pointed out in which there is not also dissipation of energy.

As we have already remarked, since all forms of energy tend to take the form of heat, and since heat is constantly tending by conduction and otherwise to equality of temperature, it follows that, unless the universe be infinite, energy will ultimately become useless for the production of work. The total amount of energy will, in accordance with the principle of conservation, be the same as at first, but any transformation of it will be impossible. There are two ways in which we may regard the energy of a given system; we may regard it from without the system, or from within. When we speak of the total energy of a system, we regard it from the outside. Thus, if we consider a thermal system, the total energy is the work which could be done by the heat in passing from the system to its surroundings, these being supposed to be constantly at the absolute zero of temperature. But the available energy (called in this case the *thermo-dynamic motivity*) is usually regarded as the greatest amount of work which can be obtained by equalising the temperatures of its various parts amongst themselves. [The motivity might, of course, also be regarded from without. In this case it would be the quantity of work obtainable by reducing all the parts of the system to some definite temperature.] The available energy of the universe, supposed finite, will therefore ultimately be zero. The energy of relative motion of its parts tends, in virtue of friction, to take the form of heat. Though we have no direct confirmation of the statement, yet we may conclude from analogy that the relative

motion of the planets and of all heavenly bodies tends to cease. Thus, ultimately, potential energy of gravitating matter must become kinetic energy of visible motion, and then heat; so that the universe will at last contain only one huge material body rotating about its centre of inertia, and the rotation too must cease in time. And even the molecular motions must largely cease, being communicated to the ether. All this is, of course, pure speculation. We might even, if we considered it profitable, speculate further with Rankine and others as to the possibility of the restoration of the availability of energy. If the universe be finite we may have reflection of radiant energy from its boundaries. A material body coming into a focus might be instantly vaporized, the radiant energy becoming again high-temperature heat.

The second law of thermo-dynamics (see HEAT) is essentially a statement, for the case of heat and mechanical work, of the principle of the dissipation of energy. Its proof, as given by Sir W. Thomson, depends upon the assumption that we cannot produce work from heat which is entirely derived from the colder of two bodies used as the source and condenser of a heat-engine. On an excessively small scale heat does pass in nature from a cold part of a body to a hot part, so as to increase the difference of temperature. In an excessively small portion of a gas, the quicker moving particles may be found in one part and the slower moving particles in another, even although the motion was uniform at first. Similarly, by moving in portions of the sides of a vessel containing gas when no particles were impinging upon them, we could increase the motivity of the system without doing work. As this is practically impossible, we see that the truth of the second law of thermo-dynamics depends essentially upon the extreme smallness and the great number of the particles of a body; so that, in the case of the gas, the motivity is increased only because work is done in compressing the gas which takes the form of heat, and is then removed from the system. Thus, while there is increase of motivity of the energy of the system, there is degradation of external energy.

If at any instant the motion of every particle of matter in the physical universe were reversed, the dissipation of energy would cease. Available energy would increase, for everything would occur over again exactly as in past time, but in the reverse order. This increase of availability would, however, only last until the configuration which existed at the commencement of the present order of things was reached, when dissipation of energy would again occur. This reversal of motion might occur in a system containing a very few particles, but we must regard it as an impossibility in the physical universe as a whole.

See the articles in the present work on HEAT, LIGHT, ELECTRICITY, &c., as also FUEL, &c., and for Muscular Energy, see DIGESTION. On the subject of the preceding article, *Tait's Recent Advances in Physical Science* (1876) may be consulted, and the same author's *Thermo-dynamics* (1877); Balfour Stewart's *Conservation of Energy* (1880); and the relevant portions of Clerk Maxwell's *Heat* (1875).

**Enfantin**, BARTHÉLEMY PROSPER, one of the chief representatives of the Saint-Simon school of Socialism, was the son of a banker in Paris, where he was born 8th February 1796. He went to the Ecole Polytechnique in 1812, but having joined the pupils who left school and fought against the allies on the heights of Montmartre and St Chaumont, he was expelled in 1814. Enfantin saw Saint-Simon only once, and apparently did not join the school till the death of the master in 1826. After the July revolution of 1830 Enfantin associated himself with Bazard for the active propagation of Saint-Simonism. Bazard expounded it in its relations

to philosophy and politics; Enfantin mainly in its relations to the social state. Soon, however, a schism broke out between the two on the question of marriage and the relation of the sexes. Enfantin recognised two sorts of marriage, one permanent, to suit steady and constant temperaments, the other changing and temporary, to suit the lively and mobile. A theory so subversive of social order led to the intervention of the government. The 'Supreme Father' (as his disciples were wont profanely to call him) was, in 1832, sentenced to two years' imprisonment and to pay a fine of 100 francs. Being released at the expiration of a few months, Enfantin went to Egypt for a time. He was subsequently appointed a member of the Scientific Commission for Algiers, and on his return from Africa wrote a sensible, interesting book, entitled *Colonisation de l'Algérie* (Paris, 1843). After the revolution of 1848 he edited the journal entitled *Le Crédit Public*. He afterwards held an important situation on the Lyons and Mediterranean Railway. He died August 31, 1864. That Enfantin was endowed with very extraordinary powers of fascinating and managing men is shown by the influence he exercised over a numerous body of clever and enthusiastic disciples. His plans for the construction of the Suez Canal paved the way for the great project since realised by Lesseps. The principal works of Enfantin are his *Doctrine de Saint-Simon*, in conjunction with others (1830); his *Traité d'Economie Politique* (1831); *La Religion Saint-Simonienne* (1831). An edition of the collected works of Saint-Simon and Enfantin, begun in Paris (1865), has now reached a large number of volumes.

**Enfocottment.** See FROFFMENT.

**Enfield**, a village of Middlesex, 12 miles by rail N. of London, with a population (1881) of 19,104, is the seat of a government small-arms factory, which is capable of turning out 5000 rifles a week; the ordinary weekly output is, however, about 1800.

**Engadine**, a famous valley in the Swiss canton of the Grisons, and one of the loftiest inhabited regions in Europe, extends north-east for about 65 miles along the banks of the Inn and its lakes, from the foot of Mount Maloja to the village of Martinsbruck. It is divided into two portions—that toward the south-west, called the Upper Engadine, and that toward the north-east, the Lower Engadine. The latter is the more wild and bleak; but the Upper Engadine, although it is more open, and possesses fine meadow-lands, has also an inclement climate throughout, except in the extreme south-west. The Inn has many villages upon its banks, the highest of which, St Moritz, is 6090 feet above sea-level, while the lowest, Martinsbruck, is 3343 feet. Most of these villages have of late years become, as health and pleasure resorts, clusters of inns, and several English churches are among the conveniences prepared for the great numbers of visitors. The influx of so many strangers has altered many of the old habits of the people; but, though no longer the nearly invariable rule, it is still not uncommon for the young men to betake themselves to the large towns of the Continent, whence they return, with the little fortune gained as confectioners or waiters, to end their days in their cold, lovely valley. Pop. about 11,690, almost all of the Reformed or Calvinistic Church. The language most generally spoken is the Ladin (a corruption of Latin), a Romance tongue, but differing from the other Romance dialects of the Rhetian Alps, and bearing a resemblance to the Italian.

**Engagement**, THE, between Charles and the Presbyterians. See NEWPORT.

**Engelhardt**, JOHANN GEORG VEIT, theologian, was born in 1791 at Neustadt-an-der-Aisch, Bavaria, and in 1822 became professor of Theology at Erlangen. He died 13th September 1853. His writings include a *Handbuch der Kirchengeschichte* (4 vols. 1834), and *Dogmengeschichte* (2 vols. 1839); and he edited, with Winer, a *Kritisches Journal der Theologie* (1824-29).

**Enghien**, a favourite watering-place and summer-resort of the Parisians, lies 7 miles N. of Paris, on a small lake. It has five sulphur-springs, good for the skin and throat. Pop. 2426. —In the Belgian province of Hainaut there is another town of the same name, a busy manufacturing place (beer, salt, lace, linen, and cloth), with 4187 inhabitants.

**Enghien**, LOUIS ANTOINE HENRI DE BOURBON, DUC D', only son of Prince Henri Louis Joseph, Duc de Bourbon, was born at Chantilly, 2d August 1772. In 1789 he quitted France, and travelled through several countries of Europe. In 1792 he entered the corps of *émigrés* assembled by his grandfather, the Prince of Condé, on the Rhine, and commanded the vanguard from 1796 until 1799. At the peace of Lunéville, in the year 1801, he went to reside at Ettenheim, an old château on the German side of the Rhine, not far from Strassburg, and within the territories of the Duke of Baden. When the Bourbon conspiracy, headed by Cadoudal, Pichegru, &c., against the life and authority of Bonaparte, was discovered at Paris, the latter chose to believe that the Duc d'Enghien was privy to it, and unscrupulously resolved to seize the person of the duke. On the night of the 14-15th March 1804 the neutral territory of Baden was violated, and the duke, with two attendants, was captured, and carried prisoner to Strassburg, and thence to Paris and Vincennes. On the early morning of 20th March he was tried before a military commission, consisting of eight officers, and after a five hours' examination was condemned to death. Half-an-hour later, between four and five, he was shot in the castle moat, and buried in the grave already dug for him. So cruel and audaciously criminal an act has fixed a deep stigma on the character of Bonaparte. M. Dupin published the records of the trial, and showed the illegality of the proceedings of the military commission. This illegality was publicly acknowledged by General Hullin, the president of the court. Thiers as far as possible exculpates Bonaparte, while Lanfrey adopts the most adverse verdict, and Welschinger lays much of the guilt on Talleyrand. Fouché said that it was worse than a crime—it was a blunder. After the Restoration, the bones of the judicially murdered duke were re-interred in the chapel of the castle of Vincennes. See *Le Duc d'Enghien*, by Henri Welschinger (Paris, 1888).

**Engine**. See AIR-ENGINE, GAS-ENGINE, STEAM-ENGINE, &c.

**Engineering**, the business of the engineer, is the art of designing and superintending the execution of works of a constructive character, such as roads, railways, bridges, canals, harbours, docks, works for supplying water to towns, drainage and sewerage works, as also the working of metals and the making of machinery.

The duties of the military engineer are defined in the next article. The civil engineering profession is subdivided into several sections. The railway engineer projects and superintends the execution of railways and all the works in connection with them, such as the alteration of roads and streams, the construction of viaducts, bridges, cuttings, and embankments. The hydraulic engineer plans and superintends the works connected with the supply of water to towns, irriga-

tion, drainage, the protection of low lands from inundation, and the use of water as a motive-power. The dock and harbour engineer has the management of all works connected with the sea or navigable waters, such as the construction of piers, breakwaters, docks, harbours, and lighthouses.

The mechanical engineer is principally concerned in the manufacture of machinery, the working of metals, the construction of ships, steamers, cannon, and all the various structures in which the metals bear a prominent part. The marine engineer makes parts of ships, and the machinery in ships and boats; or he takes charge of an engine on board ship. Then there are mining engineers, who discover minerals and manage mines; sanitary engineers, who are specially engaged in the drainage of towns; and electric engineers and many other less prominent divisions of the profession. Any one who tends an engine is also called an engineer. In many engineering works the *contractor* takes a very important part; he executes the works from the designs, and under the direction and superintendence of the civil engineer, and on his ability and good management the success of undertakings very materially depends.

Among the most notable of the engineering works belonging to very remote antiquity are the pyramids of Egypt. The rude stone monuments of the north, as at Stonehenge and Carnac, also testify to some engineering skill. The harbours and temples of ancient Greece are very memorable. The buildings of ancient Rome—its theatres, temples, baths, and aqueducts, its roads, bridges, and drainage-works, vie in extent and magnificence with the most celebrated works of modern times. From that period down to the commencement of the 18th century the most extensive works executed were the canals, embankments, and other hydraulic constructions used by the Dutch for the purposes of inland navigation, and to protect their low lands from the sea; the canals of North Italy; and the cathedrals and fortifications of medieval Europe.

Civil engineering, as a distinct *profession*, may be said to have originated, in England, about the middle of the 18th century; since that time the improvements in the steam-engine by James Watt, its subsequent application to the railway-system by George Stephenson, and its use in navigation have given a great impulse to commerce and civilisation. Among celebrated engineers are the Stephensons, Rennies, the Brunels, Telford, Smeaton, Ericsson, Eads, Krupp, Fairbairn, Armstrong, Siemens, Bessemer, Fowler, and Baker.

The education of engineers should embrace a fair knowledge of pure mathematics, and of the mixed sciences of natural philosophy, such as mechanics, hydrostatics, hydraulics, and optics, as also of drawing and arithmetic. The principal society of engineers in Britain is the Institution of Civil Engineers, established in 1818, 'for facilitating the acquirement of professional knowledge, and for promoting mechanical philosophy.' There are now everywhere colleges and schools in which engineering is a special study.

The more important operations in engineering, and the most famous triumphs of the art, are treated of under such heads as AQUEDUCT, BREAKWATER, BRIDGE, CANAL, DOCK, HARBOUR, LIGHTHOUSE, MECHANICS, MINING, RAILWAYS, RESERVOIR, ROAD, STEAM-ENGINE, STRENGTH OF MATERIALS, WATERWORKS, WEIR, WHEELS. For machinery, see also the articles on Printing, Weaving, Spinning, Metallurgy, and the other arts and trades discussed in this work. And see such works as Cresy, *Encyclopædia of Engineering* (new ed. 1880); Spon's *Dictionary of Engineering* (1874); Smiles's *Lives of the Engineers* (1874); Macquorn Rankine, *Manual of Civil Engineering* (new ed. 1884); Wheeler, *Civil Engineering* (New York, 1877).

**Engineers,** THE CORPS OF ROYAL, formed in 1763, is an important branch of the British army. A similar organisation exists in all regular armies. The duties devolving upon military engineers include the design, construction, and maintenance of fortifications and submarine mining defences at all times, and, during war, the conduct of engineering operations at sieges, mining, bridging, surveying, ballooning, together with the making of roads, railways, and lines of field telegraph. The men, who are called sappers and miners, are therefore selected with a view to these various duties, and with a small percentage of exceptions must have learned some handicraft before enlistment. The service is for seven years with the active army and five in the reserve, or these periods may be three and nine respectively. In addition to ordinary pay they receive 'engineer' pay, varying from £d. to 3d. per hour, or allotted on the piece-work system. There are in round numbers 5000 non-commissioned officers and men in the corps, forming 51 companies; 1 field telegraph battalion, carrying 120 miles of wire and materials; 1 bridging battalion, in 2 troops, each carrying 120 yards of pontoon bridging material; and a field depot quartered at Aldershot.

In India the Bengal sappers and miners consist of 1000 natives, forming 10 companies; those in Madras, 1050, or 10 companies; and those in Bombay, 400, or 5 companies. The officers and higher non-commissioned officers are British.

There are some 900 officers of all ranks in the Royal Engineers, those not doing duty with the men being employed on detached duty in all parts of the empire. Except those of the coast battalion of Submarine Miners and the quartermasters, who are promoted from the ranks, all pass through the Royal Military Academy at Woolwich or Royal Canadian Military College, and on joining the corps undergo a course of special training at the School of Military Engineering at Chatham, which is the headquarters of the corps. They, like the privates, receive 'engineer' pay besides their ordinary pay as officers, commencing with 2s. a day, and are often able, especially in India, to obtain appointments entitling them to large salaries, irrespective of their army rank. Promotion is by length of service, and not, as in other regiments, dependent upon the occurrence of a vacancy in the higher rank.

At the War Office a deputy adjutant-general manages the discipline, &c. of the corps, and the inspector-general of fortifications superintends all works, &c. The Ordnance Survey is carried out by the Royal Engineers, the office being at Southampton. The militia and volunteer engineers are affiliated to the corps of Royal Engineers. The militia engineers in 1888 consisted of 2 regiments of fortress engineers and 5 divisions of submarine miners; the volunteer engineers of 22 regiments of fortress and railway engineers, 1 of railway transport, and 9 divisions of submarine miners. See Major-general Whitworth Porter's *History of the Corps of Royal Engineers* (2 vols. 1889).

**Engineers,** in the Royal Navy, are the class of officers who attend and manage the machinery on board vessels of war. On the first introduction of steam into the service engineers were obtained from private engineering establishments, or from merchant-steamers, and their exact status was undefined and ambiguous. In 1847 and 1848 their position became more recognised, and the higher grades were raised from the rank of *warrant officers* to that of *commissioned officers* of a civil branch. This introduced a higher class of men into the navy. At the present day the use of steam for every purpose has so enormously increased in war-

ships that the engineers' position has become one of the first importance, and high emoluments, with enhanced rank, have induced some of the ablest men to serve afloat. There are now the grades of chief-inspector of machinery, inspector of machinery, steel-engineer, staff-engineer, chief-engineer, engineer, and assistant-engineer, ranking with colonel, lieutenant-colonel, major, captain, and lieutenant in the army respectively, and with salaries varying from £638, 15s. to £109, 10s. Some ten officers are borne on the Navy List for temporary service. All these are commissioned officers, and are strictly examined before admission; their rank and promotion being by selection, and dependent on skill, character, and length of service. A chief-engineer is expected to be able to make notes in the log of every particular concerning the engines and boilers; to draw rough sketches of the machinery, with figured dimensions fit to work from; to understand and manage everything relating to engines, boilers, and furnaces; to understand practical mechanism generally, and the principles of theoretical mechanism. The engineer and assistant-engineer are expected to possess, in a smaller degree, the same kinds of knowledge and skill. By an Order in Council of June 29, 1888, the rank of engineer student was established, vacancies to which are principally filled by open competition. Candidates must not be less than fourteen, nor more than sixteen years of age on the 1st day of May in the year in which they are examined. Applications for forms to be filled up by persons who wish to compete must be sent to the Secretary, Civil Service Commission, London, S.W., on or after the 1st of January in each year, and care must be taken that such filled-up forms are returned before the 15th March following. The Educational Examination is held annually, in April, at London, Liverpool, Portsmouth, Devonport, Bristol, Leeds, Newcastle-on-Tyne, Edinburgh, Glasgow, Aberdeen, Dublin, Belfast, and Cork, the subjects being arithmetic, handwriting, accuracy and intelligence in writing from dictation, composition, grammar, French, German or Italian, geography, algebra, including quadratic equations, Euclid, and mechanical drawing. A fee of one shilling is required from every candidate, and successful candidates will be entered as engineer students at H.M.'s dockyard at Devonport. The parent or guardian of each engineer student is required to make six annual payments during the six years of the student's training—viz. £30 each year for the first two years, £20 for the third year, £15 for the fourth year, and £5 each year for the fifth and sixth years; also to provide uniform, clothing, &c. Board and lodging and medical attendance will be provided by the Admiralty. The weekly pay of students ranges from one to ten shillings, and they are examined as to proficiency once a year.

The Navy Estimates for 1888-89 provided for 631 engineer officers of all grades, at a cost of £144,000. The changes in this branch of the service are more frequent than in any other, and are all for the better, proving the estimation in which the engineers are held and the importance of the position they occupy.

**England** is the southern, the larger, and by far the more populous portion of Great Britain, the largest and most important of European islands. Separated from Belgium, Holland, Germany, and Denmark by the North Sea, from France by another 'streak of silver sea,' the Channel, and from Ireland by St George's Channel and the Irish Sea, the kingdom of England and Wales has only one short land frontier, that towards Scotland. In shape it forms an irregular triangle, of which the eastern side measures in a straight line 350 miles, the

southern 325 miles, the western 425; but its shores are so deeply indented by bays and estuaries as to make the coast-line longer in proportion to the size of the land than in any other country but Scotland and Greece.

England has for hundreds of years been one of the leading powers of Europe, one of the great moving forces of the world, and, through her colonies, a veritable mother of nations; but her area is relatively very small. The area of the British Islands (121,700 sq. m.) is but  $\frac{1}{175,000}$ th of the surface of the world. The colonies and dependencies of the empire of which England is the centre cover a seventh of the land-area of the globe. England without Wales (51,000 sq. m.) is about the size of Roumania, less than a fourth of France or of Germany, and is but little larger than the single state of New York (49,170 sq. m.); and England with Wales (53,000) is not equal in area to the state of Georgia (59,473), and is not a fourth of the size of Texas. Twenty-nine of the states in the Union are each larger than England, several much larger than the whole United Kingdom.

Her name 'this noble realm of England' owes to the *Engle* or *Angles*, who with the kindred *Jutes* (*Geatas*) and *Saxons* (*Seaxe*) descended on the greater part of what used to be known as Albion or Britain (see *BRITANNIA*), conquered and occupied it in the 5th and following centuries (see *ANGLES*, *ANGLO-SAXONS*). These kindred peoples all learned to call themselves *Englisc* or English, and by *Englaland* they understood the whole area now occupied by them—an area which in the 7th century extended over more than the half of the island from the Forth to the English Channel. South-eastern Scotland, as occupied by Angles, and not by Saxons or Jutes, was in the stricter sense English; and the people of the non-Celtic parts of Scotland, though now markedly differing from the southern English, are in blood and in mental and physical type at least as English in the wider sense as the people of Oxford or Kent. Political circumstances led the English and Anglicised Celts of North Britain beyond Solway and Tweed to become the subjects of the alien Scottish king, but their language they still called *Inglis*, as distinguished from the Erse of their Scottish or Gaelic fellow-countrymen.

The people of the southern kingdom constitute nearly three-fourths of the inhabitants of the three kingdoms; the English language in some form is that of all but a small minority in any of the three; the English literature is the common inheritance of the whole; the constitution and polity of England, slightly modified, is the British constitution under which the three kingdoms have unitedly become glorious, and has been the original model for the free constitutions of all free peoples the whole world over. Hence it is not strange that not merely by Englishmen, but by all foreigners, the name of England is used for what, after the union of Scotland and England in 1603, became officially Great Britain, and even for the whole empire, which, since the Irish Union of 1801, is strictly the United Kingdom of Great Britain and Ireland.

The physical features, as also the geology, of the British Islands are obviously so closely connected that it is convenient to treat of them collectively under the head of *GREAT BRITAIN AND IRELAND*. There also the general facts and figures fall to be given which concern the three kingdoms jointly—exports, imports, trade, shipping, &c., except in so far as they are separately discussed under such heads as *AGRICULTURE*, *ARMY*, *COLONIES*, *COUNTY*, *EDUCATION*, *EMIGRATION*, *NAVY*, *PARLIAMENT*, *RAILWAYS*, &c. Here, on the other hand, some of the facts distinctive of England, which admit of being succinctly stated, may well be noted.

The area of England without Wales is 50,823 sq. m.; that of Wales, 7363; together, 58,186. So that, as the area of the United Kingdom, with Scotland, Ireland, Man and the Channel Islands, is 120,382, England alone covers 42 per cent. of the whole. Wales 6, and England and Wales 48 per cent. The population of England and Wales in 1650 is estimated to have been 5,450,000, the increase up to that date having been slow. In 1750 it was probably 6,400,000. From that date the increase was rapid; and the census of 1801 showed a population of 8,892,536. In 1841 the population of England alone was 15,002,443; in 1851 it was 16,921,888; in 1861, 18,954,444; in 1871, 21,495,331. That of Wales was at the corresponding dates 911,705; 1,005,721; 1,111,780; 1,217,135. At the census of 1881, England had 24,613,926, and Wales 1,360,513, or together 25,974,439. So that in that year the population of England alone was 69.8 per cent. of the total population of the United Kingdom (35,241,482); of Wales, 3.8; and of the two, 73.6. In 1888 the total population was estimated at 37,453,574, and the percentage of England and Wales may be set down in round numbers as making up more than 76 per cent., or three-fourths of the total population of the United Kingdom. The density of the population in England is greater than in any other European country except Belgium. In 1881 it was for England alone 484 per sq. m.; for England and Wales, 446; whereas for Scotland it was only 125. In England and Wales there were, in 1881, 19 towns with more than 100,000 inhabitants (in 1888, 22 such towns), in Scotland only 6, in Ireland 3. In England there were 45 above 50,000, in Scotland 6, in Ireland 3.

At the census of 1891 the population of England was 27,482,104, and of Wales 1,518,914. For 1881 the figures of the counties were:

Counties.	Area in statute acres.	Population.
Bedford.....	204,088	140,473
Berks.....	462,210	218,308
Buckingham.....	477,151	176,323
Cambridge.....	524,035	185,501
Chester.....	057,123	014,087
Cornwall.....	803,005	330,080
Cumberland.....	070,161	250,017
Derby.....	053,024	401,014
Devon.....	1,655,208	003,505
Dorset.....	027,205	101,023
Durham.....	047,502	807,258
Essex.....	097,032	576,434
Gloucester.....	789,000	573,433
Hampshire.....	1,037,764	603,470
Hereford.....	532,018	121,002
Hertford.....	405,141	403,000
Huntingdon.....	225,515	50,491
Kent.....	008,302	077,700
Lancashire.....	1,208,154	3,451,441
Leicester.....	511,007	321,253
Lincoln.....	1,707,870	400,910
Middlesex.....	181,317	2,020,485

York.....	3,882,861	2,880,604
Total of England.....	32,527,070	24,013,023
Total of the twelve Welsh Counties.....	4,712,281	1,300,518
Total of England and Wales.....	37,239,351	25,974,480

For the Welsh counties, see WALES. The areas of the English counties are given in square miles in the articles on the counties.

The climate of Britain is insular and comparatively equable, milder on the whole than that of any region on the same northern parallel (see CLIMATE), with smaller extremes of heat and cold, with colder summers and warmer winters. England is milder than Scotland, and though moist compared with continental countries, less moist than Ireland. In spite of its dull skies and frequent rains, it was wisely said by Charles II. that the English climate 'invited men abroad more days in the year and more hours in the day than any other country.'

The situation of Britain has been shown to be in the very centre of the land-masses of the globe, a very great advantage for commerce and navigation; England, being nearer the European shores, enjoys the advantage in higher measure than its sister-kingdoms. Its seas are less stormy, and it has a greatly more developed system of navigable rivers.

The north-west of England is mountainous and hilly, the east and south mainly a plain crossed by lines of low hills. The fertility of England is much greater than that of Scotland or Ireland, especially that of the wheat-bearing area of eastern England. The agriculturally productive area of England is estimated at 80 per cent. of its total, and of Wales 60 per cent., whereas that of Scotland is only 28.8 per cent., and of Ireland 74. England, whose surface has been said for variety to be an epitome of Europe, is very rich in minerals, of which coal and iron are incomparably the most important, making nine-tenths in value of the whole. The output of coal and iron in England is vastly greater than in Scotland, and Ireland is exceptionally poor in both.

Of the population of England it is impossible to say what proportions belong to the various racial elements that have gone to form it. A non-Aryan race, perhaps Enskarian, must have preceded the Celts, who conquered and assimilated them: the Celts (q.v.) are still the predominant race in Wales. The Roman armies introduced into the towns a considerable element, comprising doubtless Gauls, Germans, Iberians, Italians, Dacians, Phrygians, and the other various races who went to constitute the legions of the empire. Danes and Norman-French were the latest people who came in large numbers. But the great problem is: Did the Teutonic Angles, Saxons, and Jutes exterminate their predecessors the Celtic Britons, or did they over great part of the country mainly assimilate them? (See the history below.)

What is certain is that out of these various stocks a well-marked race has been formed, strenuous, self-reliant, resolute in defence of its rights, daring, laborious, industrious, and ambitious. Its essential character, with marked modifications, it has transmitted to the great daughter-nation of the United States, and to the colonies of Britain. And this race it is which has given its language and in part its institutions to over 100 millions of the world's inhabitants, and with the help of its Scottish and Irish kinsfolk, has created for its and their offspring a glorious heritage in the English literature. England became the classic land of liberty, where the power of the state, based on ancient precedent, has been developed so as least to infringe on the freedom of the individual—a development sketched in the succeeding history, and continued on similar lines in the United States.

England became also the special home and headquarters of agricultural enterprise, mineral production, machine-making of all kinds and steam-power, of commerce, navigation, and shipping.

England did not start in the race of commerce as early as many of those who are still her rivals. Long after France, Flanders, and parts of Germany were great manufacturing centres, England was an agricultural and pastoral country, wool its chief production and staple export. The woollen goods for its own use were mostly manufactured abroad. Edward I. did much to encourage such trade as there was in opening English ports to foreign merchants, and Edward III. induced many weavers, dyers, and fullers from Flanders to settle in England. In the 14th century woollen cloth was manufactured at Bristol, London, and Norwich, and began to be exported. Linen and silk weaving became of some importance. Coal was exported from Newcastle to France in 1325; but it was later ere English entlery was known abroad. Great progress took place in Elizabeth's reign; under James I. Scotland began to have a share in the commerce of the world; and the reign of William III. marked a new era, for the immigration of French refugees after the revocation of the Edict of Nantes in 1685 soon told on the quality and amount of English manufactures. But the great and rapid advance which made the commerce and manufactures of England the wonder of the world dates from the latter half of the 18th century, and is largely owing to the unparalleled development of machinery, the use of steam as a motive power, improved communication, and later, steam-navigation and railways.

It is very observable that the local distribution of the great industries of England has changed very greatly since the 17th century. At the Revolution period, most of the greater towns of England were in the south and east; but these have now been long outstripped by northern rivals, and what were then important manufacturing towns have in many cases sunk into mere villages. After London, the chief towns were Bristol and Norwich, each with some 29,000 inhabitants. Exeter with 10,000 was probably equalled by York. Worcester and Nottingham may be set down at 8000; while Leeds had but 7000, Manchester hardly 6000, Birmingham, Sheffield, and Liverpool perhaps less than 4000. Now English manufacturing industries have most of their special seats in the north. If we draw a line from the mouth of the Severn to the Wash, we find that to the south-east there are hardly ten towns, not seaports or suburbs of London, which have a population exceeding 25,000; to the north-west of the line there are above fifty inland towns of that size. It is very significant that all the coal of England is found north of the line named, about or near the populous money-making towns.

The general figures that measure the vast commerce of the United Kingdom will be given for comparison with those of other countries at GREAT BRITAIN AND IRELAND. In many cases it is not possible to separate the shares proper to England, Scotland, and Ireland; but the greater wealth of England may be shown by a few miscellaneous figures as to textile industry, the collecting of customs, and the assessments for income-tax.

There were in the United Kingdom at the time of the Report of the Inspectors of Factories in 1885 in all 2635 cotton-factories; of these England and Wales had 2481, Scotland 147, Ireland 7. Of woollen-factories there were in all 1918; of these 1503 were in England and Wales, 274 in Scotland, 141 in Ireland. In worsted-factories the disproportion was still greater. There were 7465 textile factories in all, of which 6359 were in England, 776 in Scotland, and 330 in Ireland. The customs collected at London in 1888 were £9,976,405; at Liverpool, £2,582,170; at other English ports, £2,046,026; whereas the total collected in Scotland in that year was £1,426,284, and in Ireland £1,824,079. Though this indicates with approximate accuracy the move-

ment of shipping, it is true that a share of the vessels in English ports belongs to Scottish owners, and Scotland builds in some years almost as large a tonnage as England does. The total amount of the annual value of property and profits assessed to income-tax in 1887 in the United Kingdom was £629,397,962; the share of England being £533,040,455; of Scotland, £57,910,114; and of Ireland, £36,447,393. Other figures of a similar kind will be seen under SAVINGS-BANKS.

In no way can a better conception be formed of the state of England at different periods than from the works of topographers, foreign visitors, &c., such as Leland and Camden for the 16th century; Drayton and Fuller for the 17th; Defoe, Pennant, Pecoche, Moritz, and Young for the 18th; Cobbett, Emerson, Hawthorne, Esquiros, Taine, Kohl, and Burroughs for the 19th. See also Escott, *England: her People, Policy, and Pursuits* (1879; 2d ed. 1886); R. Grant White, *England Without and Within* (1881); Thorold Rogers, *History of Agriculture and Prices in England* (6 vols. 1866-68); T. H. Ward, *The Reign of Queen Victoria: a Survey of Fifty Years of Progress* (2 vols. 1887); A. Innes Shand, *Half a Century of Changes* (1887); W. Besant, *Fifty Years Ago* (1888); besides the government bluebooks and other statistical annuals.

#### HISTORY OF ENGLAND.

Though the history of England cannot properly be said to begin till the 5th century, when the Teutonic tribes who have given the country its name established themselves in the island, it is of some importance to understand the condition of the people whom they supplanted. There can be little doubt that, speaking generally, the inhabitants of the island when conquered by the Romans were of Celtic origin. They were not indeed entirely homogeneous; two distinct branches of the Celtic language were spoken, the Gauls of France are mentioned by Cæsar as having exercised authority over the island, the Belgæ had certainly established themselves there, and certain tribe-names lead to the belief that men of Teutonic origin had already formed settlements. The island lying at the extremity of Europe had probably formed a natural refuge for tribes driven from their own lands, and a natural prey of those in search of new homes. But on the whole there can be little question that the population was Celtic. It had passed beyond the age of barbarism, and when Claudius determined to complete the conquest which Cæsar's temporary raid in 53 B.C. had foreshadowed, some sort of general confederacy was in existence, a king of the name of Cunobelin reigned at Camlodunum, near Colchester, and the existence of not less than forty varieties of his coins bear witness to the greatness of his influence and the comparative civilisation of his rule. His son, Caractacus, and, eleven years later, Boadicea, queen of the Iceni, opposed a long and terrible resistance to the Roman arms; but the arrival of Agricola in 78, and his eight years of wise government, brought the country at length into the condition of a Roman province. The conquest of the whole island was, however, never completed. It seemed good to the Romans to limit their successes, and to attempt by great defensive works to exclude from their dominions the still unconquered Celts of the north. Lines were erected between the Firths of Forth and Clyde, and between Bowness and the mouth of the Tyne. The intermediate district was a scene of constant warfare, both lines were from time to time strengthened, and the more southern of the two changed during the 4th century into the great Roman Wall (see SEVERUS, WALL OF). Within this limit the occupation of the country was complete. For two centuries it was probably merely a military occupation, and at no time does it appear that

there were more than 20,000 Roman soldiers in the province; but as time passed on it appears certain that the influence of the conquerors became largely felt. Towns, the remains of which still exist, were built, bringing with them of necessity the close intercourse of trade, and numerous traces of villas in many parts of the country show the spread of peaceful Roman life. It was the policy of Rome in its provinces to debar the middle classes from the use of arms, and though possibly, as in India at present, the native nobles and princes were allowed to keep in some degree their rank, it was under the shelter of the Roman legions that civilisation advanced, and upon their prowess that safety from the threatened encroachments of unconquered Celts or marauding Teutons was secured. It is impossible to say how far civilisation had extended, or how far the language had been influenced by the Roman occupation. The close resemblance of many common agricultural terms, of the names of plants, and so on, to Latin words would lead to the belief that the language was Latinised. On the other hand, local names, the names of woods, mountains, and rivers, are largely Celtic. It seems not improbable that both high civilisation and Roman speech were chiefly concentrated along the great roads, and round the cities and stations with which these were lined.

The disturbances of the empire, and the danger which threatened it from the pressure of the outlying barbarians, compelled in 411 the withdrawal of the legions; and the half-Romanised inhabitants who had learned to rest on the support and valour of their conquerors were left to their own resources to withstand the unconquered Celts of the north, now known as Picts, and their piratical allies the Irish Scots. The movement of the barbarians had affected the people on the borders of the North Sea; the Jutes from Jutland, the Angles from Sleswick, the Saxons from Holstein and the neighbouring coasts were covering the sea with their expeditions. Summoned to the assistance of the civilised Britons, a party of Jutes found means to establish themselves in Kent. It was an example readily followed. Before the year 600 Saxons and Angles had formed settlements extending as far northward as the Forth. About that year the various princedoms may be regarded as merged in two considerable and rival powers, Northumbria and Kent; while a third, Wessex, fated ultimately to devour the other two, lay along the south, at present interested in extending its power westward. It still remains a question whether the invaders destroyed the conquered inhabitants or not. On the strength of certain expressions in the chronicle Gildas it has been held that no quarter was shown; but it is more probable that, as in other cases of conquest, the invaders settled down in the midst of the conquered population, content to rule as manorial lords over their own free followers and the slaves and dependents of their predecessors.

It was long before the various settlements of the Saxons were fused into one. Long before political union was reached, the unity of the people found expression in a single Christian church. While the powers of Northumbria and Kent were still balanced, the marriage of the king of Kent with a Frankish princess offered an opportunity for the evangelisation of the country. Augustine and his fellow-missionaries landed in Thanet in 596, and, well received by the king, found a home in Canterbury. A similar circumstance brought Christianity to the north; a Kentish princess married to Edwin of Northumbria took with her Paulinus, and established Christianity in York. The change of religion went near to destroying the Northumbrian power. Heathenism found a champion, and Penda, uniting the central tribes into the kingdom of

Mercia, for a while established his supremacy over Northumbria, and drove the Roman priesthood to flight. The gap thus left was supplied by the devoted missionaries of the Celtic Church settled in Lindisfarne. But the restoration of the Northumbrian power was fatal alike to heathenism and to the Celtic Church. After the Council of Whitby in 664, the Roman Church regained predominance, and was organised in a single archiepiscopal see by Theodore of Tarsus, holding his appointment from Rome. After the fall of Penda, the supremacy of the northern kingdom was unquestioned, till some sixty years later it gave way to Mercia. About the year 800, however, both Mercia and Northumbria had to yield to the third power. Egbert, king of Wessex, who had seen something of centralisation in the court of Charlemagne, during the thirty-six years of his reign gradually brought under his power all the English kingdoms, whether Anglian or Saxon, and continuing the hereditary struggle of his people with the British populations, established a permanent superiority over all England, with the exception of the Britons north of the Dee.

But already an enemy had made its appearance to which the newly centralised kingdom was to yield. The Danes, issuing from the Scandinavian coasts, had before the death of Egbert begun to harry the country. At first as robbers, then as settlers, and finally as conquerors, for two centuries they occupy English history. During the reign of Ethelred their incessant but isolated incursions assumed the form of an invasion, East Anglia passed into their hands, and their leader, Guthrum, took to himself the title of king. For seven years Alfred on the throne of Wessex carried on a deadly struggle with this rival power, and at length concluded a treaty of partition at the Peace of Wedmore (878), surrendering to the Danes the north and east of England to be held by them as vassals of the Saxon king. The supremacy of Wessex was thus secured, and ripened in the following reigns into something little short of an imperial authority. Edward the Elder was not only recognised as the overlord of Mercia and Northumbria, but the Welsh kings swore alliance, and the kings of Scotland and Strathclyde acknowledged him as their father and lord; he treated on equal terms and contracted marriage alliances with the greatest princes of Europe. His position was fully vindicated by his son Athelstan, under whom, perhaps, the West Saxon monarchy reached its highest point of greatness. The decisive battle of Brunanburh, in 937, won over a complicated confederation, dealt a death-blow to all opponents. The reign of Edgar the Peaceful, and the government of his great minister Dunstan, closed the period of Saxon greatness. From this time onwards weak kings, factious nobles, and a broken organisation were unable to resist the renewed incursions of the Scandinavian tribes. The jealousies between the various sections of the people, restrained by the strong central authority of the late kings, broke out afresh. The northern kingdoms where Danish law prevailed afforded a natural support for the invaders. The alliance of King Ethelred with the Normans, and his marriage with Emma, a Norman princess, only added a fresh element of weakness by the presence of her foreign followers. Recourse was had in vain to large payments to the Danes, and to the cruel and treacherous murder, on St Brice's Day, 1002, of the Danes settled in Wessex. Ten years later all opposition had been overcome, and Sweyn, the leader of the invaders, was practically king of England. He was succeeded by his son Canute, and though a brief outburst of vigour under Edmund Ironside enabled the English to secure a division of the country, the death of their leader compelled them

to submit to Canute. Under its Danish king England was ably ruled, and was in some respects the head of a Scandinavian empire. But Canute's two sons failed to continue their father's work. Opportunity was allowed for the rise of Godwine, Earl of Wessex, and on the death of Hardicanute in 1042, Edward the Confessor, the son of Ethelred, resting on the support of the great earl, re-established the house of Cerdic on the throne. Educated in Normandy, he surrounded himself with foreign friends, and filled the high places of the kingdom with Frenchmen. As leader and representative of the national feeling, Godwine succeeded after a while in driving the foreigners from the country, and establishing himself in a predominant position over the south of England. In the north the influence of the earls of Mercia prevented his absolute supremacy. He handed on both his power and his rivalry with the northern earls to his son Harold. Successful against his rivals, Harold placed most of the earldoms in the hands of his brothers. So completely was he recognised as the first of Englishmen, that upon the death of the king the Witan had no hesitation in electing him to the throne.

In thus choosing a king from beyond the limits of the royal family the Witan had transgressed a well-established English custom. A formidable rival claimant at once appeared. William, Duke of Normandy, a cousin of the late king, demanded the throne as next of kin, and pleaded the promise of the Confessor. A second enemy threatened Harold: his brother Tostig had proved a traitor and had been banished; he now returned in company with the Norwegian fleet. The northern earls opposed him, and Harold, hastening to their assistance, won the battle of Stamford Bridge over the invaders. But the decentralised character of the English constitution and the strength of family rivalry made lengthened union impossible. When, three days after, on the 28th of September 1066, the Norman duke landed at Pevensey, it was single-handed and with hastily collected forces that Harold met him. The great battle of Senlac, near Hastings, was decisive, Harold and his brothers were slain, and England was left without a king. Again the jealousy between Wessex and Mercia prevented either a combined national opposition or the election to the throne of a native prince. William had little difficulty in slipping into the vacant post and securing his election by the Witan. The series of local efforts at opposition which followed his election proved unsuccessful, and by 1070 his authority was recognised throughout the country.

The change of dynasty thus effected connected England with the great movements of the Continent. Up to this time it had been somewhat isolated. Though its church was in communion with Rome, and had frequent intercourse with it, it was distinctly a national church; though feudalism was rapidly advancing, it had pursued an independent and national course of development. It was in some degree as the champion of the great system of Western Christianity that William had put forward his claims, and he brought with him followers imbued with all the principles and forms of continental feudalism. All the varieties of class and of land tenure which had arisen spontaneously in England were now assimilated to those existing where complete feudalism was in force; the connection with Rome was ratified by an entire change in the episcopacy. But William had no idea of assuming the position of a chief among equals, or of subordinating his authority to that of the church. He found in the organisation of the conquered kingdom principles which enabled him, while using feudal language, to be in fact an

absolute king, and to set such limits to the power of Rome as to keep the church virtually in subordination. The Norman kings, when not engrossed in foreign enterprises, were occupied in establishing, in opposition to the nobility and the church, that powerful monarchy which the Conqueror had established. They found in the old institution of the national militia an instrument with which to oppose the feudal levies of the barons. An administrative system centred in the crown, and working chiefly through the machinery of the exchequer, went far to centralise the government. Triumphant suppression of insurrections enabled them to get rid of the feudal baronage of the Conquest, while a new nobility of administrative origin and attached to the national system gradually took its place. But the death of Henry I. leaving only a daughter, Matilda, gave room for a disputed succession. All the discordant elements which the royal power had held in repression burst into life. The reign of Stephen was a time of constant civil war, during which the nation learned from the intolerable tyranny under which it groaned the value of the repressing hand of royalty. The miserable time was brought to a close chiefly by the mediation of the church. Matilda's son Henry, already a powerful prince in France, was accepted as the heir to the throne, and practically intrusted with the restoration of order. It was with the general concurrence of the nation that he was able to re-establish upon a broader and better basis the powerful monarchy of his predecessors. A series of great administrative reforms brought justice and finance into the hands of the king and his intimate council or *Curia Regis*, and went far to break through the quasi-independence of the land-owners. The suppression of a great insurrection affecting all his possessions, and supported by the kings of France and Scotland, left him unquestioned master of his kingdom so far as the baronage was concerned. His attempts to reduce the church to subordination were less successful; the opposition of Becket to the enactments of the Council of Clarendon produced a disastrous struggle with Rome. But though technically worsted, Henry's power suffered no serious diminution from his defeat. He handed on to his son a powerful and well-organised monarchy, in which the feeling of national unity had made great advances. His system proved strong enough to support the continued absence of Richard in the Crusades and in his French dominions; national life even acquired increased strength by the self-government which was thus forced on the administration.

In the hands of Richard's successor the evil effects of the enormous power concentrated in the crown became obvious. Boastful, tyrannical, and weak, John excited the anger of all classes. The disgrace he brought upon England, the shock thus given to the rising feeling of national pride, afforded an opportunity for the exhibition of the discontent he had roused. He allowed himself to be stripped of all his French possessions; he plunged into a struggle with the Papal See, was excommunicated and deposed, and formally surrendered his crown into the hands of the pope. The nobility, freed from connection with the Continent and supported by all parties smarting alike from the evils of misgovernment and the shame of disaster, appeared as the true leaders of the nation, and wrung from the humbled king that great charter which secured, in the form of a solemn treaty, the foundations of the future liberties of England. To make the charter a reality, and to secure the orderly development of these liberties, was the work of the great king Edward I. John's compact with the people proved

insufficient to restrain the personal and capricious exercise of the royal power in the hands of his son, Henry III. The surrender of the crown proved more of a reality than was expected; the Papal See, unable to establish a temporal suzerainty, mercilessly fleeced the people and the church, and the country was filled as of old with foreigners, on whom wealth and high places were lavished. The finances fell into utter decay. At length a demand for money to support, in the interest of Rome, the claims of the king's son to the throne of Sicily brought matters to a crisis, and in 1258 the barons passed the Provisions of Oxford, drove Henry's foreign friends from the kingdom, and virtually superseded the crown by a committee of government. Henry's attempts to break from the restrictions laid on him produced an armed insurrection, and Simon de Montfort, at the head of the barons and the commonalty of the towns, defeating the royal forces at Lewes, established a revolutionary government of which he was practically the master. But the jealousy with which the nobility regarded the rise of Montfort allowed Edward the Prince of Wales to come forward as the leader of a party at once conservative and reforming. His accession to the throne gave him an opportunity of carrying out his views. In the parliament of 1295, a complete assembly of all estates, he gathered into a national centre all the scattered elements of representation and self-government which had long existed in the county courts. The principle that where all were concerned all should have a voice was acknowledged, and the national liberties were placed in the charge of an assembly in which all orders were included. At the same time the position of the crown was maintained and rendered effective by the large powers still left in the hands of the king's council. For many years the struggle between parliament and prerogative remained undecided; but armed with the power of taxation, and taking advantage of the wants or weaknesses of the sovereign, the parliament continued to make good its position as the national council. At the close of Edward III.'s reign it was able to attack and impeach the ministry. The success of Richard II. in ridding himself of the influence of his uncles by which his youth had been surrounded, and his vehement assertion of the powers of the crown, produced a revolution which closed the struggle, and Henry IV. came to the throne with a parliamentary title, while the council nominated in parliament became in fact a body of national ministers.

The rise of parliament had gone hand in hand with the assertion of national life. Edward I. had not only marked out the lines the constitution was to follow, he had rid England of foreign influences. Busying himself but little with the Continent, he had devoted his attention to the conquest of Wales and Scotland. His death before the completion of his conquest of the northern kingdom allowed the Scots to inflict a final defeat upon his weaker son at Bannockburn. But the national feeling of the English, in abeyance during the political disturbances of Edward II.'s reign, reasserted itself in the ambitious efforts of Edward III. to place himself upon the throne of France, and was strengthened by the brilliant victories which attended them. Though the victories were useless, and the war a series of raids rather than a well-considered conquest, the effects at home were of great importance. The continual want of money forced the crown to frequent concessions to the parliament; the spirit of the people was raised by success; and the life of the soldier played an important part in liberating the lower orders from serfdom. The viliage of earlier times had been gradually declining, and rent and

wages were taking the place of villen tenure and forced service. The terrible ravages of the Black Death upset for a while the economic arrangements of the country, and the attempt to drive back the liberated serf to his old position caused the great rising of Wat Tyler in 1381. The insurrection was suppressed, but a death-blow was practically dealt to serfdom. In close connection with this upheaval of the working-classes was the movement in opposition to the church. The doctrines of Wyclif and the Lollards, so much in harmony with the democratic movement, could not fail largely to influence it, and for a while hostility to the church played a considerable part in parliamentary history.

The completion of the constitutional system marked by the accession of Henry IV. did not prevent the recurrence of disorder, but during the reign of his son full harmony existed between the king and people. The disturbances which had broken out in France afforded an opportunity for renewing the war, and Henry V. found no difficulty in carrying the people with him in his victorious attacks upon that country. A statesman as well as a conqueror, his progress was very different from that of Edward III. The Treaty of Troyes seemed to promise the ultimate union of the two kingdoms, but the work of consolidation was scarcely begun when the great king died, intimating to those who should carry on the work that the occupation of Normandy should be the limit of their aims. The foreign success and domestic harmony was of short duration. Though the power of the nobles as feudalists had disappeared, they were still too strong to accept easily the co-operation of the other orders in a national system except from the hands of a powerful ruler. Their strength had been increased by the great position given to the royal princes. The parliamentary establishment of the younger branch upon the throne had opened the door to the rival claims of hereditary succession. A strong government was scarcely possible during the infancy of Henry VI., especially as the council of regency found in the Duke of Gloucester, a man of ill-regulated ambition, an opponent with whom it was difficult to deal. His greater brother, the Duke of Bedford, devoted himself chiefly to the affairs of France, and though he had succeeded in maintaining some degree of order in England, his early death was the signal for an outbreak with which the council and subsequently the young king proved unable to cope. Continual disaster in France still further discredited the government. Taking advantage of the claim of hereditary right, the Duke of York came forward as the champion of order. The nobility ranged themselves on one side or the other of the contending parties, and the country became the seat of a cruel dynastic war. The Yorkists were victorious in the struggle. The death of their old and moderate leader placed at their head his son Edward, a man of great ability imbued with the morality and principles of an Italian despot, and as the long regency had inevitably replaced in the hands of the council much of its independent power, Edward IV. found little difficulty in employing it for his own purposes. Parliament ceased to have much importance except to register the sovereign's will or to grant submissively the taxes he required. In the earlier struggles for national liberty the king had found his chief opponent in the baronage, and subsequently as leaders of the nation the nobles had exercised a great restraining influence. But in the internecine struggle of the Wars of the Roses they had committed political suicide, and Edward IV., surrounded by a nobility of his own creation, and armed with the powers of prerogative, which had never been formally abrogated, found himself able to establish a practical absolutism. The family dispute had not, however,

reached its last act; Edward's successor, Richard III., rendered himself odious to all classes of the people, and the battle of Bosworth placed upon the throne a prince who claimed to be a representative of the Lancastrian House, and whose position was so far less absolute than his predecessors that he acknowledged that he was king by the will of the people.

The accession of Henry VII. and the Tudor House opens the second act of the drama of English history. The great principles of the middle ages had passed away; it was the age of the rebirth of learning; printing had been invented; firearms were superseding the lance and bow; the discovery of the western world was soon to excite the spirit of nautical enterprise; capital was taking the place of the restricted guild system; the inclosure of commons was changing the face of the country, depopulating the fields and filling the cities; the church had begun to be shaken from its foundations. In the midst of this changed society the new dynasty had ascended the throne, claiming to rest upon the popular will, but invested with all the absolute authority with which the late reigns had surrounded the crown. It is not perhaps going too far to say that the king was endowed with a temporary dictatorship. The typical representative of this phase of government is Henry VIII., a man in whom gross passion and unscrupulous determination to gratify his own will were curiously blended with a certain amount of culture and a real desire for the well-being of his people. Charged as it were with the duty of re-establishing an orderly national life upon a strong monarchical basis, he plunged into war as a ready means of asserting national power. France and Spain were already on the threshold of their great struggle for the supremacy of Europe, and it was in strict accordance with the tradition of English policy that Henry allied himself with the Spanish house. But a change was speedily to pass over the foreign relations of England. Instigated by his passion for Anne Boleyn, Henry demanded a divorce from his Spanish wife; the opposition of the papacy precipitated the Reformation in England, and transferred the national hostility from France to Spain. The difficulties he encountered in his pursuit of the divorce brought him face to face with the one weak point in his position as absolute monarch. The possibility of the assertion of paramount authority by a foreign prince had been studiously hidden from him by his ecclesiastical minister Cardinal Wolsey, who, himself master of the church, had thought to avoid all contest of authorities by devoting his power to the service of the crown. Such a possibility was now suddenly revealed to him. The fall of Wolsey and the substitution in his place of Thomas Cromwell supplied the king with a very able instrument for a high-handed assertion of the independence of the English Church. The movement found support in the excited animosity to the doctrines and practice of Rome which was filling Europe. Led by the energy of Cromwell, Henry proceeded beyond mere separation to the destruction of much of the apparatus of the old church. Reformed liturgies, an English Bible, the dissolution of the monasteries, seemed to secure a triumph for the advanced reformers. But the minister had overshot the desire of his master, and the reign closed amid Henry's efforts by even-handed severity to establish the supremacy of the crown without allowing the predominance of either party. So delicate an equilibrium could not be maintained. A burst of reforming zeal, supported by ministers of questionable character and still more questionable prudence, went far to destroy the position of England; and it was not without a very general consensus in her favour that Mary, the champion of the old faith, ascended

the throne. Unfortunately, her birth and natural prejudices led her to ally herself closely with Spain. A great reaction in favour of Roman Catholicism throughout Europe had begun; Spain was at the head of the movement, and there seemed every probability that England would lose its national independence and be bound not only to the ecclesiastical supremacy of Rome, but to the temporal supremacy of Spain. Religious persecutions of a severity unknown in England added strength to the angry feelings then excited. Protestantism and national independence were forced into connection, and it became the inevitable duty of Elizabeth on her accession to play her part as the supporter of this twofold cause. With the aid of her great minister Lord Burghley, she acted with consummate ability. Far too weak to oppose at once the powerful forces of united Catholicism, she contrived by a temporising policy to avoid the dangers which would have attended an open defiance. She took advantage abroad of every opening for indirect support of the Protestant cause; at home, skilfully mingling politics and religion, without direct religious persecution she treated her opponents as traitors. She encouraged with all her woman's wit the feeling for nautical enterprise which was rife in the country; and at length, with the obstacles which had met her early course removed, firmly seated on her throne, and regarded both at home and abroad as the champion of Protestantism, she was able to bid defiance to the power of Spain and establish the supremacy of the English navy in the repulse of the Spanish Armada.

In carrying out the sweeping changes of his reign, Henry VIII. had found the support of his people necessary. Even the settlement of the succession, though intrusted to Henry and carried out according to his wish, was arranged with parliamentary sanction. The co-operation of the people was still more necessary for Elizabeth. Throughout her reign the influence of parliament had been rising. Social changes had still further tended in this direction; if the old nobility had chiefly disappeared, a new nobility had taken its place, and the gentlemen of England, with property often increased from the monastic spoils, had become an important class. Though Elizabeth constantly assumed a masterful position with regard to her parliaments, she none the less listened to them and at times yielded to their remonstrances. It remained for the House of Stuart to force by unwise opposition this rising power into a position of supremacy. The death of the Virgin Queen seemed likely to open the question of the succession, but the crown passed without difficulty to the Scottish king, and the long-delayed union of the two kingdoms under one ruler was accomplished. The parliamentary settlement of Henry VIII. had set aside the Scottish line; it was therefore by strict law of inheritance only that James found himself called to the throne. Trained in a different school of politics, and apparently succeeding by what it was the fashion of the time to speak of as 'divine right,' he failed entirely to understand the position of his predecessors. This miscomprehension of his historical position handed on to his descendants was the cause of the disasters which attended their dynasty. Conceiving themselves possessed of the powers inherent in the old English crown, and determined to make them good, they forced the nation to fight over again the battle which had already been decided in the time of the Lancastrians. The contest between personal monarchy and constitutional government was terminated only by the removal of the Stuarts from the throne. A battlefield was found in nearly every department of government. James I. himself ran counter to many of the national prejudices. Thoroughly Protestant at heart, he favoured the

new High Church party, who looked for support in a powerful crown; easily influenced by favourites, he fell in with the fashion of the monarchies abroad, and ruled through the hands of a great minister; in disregard of the wishes of the nation, he contracted a friendship for Spain, which was now regarded as the hereditary foe. But his weaknesses were not untempered by sagacity, and he succeeded in avoiding any overt breach with his people. His more obstinate son was less fortunate. From the beginning of his reign he found his parliament arrayed against him; it succeeded even in wringing from him the great Petition of Right. Weary of the struggle in which he seemed to be worsted, he believed himself strong enough to stand alone, and for some years ruled without a parliament and in disregard of the most important liberties of his subjects. Financial difficulties, caused in part by his ill-advised efforts to establish the Episcopalian form of worship in his northern kingdom, compelled him at length to seek parliamentary aid. The long-repressed discontent of the nation thus found a means of expression, and the edifice of personal government fell before it. A grudging consent to hotly pressed reforms, an unfortunate laxity in observing his promises, and unwise efforts at resuming his power drove Charles into open hostility with the people, and the country was plunged into the horrors of civil war. Revolution ran its inevitable course; the constitutional leaders of the early movement gave place to men who dreamed of much more radical changes, and whose politics were deeply tinged with religious fervour. The war brought to the surface successful generals, and in one of them was found a man who united vast practical ability with the subversive views and religious enthusiasm of the advanced party.

The parliamentary enemies of Charles, having completed their work by the execution of the king, found themselves mastered by the overwhelming ability of Oliver Cromwell. Raised to what was practically the throne, he set himself to reconstitute upon a new basis the constitutional structure which had been swept away. His large and tolerant views, and his determination to produce order, excited the hostility of the narrow sectarians who had formed the majority of the Long Parliament. By all men of conservative mind, or who shared in the loyal sentiment so prevalent among Englishmen, he was regarded with aversion. His efforts to bring well-ordered liberty out of the jarring elements with which he was surrounded failed; he was forced throughout his tenure of power to rely upon his own iron will. He succeeded in raising England to a high place among nations; it again assumed the position of leader of the Protestant interest, and again sought its allies among the enemies of Spain. But on the death of the great Protector, and at the prospect of a succession of military tyrannies, a wave of reaction swept over the country. Enthusiasm had died out, and that majority which at all times loves the old ways and prefers the easy paths of habit to the strenuous effort necessary to complete reforms insisted on the restoration of the banished house. With general acclamation, though not without some attempts to restrain his power within legitimate limits, Charles II. was brought back to Whitehall. Less arbitrary than his father, and far more capable of bending to the storm, he proved no less determined to maintain in his own way the fullness of the power he had inherited. He had to contend with much more formidable opponents. Though the full restoration of the church and crown had followed upon his accession, the Rebellion had not been without permanent results. It was impossible that the parliament which had for years been regarded as the source of government

should sink back into the position it had occupied in the reign of Charles I.; the king could no longer hope to rule without it or to raise the revenue from illegitimate sources. The reign was one long dispute. The character of Charles, licentious, extravagant, and ready to waste the national resources upon his own pleasures, afforded ample ground of complaint. Surrounded by advisers as unscrupulous as himself, he sold himself to the French king to supply his financial wants. At the instigation of his paymaster, he plunged the country into a disastrous war with its Protestant neighbour Holland, and by his mismanagement allowed the enemy's fleet to ride undisturbed at the very threshold of the capital. He tampered with the national credit, and attempted by an exercise of high prerogative to set aside the laws against the Catholics. The enthusiastic parliament elected upon his return became before the close of its long life his bitter opponent.

The assaults of the opposition, Whigs as they were now called, were directed against the Duke of York, the king's Roman Catholic brother. Nothing would satisfy them but his absolute exclusion from the throne. To bring discredit upon the Catholics they were not ashamed to lend themselves to the infamous perjuries of Titus Oates. They thought of placing the king's illegitimate son, the Duke of Monmouth, upon the throne; but their insolence defeated itself. Charles, never deficient in political insight, understood the national love for the rights of legitimacy, the dread of a disputed succession, and the sympathy with which his efforts to support his brother were regarded. He dissolved his refractory parliament, and even thought of vengeance. He drove Shaftesbury, the leader of the opposition, from the country, and assaulted the strongholds of his enemies by finding excuses to confiscate the charters of London and other great cities. The Whigs, who saw that such a step by changing the constituencies might easily change the character of future parliaments, were driven to despair. The more statesmanlike among them began to think of seeking for the assistance of the king's nephew, the Prince of Orange. Some of the wilder spirits sought for a speedier remedy in assassination. The discovery and punishment of the Rye-house Plot, and the skilful nungling of the aspirations of patriots with the atrocious schemes of vulgar murderers, for a while discredited the Whigs, and Charles died to all appearance triumphant. It remained for his brother to bring into action the deep-seated discontent which underlay the seeming success of the crown. With a want of judgment little short of judicial blindness, he proceeded in a few years to alienate every class in England. The open insurrections of Monmouth and Argyll were punished with reckless and bloody severity. The Test Acts were set at defiance, and Catholics filled the army. He maintained the shameful attitude his brother had adopted towards France. He laid his hand upon the freehold offices of the universities and the church, asserted the power of the crown to dispense with statutes, re-established the court of High Commission, called upon the clergy to read publicly his illegal declaration of religious indulgence, and established a standing army to overawe the capital. Such a series of tyrannical actions brought about the crisis. The Whig leaders betook themselves to William of Orange. This great statesman, who had devoted his life to restrain within due limits the power of Louis XIV., at once accepted with joy the opportunity of adding the strength of England to his great combinations. Protestant in religion, tolerant both by nature and by political necessity, the powerful chief of a republican government, he was well fitted to rule a kingdom torn by religious

and political faction. The heads of all the English parties had sought his aid; his mere appearance was sufficient to close the Stuart dynasty and drive James a fugitive from the country.

The nation had again entered upon the full exercise of its powers. Taught by experience, before it deposited them in the hands of the king, it formulated the liberties of the country in a great and binding charter which should at once and for ever put an end to those efforts at personal rule which had rendered its previous history so stormy. The victory of parliament was thus completed. The reign of the first parliamentary king was indeed disturbed throughout by conspiracies, and rendered unrestful by the efforts of the exiled house, and at the close of the reign of Queen Anne for one critical moment there was a possibility that the Tories under Bolingbroke would succeed in re-establishing the Stuarts; but the rapid action of the great Whig nobles thwarted the attempt, and the failure of the Jacobite insurrection in 1715 secured in accordance with the settlement of parliament the Hanoverian House upon the throne. From that time onward, through the reigns of the four Georges, of William IV., and of Victoria, what we now regard as constitutional government has constantly prevailed. The contests of parties, however severe, have been over differences of opinion of a less vital character than those involved in a change of dynasty. It has been possible, without revolution, without impeachment, to allow of the quiet and orderly change of ministers as a regular part of the working of the parliamentary machine. Such a process implies little short of the complete disappearance of the personal wishes or opinions of the monarch as a factor in the political life of the nation. It was not without resistance that the crown consented to assume this attitude. Neither William III. nor the statesmen who had secured his accession understood the full results of what had been done. Nor was William himself, bent upon using the wealth of his new dominions to aid him in his great continental schemes, inclined to resign any of the powers of the crown or to throw himself into the arms of a single party; he attempted, like his predecessors, to employ as his ministers the ablest men of all parties. It was almost by accident that what is known as 'party government,' by which the king chooses his ministers from the majority in the House of Commons, and thus puts himself in harmony with his parliament, was discovered. The lesson which the success attending the great Whig government of 1696 taught was strengthened by experience. It was not till the Duke of Marlborough, the heir of the views and objects of William, found himself supported by the homogeneous ministry of 1708, that he met with unqualified success. From that time the ministry, virtually a committee of the majority of the house, and known as the Cabinet, has formed a recognised part of the machinery of government.

But it was not only in the establishment of constitutional government that the Revolution of 1688 produced a change in the attitude of England. It introduced the country as a first-rate power into the politics of Europe; no important complications have since arisen in which it has not played its part. Throughout William's reign, as a matter of course, its strength was employed against France. The war of the Spanish Succession opened to its armies under the leading of Marlborough a glorious career of victory. The Whig leaders, who had not shrunk from impeaching the authors of the Peace of Utrecht which closed it, yet appropriated the advantages then acquired, and forced England in support of the treaty to the very head of the European powers. In the war of the Austrian Succession, the national energies, directed chiefly against

France, secured British supremacy upon the ocean, which ripened under the great Pitt in his alliance with Frederick of Prussia into the unquestioned command of the colonial world both in the east and west. Though paralysed for a moment by the disasters of the American rebellion, the military enterprise of the country revived under the younger Pitt. Forced into opposition to the French Revolution, he was the soul of the great coalitions by which the proselytising vehemence of the Jacobins was held in check. The appearance of Napoleon upon the scene, and the extraordinary successes which attended his arms, changed the character of the war; it became a struggle for existence. It was again English subsidies, English troops, and English successes in Spain which tended more than anything else to bring the great powers into action, and to rouse that feeling of national life which produced the overthrow of the Napoleonic empire. Once again England stood at the very head of European powers.

One cause of these vast successes, unexpected in a country under popular rule, is to be found in the character of the government which sprang from the Revolution. That event was in its essence an aristocratic rather than a popular movement. The restriction of the constituencies and the influence of the possession of land threw power into the hands of a comparatively limited class. It was more as an oligarchy than as a democracy that England was able to prove itself so powerful abroad. But great social changes were gradually working themselves out, a revolution was taking place in the industrial world. The enlarged application of steam, the invention of machinery, improved methods of agriculture, the extended use of coal, the removal of the iron trade from the south to the north, and its great increase, were all tending to bring into greater prominence the trading, manufacturing, and artisan classes. The strange anomalies of the representation became still more glaring; change of occupation was not effected without much individual hardship, and the discontent arising from suffering was joined with that engendered by a sense of political exclusion. The ideas fostered by the French Revolution played their part in the general ferment. The determined and successful effort of the Irish Catholics to obtain religious emancipation laid bare the increasing weakness of the governing classes. And at length the leaders of the Whig party made common cause with the classes hitherto excluded from government, and, backed at once by the traders and the artisans, forced upon an unwilling parliament the great Reform Bill of 1832. From this time there has been a marked change both in the position of England and in the character of the questions which have excited public interest. Still mistress of the sea, and possessed through its colonies of an empire distributed in every corner of the globe, England has found enough to do in the preservation and improvement of this gigantic dominion, and has as far as possible abstained from interference in continental quarrels. Once and again it has shown its influence. In 1848, the year of revolutions, and in the subsequent consolidation of Italy, its sympathies were not hidden, but there was no thought of active interference. It allowed the great American republic to settle its disputes uninterrupted. It adopted the same attitude of non-intervention in the Prussian wars against Denmark, against Austria, and against France. It has only been in questions which seemed to touch the safety of its Eastern empire that it has drawn the sword. The Crimean war was avowedly for the maintenance of Turkey as a check upon Russia, which was threatening the road to India. Of the same class have been the wars in Egypt and

Afghanistan. Still more directly when India itself burst into insurrection was England called upon to interfere and engage in the victorious but terrible campaigns which marked the suppression of the Mutiny. The other wars, and they are not few, have all been connected with mercantile and colonial interests. The questions which have chiefly moved men's minds have been of a social or mercantile character. The extension of the electoral franchise, the reform of municipalities, the repeal of the corn laws, the establishment of free trade, the improvement of the condition of the working-classes, the regulation of strikes and trades-unions, a national system of education, and of late years the question of the management of Ireland, have been the points round which political interest has centred. They are the fitting questions to occupy a democracy. To that phase of political life in one way or other England is fast hastening. It has still to be seen whether under such conditions means will be found to keep together those colonies which are already to all intents and purposes independent, and to preserve to the empire the magnificent position which the gradual development of physical and political forces has secured.

This sketch excludes from its view the history both of Scotland and of Ireland; separate articles will be found under these headings. For a more detailed account of the events of each reign, and of the character and deeds of each important person, the reader is referred to special articles, at the end of which a list of authorities will be given. See the *Introduction to the Study of English History* (1881), by S. R. Gardiner and J. B. Mullinger, the second part containing a list of authorities. For special periods the following books will be found useful.

Before the Conquest.—Guest's *Origines Celticae* (1883); Pearson's *Early and Middle Ages*, vol. i. (1807); Kemble's *Saxons in England* (1849; new ed. 1876); Sharon Turner's *History of the Anglo-Saxons from the earliest period to the Conquest* (1852); Lappenberg's *History of England under the Anglo-Saxon Kings* (1845; new ed. 1880); Green's *Making of England, 449-820* (1881); Green's *Conquest of England, 758-1071* (1883); Stubbs' *Constitutional History*, vol. i. (1874); Hook's *Lives of the Archbishops of Canterbury*, vol. i. (1860); Elton's *Origins of English History* (1882).

1066-1485.—Stubbs' *Constitutional History*, vols. ii. iii. (1875-78); Lingard's *History of England*, vols. i.-v. (1819); Freeman's *Norman Conquest* (1867-70; new ed. 1877-79); Freeman's *William Rufus* (1882); Bright's *Medieval Monarchy* (1875); Sharon Turner's *Early and Middle Ages to 1307* (1853); Gairdner's *Richard III.* (1878); Hook's *Lives of the Archbishops* (1860).

**England, CHURCH OF.** The history of the Church of England, strictly speaking, does not begin till the close of the 6th century, but for completeness of survey some account of Christianity in Britain before the Saxon Conquest needs to be prefixed. There is no trustworthy information extant as to the original preaching of the gospel in the British Isles; all that is forthcoming is either conjecture or legend. To the former category belongs the theory that St Paul was the first missionary thither—an opinion which rests only upon the apostle's own mention of his intended journey into Spain (Rom. xv. 24, 28) and the statement made by his convert and friend, Clement of Rome, that in his missionary travels he proceeded as far as 'the limit of the west' (*Epist. ad Corinth.* i. 5), words which have been construed as signifying Britain, because the farthest western boundary of the Roman empire. But that they do not in fact denote anything except the Spanish peninsula (much of which lies farther west than Britain) is made all but certain by the latter alone finding mention in the reference to St Paul in the Muratorian Canon, a document of the 2d century. To the class of mere legend belong no fewer than nine distinct accounts, specifying other apostles and saints as having evangelised Britain, one only of which—that which brings St Joseph of Arimathea to Glastonbury, and makes him shrine the Sangreal there—found popular acceptance. The most tenable theory which a consideration of all the factors of the problem suggests is that Britain was evangelised from Gaul, and that rather by sporadic and intermittent action than by means of an organised mission from Lyons or any other of the Gallic churches. Gildas, the earliest extant British historian (*circa* 516-570), acknowledges that he has no information to give upon the subject, since all the documents which might have cleared the matter up had either been destroyed by the Saxon invaders, or carried out of the country by the exiles who fled before them. And this testimony serves as specific disproof of one of the legends—that which ascribes the conversion of Britain to missionaries sent by Pope Eleutherius (177-193), at the request of Lucius, king of Britain; for this story is based solely on an interpolation made in 530 into the record of the pontificate of

Eleutherius in the *Catalogus Pontificum Romanorum*, a date too near that of Gildas's history for him to have been ignorant of the fact if then credibly attested. The story of the martyrdom of St Alban, said to be the protomartyr of Britain in the persecution under Diocletian, though incrustated with mythical details, may probably contain a germ of fact, as the scene of his death was a place of pilgrimage at the beginning of the 5th century: but the first tangible historical item in the annals of British Christianity is the record of the presence of three British bishops (Eborius of York, Restitutius of London, and Adelinus of Caerleon) at the Council of Arles in 314. Others attended the Council of Sardica in 347, and that of Ariminum in 360. And from this time forward we find definite allusions to a settled church in Britain made by writers such as St Chrysostom, St Jerome, and Sozomen.

At the beginning of the 5th century, Pelagius (Morgan?), a native of Britain, originated the heresy which bears his name, and it spread so rapidly in his own country that his opponents were obliged to invoke the assistance of the Gallican Church against it. Accordingly, Germanus, Bishop of Auxerre, and Lupus, Bishop of Troyes, were sent in 429 to combat the new heresy, and Germanus paid a second visit with the same object in 447.

This controversy exactly synchronises with the earliest Saxon invasions, which, though carried on unsystematically by detached bands of adventurers, met with no effective resistance, and gradually overthrew the Romano-British civilisation, forcing the native population steadily, if slowly, back into the western parts of the island, apparently extirpating the church and Christianity itself in the process of conquest. Thus England forms the sole exception to the rule visible in all other parts of the Roman empire, that the Teuton invaders submitted to the creed of the conquered, and adopted as much of their civilisation and polity as they were capable of assimilating.

But what the British Church failed to effect, perhaps even to attempt, was achieved by external agencies. Kent, the oldest kingdom of the Heptarchy or Octarchy, was also the earliest to receive the gospel; and Bede's picturesque narrative tells how Gregory, Archdeacon of Rome, was attracted by the appearance of some fair-haired Saxon slave-children exposed for sale in the forum, and on inquiry into their race and country was seized with a desire to become a missionary thither. He could not obtain the necessary sanction, because his services at home were too valuable to be dispensed with; but when he was elected pope he determined to take effectual steps for carrying out his original plan with other instruments. He chose Augustine, prior of St Andrew's monastery on the Coelian Hill, a foundation of his own, as head of the mission he projected, and sent him, accompanied by forty monks of the community, with supplies and with letters of recommendation to the bishops and sovereigns of Gaul. This policy directed the course which the mission was to take, for Charibert, king of Paris, had given his daughter Bertha in marriage to Ethelbert, king of Kent, though a heathen, on condition that she should be permitted the free exercise of her religion, and be attended by a body of domestic chaplains. Ethelbert accepted the conditions, and repaired a ruined Christian church just outside Canterbury for their use, and was thus likely to receive Christian missionaries more readily than any other of the Anglo-Saxon kings. Moreover, he held the honorary precedence amongst them denoted by the title of Bretwalda, so that his example, if he could be induced to encourage the strangers,

would be exceptionally influential throughout the country.

Augustine and his companions landed in Thanet on August 7, 596, and were granted an audience by the king in a few days under a great oak, to which they advanced in procession, preceded by a silver cross, bearing a picture of Christ, and singing the Litany. They were favourably received, and given permission to preach and make converts of such as chose to listen to them, while Ethelbert himself, about a year after the arrival of the mission, accepted their teaching, informed the Witan of his proposed change of religion, and obtained its sanction, besides inducing several of its members to follow his example, as did also great numbers of the commons. Hereupon Augustine, in compliance with directions given him by Pope Gregory before his departure from Rome, went to Gaul to obtain episcopal consecration as Archbishop of the English, which he obtained at the hands of Virgilius, Archbishop of Arles (November 16, 597). He sent news of his success to Rome, asking for additional men and supplies, which were promptly sent, together with the distinction of the archiepiscopal pall for Augustine himself, and a commission empowering him not only to erect twelve suffragan sees in southern England, but to do the same in the north, and appoint any one he pleased as metropolitan over them at York. But in fact little solid advance was made outside Kent for a considerable time, since a conference between Augustine and representatives of the British Church broke down through prejudice and misapprehension on both sides; and the apparent success which attended the missions in the kingdoms of Essex, Mercia, East Anglia, and Northumbria proved unsubstantial, for even those of them which had been most unanimous in accepting the gospel relapsed into heathenism after the death of the convert kings.

The recovery of these regions is due to the Celtic missionaries from their headquarters at Iona, an Irish colony, and notably to Aidan and his successor Finan. All northern and central England was evangelised by their agency, and also Essex, so that about two-thirds of the whole area of the country owes its Christianity to this source. The remainder is thus accounted for: East Anglia was converted by Felix, a priest from Burgundy, whom Augustine then raised to the episcopate; Wessex, by Birinus, an Italian, who obtained a mission from Pope Honorius, independently of St Augustine's, in 634; and Sussex, the last part of England to receive the gospel, by Wilfrid, Bishop of York, then exiled from his own diocese (681-685), the Isle of Wight being actually the latest scene of conversion. No difficulty was raised by the Scotch-Celtic missionaries in accepting the primacy of Canterbury, and in fact the several missions were welded into a single church during the life of Theodore, seventh Archbishop of Canterbury, who sat from 668 to 693. He it was who at the Synod of Hertford in 673 broke up the existing dioceses, each of which was continuous with one of the Saxon kingdoms, into sixteen more manageable areas, all of them suffragan to Canterbury. In 735 York was made an archbishopric and metropole of the northern part of the island, though with precedence after Canterbury; but this distinction was not given formal expression until 1093, when the title 'Primate of All England' was attached to the holder of the latter see. The Welsh Church remained separate for a much longer time than that of Northumbria. It is not till 875 that there is proof of the intervention of Canterbury within its limits, for which the lack of any Welsh metropolitanate gave the occasion, and not till 1188

was the union with the Church of England fully effected.

Save for the sufferings inflicted during about a century by the piratical invasions of the pagan Danes, who treated the Saxon Christians much as the British Christians had been treated by the forefathers of those Saxons, the Anglo-Saxon Church remained peaceful and undisturbed till the Norman Conquest, living a life of its own, having scarcely any intercourse or relations with the continental churches, and ministered to by an episcopate and clergy with slender claims to learning, culture, or activity.

The Conquest, albeit attended with much hardship and oppression of the subjugated nation, and with some extrusion of Saxon prelates the moment William felt himself firm on his new throne, proved almost an unmixed benefit to the church of the country. The Norman clergy, while no less devout than the most pious Saxons, were far their superiors in learning and intellectual gifts, and the men whom William intruded into the places of the deprived Saxons, whether as bishops or abbots, were for the most part of high mark, in proof of which it will suffice to name Lanfranc, Archbishop of Canterbury, Osmund, Bishop of Sarum, and Anselm, Lanfranc's successor, though his accession to the primacy was under William II. in 1093. The great Norman nobles as a rule exercised their patronage with similar discernment; they founded abbeys and churches, cathedral and parochial, larger and statelier than had been known in England; they invited over monks from the most celebrated foreign monasteries to occupy the new foundations, and they brought the English Church, after several centuries of virtual isolation, again into touch with the rest of Latin Christendom. One factor in this last change, however, had results which no one could then forecast, for it was the Conqueror himself who availed himself of the opportunity given by the abortive Saxon revolt of 1066 to depose the Saxon primate Stigand. For this purpose he invoked the assistance of the pope, who sent two cardinals as legates. Under their presidency a synod was held at Winchester in 1070, wherein the deprivation of Stigand was effected, and the first precedent established for the internal jurisdiction of the papal authority in England. When William's own strong personality was removed, difficulties at once arose from this cause, as in the disputes concerning the investiture of bishops between William II. and Henry I. on the temporal side, and St Anselm upon the ecclesiastical part, which ended in a compromise whereby the king abandoned the claim to invest bishops by the delivery of the pastoral staff and the episcopal ring, and the church agreed not to treat the act of homage on the part of a bishop-elect as disqualifying him for consecration. This was a practical victory for the civil power, and the beginning of that mode of its nominating English bishops by uniting a letter-missive in favour of a specified person to the *congé d'élire*, or license for election, which still prevails.

Graver troubles arose when Henry II. endeavoured to abolish the privilege of clergy, which exempted all members of the clerical body from the jurisdiction of the civil courts, even for the most serious offences against the laws. He availed himself of a vacancy in the see of Canterbury to nominate his chancellor, Thomas Becket, to the primacy, in the expectation that he would assist in bringing about this desired change. At first the new archbishop gave some support to the plan, but at the Council of Clarendon, where the new laws were synodically voted, he refused to validate the acts of the council by affixing his official seal to them, to the great anger of Henry, who was present, and who imme-

diately took action which drove Becket into exile for six years. On his return to England, he excommunicated the Archbishop of York, the Bishop of London, and the Bishop of Salisbury for usurping his functions during his absence, and they at once proceeded to Normandy to complain of him to the king. The hasty words which the news drew from him were caught up by four knights of the court, who hurried over to England, and murdered the archbishop in his own cathedral. The crime proved fatal to the proposed measures, which Henry was compelled to abandon; and though some limitation of the privilege of clergy took place in the reign of Edward III., and again in that of Henry VII., it was not till the Reformation statutes of 1536 and 1541 that it was finally abolished.

The Papacy was even more successful in the reign of John than in that of his father. The pope then was Innocent III., one of the ablest and most ambitious of the Roman pontiffs, who set aside a disputed election to the see of Canterbury, and appointed Cardinal Stephen Langton instead of either claimant. The king refused to accept the nomination of Langton, and the pope at once put the kingdom under an interdict, which involved the cessation of the offices of religion throughout the country. But as John proceeded to retaliate by acts of violence against the clergy, a sentence of excommunication was fulminated against himself, quickly followed by one of deposition, whereby his subjects were released from their allegiance, and the kingdom was granted to Philip, king of France, who was enjoined to invade England with an army. Although John called out a military force to resist the threatened invasion, he was afraid to trust himself to his alienated subjects, and made secret terms with Pandulf, the papal legate at the French court, in accordance with which John signed a deed of resignation of his insular dominions into the hands of the pope, to be held from him as his feudal vassal on payment of a thousand marks yearly, and actually executed this undertaking in the church of the Templars at Ewell, near Dover, in 1213, kneeling before the seated legate, laying the crown at his feet, and taking the oath of homage to the pope as his lord paramount. The exiled prelates hereupon returned, and Cardinal Langton gave absolution to the king. But although Langton was thus forced upon the country by external influence, he at once identified himself with the popular party, headed the confederacy of the barons formed to extort reforms from John, disregarded the pope's attempt to protect his vassal, and compelled the signature of the Great Charter at Runnymede in 1215, refusing to publish the bull with which Innocent III. attempted to quash it. Nevertheless, the vassalage of the kingdom was not suffered to remain a mere dead letter of titular dependence on the Papacy; it continued as a very potent fact during the long reign of Henry III., when the church patronage was almost monopolised by the popes, in virtue of 'mandates' and 'provisions,' and exercised chiefly in favour of Italians; while the revenues drawn to Rome from England, as vouched by a complaint lodged at the Council of Lyons in 1274, largely exceeded those of the crown. This policy, which at once affected the people generally in their religious relations throughout the parishes all over England, and the state in its corporate character, did much to beget a temper of revolt against the Roman claims, as those of an alien and even hostile power, and had much to do with the spread of Lollardism at a somewhat later period, and even with the permanent success of the Reformation.

There was, however, an event of a very different

kind which also marked the 13th century: the introduction of the new institute of friars, then but lately founded by Francis of Assisi and Dominic Guzman on a basis differing in several important particulars from the older monasticism which had played so great a part in church history. The Dominicans, or Friars-preachers, reached England about 1219, the Franciscans about 1224, being soon followed by the Carmelites and Augustinians. For a time they worked as marked a revival as they had already brought about in religion on the Continent, and the Franciscans became in addition famous for their learning, not only furnishing the ablest teachers to the universities, but producing men of such exceptional eminence as Roger Bacon, Duns Scotus, and William of Ockham. For a time the influence of the friars was wholly healthful and stimulating, but the very popularity which they enjoyed crowded their ranks with unworthy members, and the greed which they soon evinced, as well as the anti-national attitude they assumed in consequence of their exemption from local jurisdiction, as holding directly from the pope, so that they viewed themselves as his liegemen and acted as papal garrisons in England, marred the fair promise of their advent, and made them additional factors in the growing alienation from Rome. This change of attitude towards the friars appears as early as the episcopate of Robert Grosseteste, Bishop of Lincoln (1235-53), who had been one of the first to welcome their arrival, but became their steady opponent towards the close of his life, as he also was of the papal usurpation of English church patronage.

Edward I. renounced that fealty to the Papacy which his father and grandfather had accepted, besides checking the transfer of land by the Statute of Mortmain in 1279; and his own grandson, Edward III., carried resistance much further—in 1350, by the Statute of Provisors, which put an end to the pope's encroachments on the rights of patrons; in 1353, by forbidding appeals to Rome under pain of outlawry; in 1367, by refusing to continue payment of the tribute with which John had saddled the kingdom; and in 1374-75, by an inquiry into the number and value of the benefices occupied by aliens, succeeded by an embassy to the pope to complain of the abuses. One member of that embassy, John Wyclif, Master of Balliol, Oxford, had a powerful, if temporary, influence in fostering opinions adverse to the current system, and the popularity of his translation of the Bible contributed much to the same end. His teaching, though officially condemned both by the university and the church, found many supporters both amongst the educated and the masses, and probably helped the enactment of the Statute of Premunire in 1393, as it certainly did the spread of Lollardism after his death in 1384. Active measures were taken for its repression under Richard II. and Henry IV., and the first execution by burning for heresy in England was that of William Sawtre, a London rector, in 1401. He was the earliest of many victims (including Sir John Oldcastle, Lord Cobham) during a persecution which lasted with little intermission till the outbreak of the Wars of the Roses; but meantime the reaction against Rome was holding its course both in church and state, and was much increased by the high-handed action of Pope Martin V., who endeavoured to revive the abuses which successive kings and parliaments had abated or removed.

Some recovery of Roman influence, however, took place in the weak reign of Henry VI., and Cardinal Kemp, Archbishop of Canterbury, was not only nominated by the pope to the primacy, but avowedly governed the church as papal legate; a policy

wherein he was followed by his successors Cardinals Bouchier and Morton, under the last of whom (1487-1501) the long struggle of the nation against papal encroachments seemed to end in final defeat, and in the reduction of England to a mere appanage of Rome. With the accession of William Warham, a patron of learning, to the primacy in 1502, some abatement of this subjection becomes visible; but the time for a far wider and deeper revolt was near at hand, seeing that the Lutheran movement, destined to influence the whole Western Church, took place during Warham's primacy, and rapidly affected even those who were most opposed to its principles. In particular, the widespread anger it aroused against practical abuses strengthened the hands of Cardinal Wolsey in undertaking the reform of the monastic houses in England, by purging the greater monasteries of their scandals, and suppressing small and useless foundations, drafting their inmates into the larger societies, and applying their revenues to educational purposes. But rougher hands were to carry on the work in a very different fashion from his temperate measures. The failure of Henry VIII. in obtaining a divorce at the pope's hands from his queen, Catharine of Aragon, since her nephew, the Emperor Charles V., was too powerful to be thus braved, led to his determination to break with Rome; and though Wolsey declined to assist his plans, and was disgraced in consequence, yet in Thomas Crommer, whom, on Warham's death in 1532, he raised to the primacy, he found a ready instrument for his purpose. Crommer declared the marriage with Catharine void, and the king's private marriage to Anne Boleyn valid; while Henry resorted upon the pope's verdict of 1534 against this union by hastening on the proceedings of the famous 'Reformation Parliament,' which continued from 1529 to 1536. Herein papal licenses and bulls were prohibited, the king's ecclesiastical supremacy declared the law of the land, and its impugnment punishable with death; the submission of the clergy, compelling them to accept a revision of the canons by a royal commission and to assemble in their convocations only when summoned by the king's writ, was extorted; the payment of annates to Rome was forbidden; and the statute in 'Restraint of Appeals,' terminating all ecclesiastical suits within the kingdom by prohibiting the carriage of any suit before the pope, was enacted.

These changes seem to have been received, not only without resistance, but with real approval, even by the clergy as a whole; and, except for the breach with Rome, little alteration was made in the ordinary routine of church teaching and discipline, though some slight advance was made in the reforming direction by the issue of the Ten Articles in 1536 and the *Institution of a Christian Man*, or *The Bishops' Book*, in 1537, recast and re-issued in 1542 as the *Necessary Erudition of a Christian Man*, or *The King's Book*. A greater practical change was carried out by the wholesale spoliation and suppression of the monasteries, mainly by the agency of Thomas Cromwell between 1536 and 1539, and the devolution of their great revenues, including the inappropriated tithes of parish churches, into the hands of the king and the secular landlords. The Act of the Six Articles in 1539 was aimed at the more advanced Reformers, and made several of their favourite tenets heresy at statute law, so that it was no longer possible for the accused to save his life by abjuration, as it had been under the previous system. Some modification of its severity was made in 1543 and in 1544, and the beginnings of vernacular services appear in the publication of the Litany in English, in addition to an earlier permission for the private use of the Psalter, Creed, Lord's Prayer, and Hail

Mary. Such was the posture of affairs at the death of Henry VIII. in 1547.

Under the child-king Edward VI., the reforming movement was pushed on much more rapidly, and is sharply divisible into two distinct periods: an earlier one, whose landmarks are the Order of Communion of 1548, and the First Book of Common Prayer in 1549, both of them the work of the native clergy, and drafted on mainly conservative lines; and a later one, when the influence of the foreign Reformers domiciled in England, and notably Bucer and Peter Martyr, became dominant with the king's advisers, and resulted in the destruction of the altars of the churches in 1550, the issue of the Second Prayer-book in 1552, by royal and parliamentary authority only, and without the assent of the church, and the compilation of the Forty-two Articles, the first draft of the present Thirty-nine, in 1553. So much wanton havoc had been wrought under colour of reformation in the closing years of Edward's short reign that Mary's accession was received without alarm, and even with welcome, and that by the clergy no less than by the laity, with the exception of those who felt themselves imperilled. But though she immediately set herself to undo all the work of the preceding quarter of a century, aided by her husband Philip II. and her kinsman Cardinal Pole, so that she was enabled with the assent of parliament to bring the church and nation back into the relations with the see of Rome which had prevailed up to 1529, yet her impolitic cruelties and the fierce persecution of which Crommer, Ridley, Latimer, and Hooper were the most conspicuous victims, alienated the national sympathies from her, and led to a fresh reaction, which at once took shape under her successor Elizabeth. In 1559 the Act of Uniformity re-establishing the Common Prayer-book, and also a statute reviving the royal supremacy, were enacted; the Thirty-nine Articles were published in 1563, and the Church of England placed in a position midway between the attitudes in the two periods of Edward VI.'s reign already referred to. The Marian bishops, who refused to accept the changes, were deprived, but not otherwise harshly treated, and only 189 of the whole clerical body, inclusive of these fourteen prelates and six abbots, out of a total of 9400, declined to conform; while there was no separatist Roman Catholic body in England till after Pius V. issued his Bull of Excommunication against Elizabeth in 1570, nor were they organised in anywise till 1598. See ARCHPRIEST.

The Puritan section in the country, however, was far from content with the amount of reform achieved, and quickly came into collision with the authorities in church and state, mainly upon minor details of ceremonial. The first secession on these grounds took place in 1563, and was generally condemned by the leading foreign Reformers; but nevertheless Puritan principles spread very fast, and became powerful in parliament, though not sufficiently so to prevent the enactment of a severely repressive statute in 1593, when the Puritans' own violence and intractability had provoked a reaction against them, and they remained quiescent during the remainder of Elizabeth's reign. They revived in activity under James I., and had high hopes of success; but the Hampton Court Conference, wherein an attempt was made to arrive at an amicable understanding between them and the church, proved abortive; and while their disciplinary proposals were choekmated by the Canons of 1604, their doctrinal aspirations were even more effectually and permanently defeated by the rise of the Anglo-Catholic school of theology, which exchanged the destructive and innovating tempo which had inevitably prevailed during the crisis of the Reformation, when the removal of abuses was the main

object, for a constructive and conservative one, making constant appeal to the standards of the ancient undivided church, and being especially opposed to the tenets of Calvinism and Zwinglianism. But the king's feebleness of nature made him ill able to guide the country at such a time, and his political blunders brought about an alliance between the Puritans and the patriot party, who were aggrieved by many acts of misgovernment. The authorities of the Church of England, contrariwise, both under James and his successor Charles I., lent themselves to the support of absolutist views, and thus incurred much odium, which was considerably increased by the dissatisfaction aroused by the action of Archbishop Laud, whose good intentions were not accompanied with practical discretion, but were marked with much high-handed intolerance. The reaction was swift and violent: the Westminster Assembly of Divines met in 1643, and adopted from Scotland the Solemn League and Covenant, one detail of which is the total abolition of prelacy, and which parliament made binding on all persons in England over the age of eighteen; in 1645 the Book of Common Prayer was forbidden under severe penalties, and the Directory of Public Worship substituted for it; in the same year Archbishop Laud was brought to the block, and the Church of England, as a body holding a recognised national position and free to exercise its functions, disappeared from view for the fifteen following years. The restoration of Charles II. in 1660 was attended by the return of the exiled clergy and the reinstatement of the church, while the Savoy Conference in 1661 decided the issue as to the general aspect of the revived communion in favour of the High Church or Anglo-Catholic view, by revising the Prayer-book in its present form, which was enforced by an Act of Uniformity in 1662, a measure followed by the resignation of a number of the ministers admitted to benefices under the Commonwealth, estimated variously at from 800 to 2000. This was virtually the last settlement of ecclesiastical affairs in England by the joint action of church and state, and the many events which have since occurred to condition them have not materially altered its broad features. The illegal exercise by James II. of a dispensing power in issuing the 'Declaration of Indulgence,' which, though ostensibly meant for the relief of all Nonconformists, was designed to cover the legalisation of Roman Catholicism, and the trial of the seven bishops who refused to give it circulation in their dioceses, directly caused James's deposition, and resulted hurtfully in some respects for the church.

For the Nonjuring schism under William III. deprived the church of many pious and some able men whom it could ill spare, and contributed something to the gradual cooling of zeal and the laxity of doctrine which marked the Hanoverian period and were furthered by the influence of such prelates as Hoadly and White Kennett. But socially the Church of England touched its highest point of influence just before the season of decay. At the close of Queen Anne's reign it appeared to be strong and successful everywhere, and there was practically no competitor in the field, as both Roman Catholics and Nonconformists were few and powerless. But with the silencing of Convocation under George I. in 1717 (made feasible by its impolitic surrender in 1664 of the right of the clergy to vote all taxes payable by them), and the steady encouragement given to the ultra-Broad Church section of the clergy, a blight came upon the church, and it rather vegetated than actively lived thenceforward till nearly the close of the 18th century; for the Methodist movement, begun by John and Charles Wesley in 1727 on the footing of

a guild within the church, and given formal shape in 1740, began to assume the status of an external sect in 1760, and soon afterwards became the active rival of the church. The Evangelical revival towards the close of the century owed much of its success to the alarm caused by the French Revolution, since the adoption of freethinking opinions in England was thought likely to lead to results similar to those of the Terror; but though it did much for individual piety, the notion of working in and for the church at large, or as a national institution, does not seem to have so much as crossed the minds of its leaders, and it did thus nothing whatever to promote any corporate reforms, though achieving much in raising the standard of clerical devoutness.

It was reserved for the factor variously known as the Oxford or Tractarian movement, or by its advocates as the 'Catholic Revival,' to make this omission good, and to stimulate the energies of the whole Anglican communion. The movement itself was immediately occasioned by a statute enacted in 1833 suppressing ten bishoprics in the Church of Ireland, which at once prompted the question, 'If the like policy should at any time prevail in England also, and lead to the overthrow of the church as an establishment, what would it have to fall back upon for its very existence as a corporate body?' The answer to this question was given in the 'Tracts for the Times,' issued from Oxford at intervals during 1833-41, and chiefly written by Newman, Keble, Pusey, Isaac Williams, and Richard Hurrell Froude. They at once excited active controversy, seeing that they not only traversed the Low and Broad Church positions, but also that of the contemporary High Church school itself, which was content to acquiesce in a theology bearing clear marks of 18th-century influence, and differing materially from that of the great Stuart divines, which the Tract-writers aimed at reviving. Although at first the line adopted by the school as a whole may be roughly described as a *via media* between Roman Catholicism and Reformation doctrines, although at first the former system was freely criticised, yet two great waves of secession to the Roman Church, in 1845 and 1850, the earlier occasioned by the condemnation of Tract XC., written by Dr Newman, and the latter by the Gorham Judgment, drew considerable numbers of its more distinguished members with them, and not only weakened it seriously at the time, but seemed to justify all the adverse criticism it had met, and to discredit it altogether. Nevertheless, it stood the shock firmly, and proceeded on the lines originally sketched out, and that with such energy and success as to entirely change the face of the Anglican Church during the succeeding half-century. The great development of church building and restoration, the revivals of convocation and of sisterhood life, the creation of a copious and learned ecclesiastical literature, the impetus given to the foundation of colonial and missionary dioceses and to the increase of the home sees, at first merely suffragan, but later as separate dioceses, the introduction of a higher standard of clerical life and work, and the embellishment of public worship, are the chief results of its labours; and what might have been less anticipated from its origin, it has shown itself not less ready in adapting agencies of nonconformist birth and usage to the purposes of the church. That it has in fact been the determining factor in these respects, and has rather drawn the remaining schools into the current than been anticipated or aided by them, is vouched by the date, not less than by the character, of the reforms, since they do not begin to be manifest, even in germ, till the Oxford movement became powerful, and was translated from theory into

practice. As regards the alleged tendency towards Roman Catholicism, that must be judged not by the degree in which the school is in sympathy with Roman Catholics rather than with Protestants on certain issues, nor yet by counting up individual secessions in that direction, but by the broader inquiry into the growth of the Roman Church in England since the Oxford movement has affected the condition of religion in the country. And the fact is, as attested alike by the marriage returns (especially trustworthy in the case of Roman Catholics, because of their strict discipline in this matter) and by the calculations made by the Roman Catholic authorities themselves, they do not increase at the same rate as the nation at large, and constitute, despite their threefold sources of increase—births, immigrants, and conversions—a slowly but steadily diminishing factor in its ratio to the population, and chiefly dependent, even so, upon the Irish element to maintain its numbers.

In marked contrast with the torpor of the last century and the earlier years of the present one, the history of the Church of England for fifty years past has been as crowded with events profoundly affecting it as any corresponding period of time during the Reformation era; with this notable difference, the absence of the Erastian character which the direct intervention of the crown and the civil power in general gave then to the aspect of ecclesiastical affairs. In the modern revival of the Church of England the court has had neither share nor sympathy, there has been rather more opposition than aid from parliament, owing to the temper of the large nonconformist element in the House of Commons, and the legal tribunals have been actively hostile; but no serious check or delay has been interposed to the movement by any or all of these adverse influences. It is possible to name only the most salient events of the half-century in the briefest fashion to complete this historical outline. The beginning of Queen Victoria's reign was marked by the enactment of the Pluralities and Non-residence Act in 1838, and of the Church Discipline Act in 1840. The development of the colonial episcopate (which, though initiated in 1787, had increased to no more than five sees down to 1836) began in 1841, and was steadily rapid in operation. The Gorham case, decided against the ruling of the Court of Arches by the Judicial Committee of Privy-council, synchronised with the establishment of a Roman Catholic hierarchy in England by Pius IX. in 1850, professedly as a restoration of the pre-Reformation episcopate. Convocation was revived in 1853, through the action of Lord Aberdeen, then premier, and has met regularly ever since. In 1860 *Essays and Reviews* was published, and was soon followed by kindred but bolder writings of Dr Colenso, Bishop of Natal; and though both the *Essays* and the bishop were condemned by the ecclesiastical authorities, these sentences were reversed, the former in 1864, the latter in 1865, by the Judicial Committee; against which findings strong protests were made (in the case of *Essays and Reviews* by 11,000 clergymen), and the Convocation of Canterbury affirmed synodically the contrary condemnations. The Church Congresses, which have done so much to make the outer public familiar with the working of the English Church, began in 1861; the Pan-Anglican Conferences, equally powerful in welding together the separated parts of the vast Anglican communion, in 1867. Contrasting with the license allowed to the Low and Broad Church schools by the Privy-council decisions, the judgment in the suit of Liddell v. Westerton (1857) was largely, and those in the suits of Martin v. Mackonochie (1869), Ibbert v. Purchas (1871), and Clifton v. Ridsdale (1877), were entirely, hostile to the High Church liti-

gants, condemning various ceremonial adjuncts of public worship which they held to be permitted or enjoined by the formularies. But these findings have been so riddled with destructive criticism by eminent jurists and other experts as miscarriages of justice that they have never commanded respect or obedience, nor has the imprisonment of some of the clergymen affected been found to deter others from pursuing the same course. Indeed, the failure of the suit of Sheppard v. Bennett (1872), instituted for the purpose of excluding the tenets supposed to underlie the condemned ceremonial usages from toleration within the Church of England, deprived them of the only plausible defence which could be set up for them, that of the ultimate inconsistency of those usages with the dogmatic standards of the church. The restoration of the long dormant class of suffragan bishops took place in 1870, and they now form a considerable factor in the home episcopate; while the increase in the number of English dioceses, originating with the foundation of the sees of Manchester and Ripon in 1836, was promoted by the passage of a bill for that purpose in 1878, which has been acted on by the erection of the sees of Liverpool, Newcastle, St Albans, Southwell, Truro, and Wakefield.

The polity of the Church of England is episcopal, and the area is territorially distributed into two provinces, Canterbury and York, each presided over by an archbishop, having severally twenty-three and nine dioceses subject to their jurisdiction, in several of which there are suffragan bishops acting, making the number of employed bishops about forty. There are about 13,500 benefices, and the whole body of the clergy, inclusive of those unemployed, is estimated at 23,000 members. The gross income of the church from all sources is roughly estimated at about £7,250,000, and the church accommodation at 6,250,000 sittings. The colonial dioceses and missionary jurisdictions in connection with the English Church are 65 in number, with about 80 bishops and 3400 clergymen; and of the allied sister or daughter churches, that in Scotland has 7 bishops and 266 clergymen; that of Ireland, 2 archbishops, 11 bishops, and 1773 clergymen; that in the United States, 71 bishops, and about 3300 clergymen; making, exclusive of retired bishops, a gross total of 211 bishops and 33,000 clergymen. The Church of England claims that its bishops are the legitimate and canonical successors of the pre-Reformation hierarchy, and has carefully fenced the episcopal office with safeguards to insure its regular continuance. But Roman Catholic controversialists allege that there was a complete solution of continuity at the accession of Elizabeth, when Matthew Parker was appointed Archbishop of Canterbury in the room of the recently deceased Cardinal Pole. Yet not only has the regularity of the English succession been acknowledged by such eminent authorities as Bossuet in the past and Dollinger in the present day, but there is decisive proof that the objections now alleged are merely factitious afterthoughts. The question of the necessity of papal confirmation to validate the status of bishops was debated in the Council of Trent, November 30, 1562, and objections were adduced against its obligation. But it was argued on the other side that to rule against it would be dangerous, because the only argument admissible against the orders of the English bishops was that they had not papal confirmation, since they proved that they had due call, election, mission, and consecration; and the whole council accepted this view of the situation (*Le Plat, Monum. Conc. Trident.* dcclxxi.).

The doctrinal standards of the Church of England are primarily the Book of Common Prayer, including the three Creeds occurring therein; and

secondly, the Thirty-nine Articles. The first four general councils are also part of her legal system, and there is a general appeal to Holy Scripture as interpreted by 'the Catholic Fathers and ancient bishops.' She differs from the Roman Catholic Church by the rejection of the distinctively Roman tenets embodied in the modern articles of the Creed of Pope Pius IV., and from the Eastern Church in a less degree, and chiefly in respect of the invocation of saints and the cultus of images, as not warranted either by Scripture or by the church of the first five centuries. On the other hand, she differs from the societies which have sprung up since the Reformation by requiring episcopal ordination for all her clerical members; by the structure and tone of her Liturgy, which is simply a translated and abridged revision of the pre-Reformation Missal, Breviary, and other office-books; and by her refusal to admit into her formularies any tenets which have not the warrant of antiquity, whatever plausible arguments may be adduced for them from the letter of Scripture. She has always exercised strong attraction upon the educated classes, and has probably a larger proportion of cultured laymen actively interested in and working for her than any other communion of the day, and in England she has also retained the agricultural class. But the lower middle class and the town artisans have been less influenced by her, and, in fact, constitute the strength of English Nonconformity. The revival of the last fifty years has, however, begun to tell upon this class also, and nearly every large town can show congregations formed of such materials; while the advance of the daughter-church in the United States is notably rapid and permanent.

The most convenient books for the student to consult upon the history and position of the Church of England are Perry, *Student's English Church History* (1878); Dixon, *History of the Church of England from the Abolition of the Roman Jurisdiction* (1877-85); Abbey and Overton, *The English Church in the Eighteenth Century* (1878); Sadler, *Church Doctrine, Bible Truth* (1872); Bishop Christopher Wordsworth, *Theophilus Anglicanus* (1885); Curtis, *Bampton Lectures on Dissent in its Relation to the Church of England* (1872); Howard, *The Church of England and other Religious Communions* (1885); Moore, *Englishman's Brief on Behalf of his National Church* (S.P.C.K.); Bishop Forbes, *Explanation of the Thirty-nine Articles* (1878).

**English Language.** *Periods.*—Great as are the changes that separate the oldest English from the English of the present day, these changes are so gradual and so continuous that no definite lines can be drawn. But it is easy to discern three main stages of development: *Old English* (O.E.), *Middle English* (M.E.), and *Modern English* (Mn.E.), each subdivided into an *early* and a *late* period. There are besides two marked periods of *transition* between the main periods. The chronology of these periods is approximately as follows:

Early Old English (Alfred period).....	700-900
Late Old English (Ælfrie period).....	900-1050
First Transition (Layamon period).....	1050-1150
Early Middle English (Ancren Rible period).....	1150-1300
Late Middle English (Chaucer period).....	1300-1400
Second Transition (Caxton period).....	1400-1500
Early Modern English (Shakespeare period).....	1500-1650
Late Modern English.....	1650-1900

**OLD ENGLISH.**—*Dialects.*—There were four dialects of O.E.: (1) *Northumbrian* (North.), extending from the Humber to the Forth; (2) *Mercian* (Merc.), between Thames and Humber; (3) *Kentish* (Kent.); (4) *West Saxon* (W.S.). North. and Merc. together constitute the *Anglian*, W.S. and Kent. the *Southern* group.

Literature was first cultivated in the North, and

the Angles were for a long time the dominant tribe. Hence *Englisc* ('English') came to be the collective name for the whole group of dialects, and remained so after the supremacy had passed to the West Saxons, and W.S. became the official language of the whole English people.

*Vocabulary.*—O.E. was, in the main, a homogeneous language, forming new words at will by derivation and composition. Thus 'scribes and Pharisees' were Englished as 'bookers and sundersaints' (*bóceras and sundorhálgan*). But it adopted many Latin words at different periods, some of which, such as *stræt*, 'street' (*via strāta*), it brought with it from its continental home on the other side of the German Ocean. Celtic loan-words, such as *drīȝ*, 'sorcerer,' are very rare, because those Celts with whom the English came most in contact were almost completely Romanised.

*Spelling and Pronunciation.*—On their conversion to Christianity the English adopted the Latin alphabet in its Celtic form—whence *ȝ = g*, &c.—with the traditional Latin values of the letters as preserved by the Celts. They added to it from their national Runic alphabet the letters *þ = th* and *ƿ = w*.

The O.E. spelling was as phonetic as its defects would allow. There were no 'silent' letters. Double consonants, as in *sunne*, 'sun,' were pronounced double, as in Italian; *e* and *o* had a close and an open sound—when open we write them *e*, *o*; *a* had the sound of our *a* in *man*; *y* had its original sound of French *u*. In the diphthongs *ea*, *eo*, the stress was on the first elements; *ie* (originally a diphthong) had the open sound of our *i* in *bit*; *c* had a 'back' sound = *k*, and a 'front' one, which we write *c*, nearly that of our *ch*, as in *cild*, 'child'; *c* was always front in the combination *sc*. There was a corresponding distinction between *g* and *ȝ*, as in *geard*, 'court'; *geong*, Angl. *gung*, 'young' (where it is a modification of original *j*; compare German *jung*). Double *ȝ* is written *eg*, as in *egc*, 'edge.' In *ng* the *g* was pronounced distinctly, as in *lang*, 'long.' After a vowel, *r*, or *l*, *g* had the open sound of the *g* in German *sagen*, *ȝ* that of our *y* in *young*: *dagas*, 'days'; *sorg*, 'sorrow'; *deg*, 'day.' Non-initial ('strong') *h* had the sound of Scotch *ch* in *loch*, as in *dohtor*, 'daughter'; *f*, *s*, *þ* had the voiced sounds *v*, *z*, *dh* between vowels and elsewhere, as in *ofer*, 'over.'

*Phonology.*—Original (Germanic) *a* appears in O.E. only before an original back vowel, as in *dagas*, and before nasals, as in *nama*, 'name'; *lang*. This latter *a* becomes *o* in Angl., as in *nama*. Before *r* and *l* consonant, *a* becomes *ea*, as in *heard*, 'hard'; *eald*, 'old.' Angl. restores *a* before *l*, and lengthens it: *āld*. In other cases *a* becomes *æ*, as in *dæg*; *e* before *r* and consonant becomes *eo*, as in *eorþe*, 'earth.' There is an *ē* which is common to all the dialects, as in *se*, 'sea,' and one which is peculiar to W.S., becoming *ē* in the other dialects, as in *dēd*, 'dead.' Angl. and Kent. *dād*. In W.S. *æ* and *ā* are diphthongised into *ea*, *ēa*, as in *cæster*, 'city'; *gear*, 'year' = non-W.S. *cæster*, *gēr*. W.S. *ie* corresponds to *i*, *e*, *ē* in the other dialects, as in *bierhtu*, 'brightness'; *giefan*, 'give'; *icldra*, 'elder' = Angl. *brihtu*, *gēfan*, *ēldra*. W.S. *ie* appears as *ē* in the other dialects, as in *hieran*, 'hear' = Angl. *hēran*. In Late W.S. *ie*, *ē* become *y*, *ȝ*, as in *yldra*, *hyran*. In Angl. *ea*, *eo* become *ē* before *c*, *g*, *h*, as in *ēc*, 'also'; *hēgan*, 'fly'; *hēh*, 'high' = W.S. *æc*, *flogan*, *hēah*. In Late Kent. *ȝ*, *y* become *e*, *ē*, as in *senn*, 'sin' = Early Kent. and common O.E. *synn*.

*Inflections.*—O.E. has all the characteristics of an inflectional language. It has a threefold grammatical gender. Nouns have four cases—nominative, accusative, dative, and genitive. The acc. is the same as the nom. in all neuters and all plurals, and

in all 'strong' masculines, whose inflections are as follows: nom. *dag*, dat. *daȝe*, gen. *daȝes*; pl. nom. *dagas*, dat. *dagum*, gen. *dagā*. Strong neuters differ from masculines only in taking *u* in the pl. nom., which is dropped after a long root-syllable, *scip-u*, 'ships'; *hūs*, 'houses.' The nom. sing. of strong feminines is the same as the neut. pl., *caru*, 'care'; *synn*; the oblique cases taking *-a* (*synne* = acc., dat., gen., sing.), and the pl. nom. *-a* (*synna*). 'Weak' substantives inflect with *n*; *nama*, obl. *naman*; pl. nom. *naman*, dat. *namum*, gen. *namena*. There are isolated irregularities, such as *man*, 'man'; dat. sing. and pl. nom. *menn*.

Adjectives have a twofold declension, 'strong' and 'weak.' The weak forms appear after the definite article and similar demonstratives, *gōd mann*, 'a good man'; *se gōdā mann*, 'the good man.' The definite article, which is also used as a demonstrative = 'that,' 'that one,' has nom. masc. *se*, neut. *þæt*, fem. *sēo*. The oblique cases and the plural begin with *þ*, nom. pl. *þā*. The corresponding forms of 'this' are *þes*, *þis*, *þeos*, *þis*.

The verbal forms are much simpler. The endings of a 'strong' verb, such as *bindan*, 'bind,' are as follows: indic. pres. *binde*, *bindest*, *bindeþ*; pl. *bindaþ*; pret. *band*, *bunde*, *band*; pl. *bandon*; subj. pres. *binde*, pl. *binden*; pret. *bunde*, pl. *bunden*; inf. *bindan*; gerund *tō bindenne*; partic. pres. *bindende*, pret. *gebunden*. 'Weak' verbs, such as *lufian*, 'love,' pret. *lufode*; part. pret. *gelufod*; *hieran*, *hieran*, *gehtered*; *þencan*, *pohte*, *geþoht*, 'think,' have nearly the same endings as the strong.

**Syntax.**—In its syntax O.E. has all the characteristics of an inflectional language. In the use of cases, government of prepositions, use of the subjunctive, concord, &c., O.E. grammar is very similar to that of Latin. But the distinctions of tense in the verb are very imperfect. The present does duty for the future, and the preterite for perfect and pluperfect. But we see the beginnings of periphrastic forms, such as *uile cuman*, *is cumen*, *hæfde gebunden*, although with very vague meanings. The O.E. word-order closely resembles that of Modern German, the verb being put at the end in dependent sentences: *hīc gehērdon þæt se cyning ofslagen was*, 'they heard that the king was killed.'

**MIDDLE ENGLISH.**—In the M.E. period the effects of the earlier Scandinavian conquests became visible in the form of numerous loan-words, some confined to the northern dialects, others, such as *býpe*, 'both' (Old Icelandic *báþir*), extending through all of them.

Soon after the Norman Conquest in 1066, English ceased for some centuries to be the language of literature and the higher purposes of life, and on its revival—English was introduced into the courts of law in 1362—retained only the homelier element of its original vocabulary, which was otherwise made up of French and Latin, the Latin words being generally Frenchified in pronunciation and often in spelling, even when taken directly from literary Latin. The French element itself was of various periods and dialects. Early Norman influence soon gave way to that of other dialects, especially Parisian French.

**Dialects.**—The M.E. dialects are (1) *Northern* (= the older Northumbrian), including Lowland Scotch, which still called itself 'English'; (2) *Midland* (= Mercian), subdivided into *East* and *West* Midland; (3) *Kentish*; (4) *Southern*. Although Southern answers to W.S. geographically, it is by no means its direct descendant, but shows strong marks of Mercian influence in the substitution of *ē* from W.S. *æ*, as in *dād*, &c., which is universal, and of *hieran* from *hīran*, which is very general in Southern. After the seat of government had been

removed from Winchester to London, the position of the latter on the borders of the two dialects led to a further mixture of Southern and Midland forms. Midland, being intermediate between the now mutually unintelligible Southern and Northern dialects, came to be the means of communication between them; and the history of the London dialect—which is now the history of standard English—becomes henceforth a record of increasing Midland influence. It must be noted that Northern, and, to a less extent, Midland, are ahead of Southern in their development; so much so, indeed, that 14th-century Northern is grammatically on a level with Early M.N.E.

**Spelling and Pronunciation.**—The most immediate result of the Conquest was the introduction of a French orthographic basis. O.E. *y*, *ȝ*, whose sound was preserved in Southern, was expressed by the French *u*, as in *sunne*, 'sin'; *fw*, 'fire' = O.E. *synn*, *fȝr*; *u* itself was then expressed by the French *o*, as in *comen*, 'come' = O.E. *cuman*. In Late M.E. *ū* was expressed by the Parisian *ou*, as in *houe* = O.E. *hūs*; *y* thus came to be the unmeaning variant of *i* that it now is; *a* was discarded in Late M.E., and so *ee*, *e* expressed the open as well as the closed vowel, as in *see* = O.E. *sā*; *p* and *þ* were successively discarded in favour of *w*, *th*. Voiced *f* was written *v*, as in *luven*; *c* was written *k* before *e* and *i*, as in *kīng*; *ð* was expressed by the French *ch* = *tsh*, into whose sound it passed in Late M.E., as in *child*. Strong *h* was in Late M.E. written *gh*, as in *doghter*. The difference of form between the English *z* and the French *g* was utilised by assigning *g* to the stopped sound, as in *gōd*, 'good,' *gg* to the old *cg*, as in *egge*, 'edge,' which had nearly the sound of French 'soft' *g* = *dzh*, and restricting *z* to the open sounds of *gh*, as in *dases* (later *dances*) = O.E. *dagas*, and of our consonant *y* in *zung*, in Late M.E. expressed by *y*, as in M.N.E.

**Phonology.**—The O.E. diphthongs became monophthongs in M.E.: *ea* was levelled under *e*, which in Late M.E. became *a*, so that O.E. *pæt*, *heard* became *pat*, *hard*; *dæd*, 'dead,' became *dæd*, written *deed*, *dæl* in Late M.E.; *eorpe*, *deop*, 'deep,' became *erpe*, *dep*. In Northern and East Midland *y*, *ȝ* became *i*, *ȝ*, as in *sinne*, *fȝr*, Kent. keeping *sonne*, &c. In Late M.E. *a*, *e*, *o* were generally lengthened before single consonants followed by a vowel, as in *nāme*, being kept short in monosyllables, such as *pæt*; *i* and *u* were never lengthened, as in *writen*, 'written'; *sunc*, 'son' = O.E. *gewriten*, *sunu*; *e* and *o* had already been broadened to *ē* and *ō*; so 'new-long' *e* and *g* were levelled under *ē*, as in *even*, *mete*, 'even, meat' = O.E. *efen*, *mete*. O.E. *ā* was 'rounded' into *ɔ* in Southern and Kent, and in some Midland dialects, as in *ston* (Northern *stun*) = O.E. *stān*, 'stone'; and new-long *o* was levelled under it in such words as *over* = O.E. *ofer*. O.E. *ī*, *ē*, *ā*, *ū*, *ō* were kept unchanged, as in *wīn*, *kene*, *læden* (*laden*), *hus* (*hous*), *mone* = O.E. *wīn*, 'wine'; *cēne*, 'bold'; *lædan*, 'lead'; *hūs*; *mōna*, 'moon.' Diphthongs, whose second elements were written *y*, *w* in Late M.E., developed out of the weakening of O.E. *w* and *g*. Examples are: *dai* from O.E. *deȝ*; *wei*, 'way,' from *weg*; *eye*, *ȝe*, 'eye,' from Angl. *ēge*; *dunce* through *dazes* from *dagas*; *nēwe*, 'new,' from Angl. *nēowe* (W.S. *nūwa*); *dew*, 'dew,' from *dēaw*; *bowe*, 'bow,' sb. from *boga*; *flouen*, 'flow,' from *flōwan*; *spule*, 'soul,' from *sāwol*. Other consonant changes are that of *sc* into *sh*, generally written *sch*, as in *fisch* = O.E. *fisc*; Scandinavian *sk* remaining unchanged, as in *skin*. Initial *g* became consonant *y*, as in *gard*, *zung*. O.E. *hr*, *hl*, *hn* became *r*, *l*, *n*, as in *ring* = O.E. *hring*; O.E. *hw* being generally written *wh*, as in *what* = O.E. *hwæt*.

**Inflections.**—The simplification of the O.E. inflec-

tional system in M.E. is mainly the result of phonetic changes, the most important of which are the levelling of all unaccented vowels under *e*, and of inflectional *n* under *n*, by which, for instance, the O.E. *-an*, *-en*, *-on*, *-um* were all levelled under *-en*; *n* itself was then often dropped in the Southern dialects. The striving after clearness and symmetry led to further changes. Already in Early M.E. the masc. pl. ending *-es* was extended to neuters, as in *wordes* by the side of *word*. The *-en* of weak nouns (*namen*) was restricted to the pl., the nom. sing. *name* being extended to the oblique cases of the sing. In the strong feminines the *e* of *care* was extended to O.E. *synn*, &c., making it into *sinne*, which was now invariable in the sing. like *name*, by whose analogy it then took *-en* in the pl. (*sinnen*). This paved the way for the loss of all inflections except the gen. sing. *-es* and the pl. endings *-es* and *-en*, which last unfortunately has only survived in isolated forms, such as *ocen*.

The adjective inflections were simplified in the same way, till at last there remained nothing but the distinction between *gōd man* and the pl. *gōde men*, definite *þe gōde man*, *þe gōde men*. The definite article extended its *þ* to the nom. sing. masc. and fem., which finally ran together into the indeclinable *þe*; *þat* was restricted to its demonstrative meaning, and extended to the masc. and fem. The neuter *þis* was extended in the same way. Its pl. *þis* was identified with the old pl. *þā* in its demonstrative sense, and so came to be the pl. of *þat*, a new pl., *þise*, *þese*, being formed from *þis*.

The M.E. verb retained the O.E. structure on the whole, but a large number of strong verbs assumed weak inflections. The chief changes are in the pl. pres. Southern keeps the old *-ap* (*we bindeþ*), but Midland levels it under the *-en*, *-on* of the subj. and pret. (*we binden*), and Northern changes *-ap* into *-es*, which it often drops (*bindes*, *we bind*). This last form passed first into Midland, then into Modern English.

**Syntax.**—The inevitable result of the loss of inflections was the loss of grammatical gender and concord, and the introduction of a strict and logical word-order. Prepositions had to do the work of cases, and the only remaining case, the genitive, was more and more restricted in its use. Altogether M.E. is grammatically on a level with modern Danish, which shows that there is no need to attribute its syntax to French influence.

**MODERN ENGLISH.**—In the modern period, the predominance of the London dialect is confirmed, having been further strengthened by the introduction of printing in 1477, which by degrees led to the adoption of a fixed orthography.

The main distinction between M.E. and Early Mn.E. is the loss of final *e*, which made the adjective indeclinable, and broke down the grammatical and metrical system of Chaucer's language, and made a new departure necessary. The Mn.E. vocabulary becomes even more composite than before; not only new French words, but Dutch, Italian, and Spanish, are adopted; Greek as well as Latin words are gradually popularised in vernacular prose, which, in the Early Mn.E. period, is clumsy and unidiomatic.

**Spelling.**—The dropping of final *e*, together with the shortening of double consonants—by which the M.E. distinction between *sunne*, 'sun,' and *sume*, 'son,' was done away with—led, after much confusion, to the practice of adding a final *e* to denote a long vowel, as in *wine* = M.E. *wīn*, and doubling a consonant to indicate a preceding short vowel, as in *penney* = M.E. *penē*. Through the influence of the spelling reformers, *i* and *u* were assigned to the vowel-sounds, *j* and *v* to the consonant-sounds, instead of being used at random; and *ee* and *oo* were restricted to the close M.E. sounds, as in *see*,

*moon*, the open sounds being expressed by *ea*, *oa*, *e*, *o*, as in *sea*, *stone*.

**Phonology.**—In Early Mn.E. the M.E. short vowels were kept unchanged, except that in the court pronunciation *u*, as in *man*, was fronted to its present sound; *ā* in *name* underwent the same change, the resulting *æ* being afterwards narrowed to the sound of the *e* in *there*; *i* and *ū*, as in *wine* and *house*, were diphthongised by degrees into something like the present sounds—*weɪn*, *həʊs*. Close *ē* and *ō*, as in *see* and *moon*, were moved up into the vacant places, becoming *ī* and *ū*, the open sounds in *sea* and *stone* remaining unchanged. Of the diphthongs, *ai*, as in *day*—under which *ei*, as in *they*, was often levelled—became *ai*, and then *ē*; *au*, as in *saw*, was kept, and then became a very broad long *o*, nearly as in the present pronunciation; *ou* and *ū* seem to have run together into *ou* or *ū*, as in *flow*, *soul*; *ēu*, as in *dew*, was kept; *ēu*, as in *new*, became *ju* with French *u*, and *y* in words of French origin, as in *tune*, underwent the same change: *nȳu*, *tȳn* = M.E. *newe*, *tun*.

Front *gh*, as in *night*, was kept in the earliest Mn.E., but was generally dropped with lengthening of the preceding vowel, so that *night* passed through *nūt* into *nait*. Back *gh*, as in *laugh*, was rounded into nearly the sound of *wh*, which towards the end of the Early Mn.E. period passed into *f* in many words; *l* developed an *u* before it in such words as *full* (written also *fuill*), *folk*, and was then dropped before another consonant, as in *folk*; *k* and *w* were still pronounced in such words as *know* and *write*; *r* was kept before consonants, as in *hard*.

In Late Mn.E. *a* was lengthened before certain consonants, as in *father*, *glass*. Towards the end of the 18th century, this *a* was broadened into its present sound *au*; *u*, as in *come*, was unrounded into nearly its present sound, being afterwards re-rounded into *u* after lip-consonants, as in *pull*. The vowels in *sea*, *stone*, were narrowed into close *ē*, *ō*, the former passing into *i* in the 18th century; *ju* in *new* became *iu*, whence 18th-century *jū*; *kn* passed through *nh* (voiceless *n*) into *n*; *w* was dropped before *r*, as in *write*.

The present English sound-system is characterised by its great obscuration of the vowels of unaccented syllables, most of which are reduced to *a*, as in *national* (pronounced *naʃənəl*, in Early Mn.E. *naʃənəl*), or an obscure *i*, as in *earriage* (pronounced *kʰwɪdʒ*); by its diphthongisation of nearly all long vowels, as in *neim*, *stoun* = *name*, *stone*; by its broadening of long vowels before *r*, as in *care*, *their*, compared with *came*, *they*, *r* itself being weakened to *a* when not followed by a vowel (*kea*, *hearing*), or dropped entirely, as in *further*.

The English dialects of Scotland and Ireland are no longer spoken in their purity by the educated. Scotch still preserves the pure close monophthongic vowels in *name*, *stone*. Irish keeps up the distinction between *sea* and *see*. Both, as also most of the dialects in England, preserve consonantal *r* in *hard*, &c. But on the whole, standard English pronunciation is quite as conservative as that of the dialects: compare *fall* with Scotch *fa'*. Most of the dialects in England—as also the vulgar London dialect—drop the *h*, and its preservation is mainly due to the conservative tendencies of the educated London dialect. American English often sides with the dialects against the present standard English, and is developing many peculiarities of its own. It never drops the *h*. Australian English has, of course, diverged less, and its vulgar dialect is quite 'Cockney' in character. See DIALECT, and AMERICANISMS.

**Structure of Living English.**—The characteristics of a language should always be sought in its spoken form, for the literary language is nothing but a

mixture of living and dead colloquialisms; even the most archaic literary forms, such as *thou hast*, were once colloquialisms.

Living English is essentially an *uninflectional* language, having nothing in common with such a language as Latin. It has no conception of an accusative case, of the subjunctive mood, of grammatical gender, or concord. It thus stands in a certain opposition to most of its European contemporaries.

The history of the loss of the older distinctions has been already traced. We now have to consider the processes of *re-construction* which have made English what it is—an isolating language with incipient agglutination.

The main reconstructive agent in English—besides the extended use of prepositions and auxiliaries, and a rigid word-order which we see in other modern languages—is *stress* or *accent*. One result of it is *gradation*, by which many words in common use appear in two forms, one emphatic, the other (with obscured vowel, or curtailed in some way) unemphatic, often with strong divergences in meaning and use. Such a word as *have* has, indeed, three gradations: (1) *hav* with strong stress (*you will have to do it*); (2) *hav* with weak stress (*to have it done*); (3) *hav*, *ov*, as an auxiliary (*where have you been?*). The unemphatic forms are often run together with the next word, as in *ai not*, *ai shaant* = *I will not*, *I shall not*. Stress is also used to form *attribute-groups*, as in a *good-natured man* with stress on *good*, compared with *he is good-natured* with equal stress. So also in *employer's liability for injury bill*, the strong stress on *injury* binds it with all the preceding words into one attribute-group. This enables the language to dispense with inflection and concord.

The most archaic part of English grammar is the pronouns. Here we find the last remnants of adjective-inflection and concord in the distinction between *that*, *this* and *those*, *these*. The distinction between *nom.* *I* and *acc.* *me* still survives in form, but not in spirit, for *me* appears as a *nom.* in *it is me*, and *I* is really not much more than a prefix to the verb.

The most elaborate reconstructions are those which have built up the verb with a few auxiliaries—*be*, *have*, *shall*, *will*, *do*, *go*, &c.—aided by gradation and agglutination. The future is fully expressed, with subtle distinctions in the use of *will*, *shall*, *go*, &c. There is a peculiar distinction between 'definite' and 'indefinite' tenses. Thus the definite *he is writing a letter* implies 'at the present moment,' while *he writes a letter* excludes this, implying 'every day,' 'now and then,' &c. Every tense makes a distinction between an 'unemphatic' and an 'emphatic' form (*I saw*, *I did see*; *aiw sijn*, *ai hæv sijn*), and has special forms to express *negation* (*ai sij*, *ai dount sij*), and *interrogation* (*ai sij*, *dauw ai sij*). These distinctions cross one another in various ways (thus there is a *negative interrogative emphatic* form), giving in all eight 'modes' of the English verb.

The extensive use of the gerund in *-ing*—which arose from a blending of the old partic. pres. in *-ende* with the substantive ending *-ung*, *-ing*, as in *leorning*, 'act of learning'—combining, as it does, the syntactical peculiarities of substantive and verb, gives great flexibility and conciseness to the English sentence, as in 'I remember seeing him,' 'he insisted on my staying the night.'

The comparative symmetry and simplicity of English grammar is strongly contrasted by the imperfections of its vocabulary: (1) Allied ideas are expressed by unconnected words, *sour milk*, *lactic acid*; (2) distinct ideas are expressed by the same sounds, *bear* (vb.), *bear* (animal), *bare* (adj.); (3) even where there is connection between the

words, it is disguised by stress-shifting and sound-change: *photograph*, *photography* (fotograf, fotografi); (4) the want of the power of creating new words on an English basis. These defects—aggravated by our unphonetic spelling—make the English vocabulary difficult of mastery both to uneducated natives and to foreigners.

#### SPECIMENS.

##### 1. *Old English, from the Chronicle (Early W.S.).*

378. Hēr hiene bestæl se hēre on midne winter ofer twelftan niht tō čippan-hamme; and ġeridon West-seaxna lōnd and ġesēton; and mīcel þæs folces ofer sē ādræfdon, and þæs oþres þone mæstan dæl hie ġeridon and him tō-ġeġerdon, bihton þām cyninge Ælfrede: and hē lyle werede unþeclīce æfter wudum for and on mōr-fæsten-num.

*Mercian Forms:* hine . ġesēton . ġeġerdon . unþeclīce. *Late W.S. Forms:* hyne . and . land . oþeres . hȳ, hī . ġeeyrdon . þām . unþeclīce . mōr-fæstenum.

*Translation.*—Here (at this date) him-self stole the (Danish) army at mid winter after twelfth night to Chippenhām; and rode-over West-saxons' land and settled (on it); and much of the people over (the) sea drove, and of the rest the greatest part they rode-over and to-themselves to-turned (subjected), except the king Alfred: and hs with-little troop uneasily (with hardship) throughout woods went and in moor-fastnesses.

##### 2. *Early and Late Middle English (London Dialect).*

*From the Proclamation of Henry III., 1258.*—We hoaten alle ðre trōwe in þo trōweþe þæt hēo us oȝen þæt hēo stedefæstliche healden and swæren tō healden and tō verien þō isetnesses þæt bēon imaked and bēon tō makien þurȝ þan tōforen-iseide iǣdes-men.

*Early W.S.:* hātāþ . ealle ðre trōwun . þære trōweþe þe . hie . āȝon . tō healdenns . þā ġosetnessa þe beoþ . þām tōforan-ġesetgum rādes-mōnnum.

*Translation.*—We bid all our faithful (ones) in the fidelity that they to-us owe that they steadfastly keep and swear to keep and preserve the decrees that are made and are to make (be made) through the before-said counsellors.

*From a Petition of 1388* [ð = u].—Tō the moost nȝlis and wōrthiest lōrdes, moost ryghtful and wȳsest cōn-eille, tō owre ligs lōrde the kyng cōmplaynen, if it lyke tō you, the folk of the mercerye of Lōndon as a membre of the sāmē citee of many wronges ydō tō hem.

##### 3. *Early Modern English.*

(To show the pronunciation; the vowels generally as in Italian: y = French u, o as in err.)

Mutsh gan dhei praiȝ dhe trīȝ so strai(h)t and hoi, dhe sailing poin, dhe sēlar proud and taul, dhe voin-prop elm, dhe poplar never droi, dhe bildar ȝk, sȝl king ov forests aul, dhe aspin gūd for stāvȝ, dhe soipres fȝunaral.

##### 4. *Living English (London Dialect).*

ei wans hēad on əmjʊwŋz stōri əv tuw ɪŋɡlɪʃmən, huw keim tu en in in səm əut ə dho wei pleis, an stopt dhəɔ ə fɔtnoit widhəut spɪkjɪŋ tō wənonədho. et dhi end əv dhæt taim ə frɛnʃmən kɔɪn, and in wən dei hɪj meid frɛndz widh dho tuw ɪŋɡlɪʃmən sɛprətli, and intrədʒʊnst dhom tō wənonədho.

**BIBLIOGRAPHY.**—The following list includes only those books which are directly useful, all that is antiquated and has only an historical interest being excluded. Books specially useful to beginners and those who do not wish to go deep into the subject are marked \*. Unfinished dictionaries, &c. are marked †.

*General Guides.*—J. Storm, *Englische Philologie; Anleitung zum wissenschaftlichen Studium der englischen Sprache* (Heilbronn, 1881); \* W. Victor, *Einführung in das Studium der englischen Philologie mit Rücksicht auf die Anforderungen der Praxis* (Heilbronn, 1888).

*Periodicals.*—† *Transactions of the Philological Society*, London; † *Englische Studien*, ed. by E. Kälbing (Heilbronn, since 1876); † *Anglia*, ed. by R. Wülker (Halle, since 1877).

*Old English.*—\* H. Sweet, *An Anglo-Saxon Primer*, with grammar, notes, and glossary (3d ed., Oxford,

1885); H. Sweet, *An Anglo-Saxon Reader, in Prose and Verse*, with grammar, notes, and glossary (4th ed., Oxford, 1884); H. Sweet, *A Second Anglo-Saxon Reader, Archaic and Dialectal* (Oxford, 1887); E. Sievers, *An Old-English Grammar*, translated and edited by A. S. Cook (2d ed., Boston, U.S., 1887); F. A. March, *A Comparative Grammar of the Anglo-Saxon Language* (Lond. 1870), for syntax; H. Sweet, *The Oldest English Texts*, with introductions and a glossary (Lond., Early English Text Society, 1885); C. W. M. Grein, *Bibliothek der angelsächsischen Poesie*, texts and glossary (Göttingen, 1857-64), out of print; + T. N. Toller, *An Anglo-Saxon Dictionary*, based on Professor Bosworth's collections (Oxford), untrustworthy.

*Middle English.*—\* H. Sweet, *First Middle English Primer; extracts from the Ancien Rible and Ormulum*, with grammar and glossary (Oxford, 1884); \* H. Sweet, *Second Middle English Primer; extracts from Chaucer*, with grammar and glossary (Oxford, 1886); Morris and Skeat, *Specimens of Early English*, with introduction, notes, and glossarial index (Oxford, 1886), Part I. 1150-1300; Part II. 1298-1393; W. Skeat, *Specimens of English Literature, 1394-1579*, with introduction, notes, and glossarial index (Oxford, 1886); E. Mätzner, *Allenglische Sprachproben*; vol. i. Sprachproben; + vol. ii. Wörterbuch (the best dictionary of M.E.); \* Mayhew and Skeat, *A Concise Dictionary of Middle English* (Oxford, 1888); F. H. Strattmann, *A Dictionary of the Old English Language* (3d ed., Krefeld, 1878); *Supplement* (Krefeld, 1881); B. Ten Brink, *Chaucer's Sprache und Verskunst* (Leip. 1884); E. Bienenkel, *Streifzüge durch die mittenglische Syntax unter besonderer Berücksichtigung der Sprache Chaucer's* (Münster, I. W. 1887); L. Morsbach, *Ueber den Ursprung der neuenglischen Sprache* (Heilbronn, 1888).

*Early Modern English.*—E. A. Abbott, *A Shakespearean Grammar* (Lond. 1872); A. Schmidt, *Shakespeare-Lexicon* (Berlin and Lond. 1886).

*Living English.*—\* H. Sweet, *Elementarbuch des gesprochenen Englisch* (2d ed., Oxford, 1886).

*Scandinavian.*—\* H. Sweet, *An Icelandic Primer*, with grammar, notes, and glossary (Oxford, 1886); Cleasby and Vigfusson, *Icelandic Dictionary* (1874).

*Old French.*—\* H. Suchier, *Aucassin und Nicolette, mit Paradigmen und Glossar* (Paderborn, 1878); Bartsch, *Chrestomathie de l'ancien Français* (1880).

*History of English.*—F. Koch, *Historische grammatik der englischen Sprache*, Kassel (new ed.); E. Mätzner, *Englische grammatik* (3d ed., Berlin, 1882-85), for quotations and syntax; Eng. trans. 3 vols. 1874; + J. A. H. Murray, *A new English Dictionary, founded mainly on materials collected by the Philological Society*, Oxford; C. Richardson, *A new Dictionary of the English Language* (Lond. 1844), for quotations; \* Chambers's *Etymological Dictionary of the English Language* (1889); \* C. Annandale, *A Concise English Dictionary, Literary, Scientific, Etymological, and Pronouncing* (1886); W. Skeat, *Etymological Dictionary of the English Language* (2d ed., Oxford, 1884); \* W. Skeat, *A Concise Etymological Dictionary* (2d ed., Oxford, 1885); + A. J. Ellis, *On Early English Pronunciation* (Lond.); \* H. Sweet, *A History of English Sounds from the Earliest Period*, with full word-lists (Oxford, 1888); Chambers's *Cyclopædia of English Literature*, a history of British Authors, with specimens of their writings (4th ed. 1885).

**English Literature** is, in its largest sense, the mind of the English-speaking races, expressed in successive generations by the fittest representatives of each succeeding form of thought. All conflicts of opinion through which decisive action has been reached lie, with their opposing arguments and with the passions they excited, in the books that form the literature of a people; these show for each nation, in strength and weakness, all the workings of the mind that shaped its history. Such a literature must express also the slow forward movement towards higher civilisation, coloured variously by the influences of race and climate, and brought home to us by fellow-feeling with the individualities of earnest men.

Before the English came with power into Britain there was a Celtic population of the Gael and of the Cymry, each with a literature diffused chiefly by rhythmic recitation. Many traditions of later

invention, with perhaps a few snatches of the oldest song, that passed with no great change from lip to lip of generations living in some secluded home among the hills, carry the mind back to a Gaelic literature that gathered much about Fionn, Oisín, and a battle of Gablra, said to have been fought in the year 284. In like manner we have traces of a Cymric literature, strongest in the time of battle for home and country against English invasion. Tribes of the Celts in Britain gathered their forces for a last firm stand, and were overthrown at Cattraeth; Aneurin's poem, the *Gododin*, which celebrates the chiefs who fell, tells us of this battle. To the battle of Cattraeth there has been a date assigned, the year 570. If King Arthur ever lived, he lived in that 6th century, and shared its struggle.

By the year 570 the settlements of English on our eastern and southern coasts had made sure their predominance. Various Low-German tribes from the other side of the North Sea (see ENGLAND) had been finding their way over to our eastern and southern coast for many years before the time of the six settlements which Bede described (449-547). Their original differences are still marked in our dialects, in differences of frame and feature, and even of character. In our literature the traces of such difference are at first very distinct, and they have at no time been altogether lost.

At first the strength of English literature was in the north. Little wealth had been drawn from the meadow-land among the mountains of Scandinavia. Its seas could be fished only by men strong to brave the waves of the Atlantic. Outward nature was alive with wonders that quickened imagination, and with necessities that called upon the energies of men. Wealth was only to be had by plunder, and a young Norseman counted for little among his neighbours until he had brought home his first shipload from a viking expedition. Such energy of Northmen from the shores of Sweden, Norway, Jutland, who were not particular as to the nationality of any strong man who sailed with them, first gave its stamp of vigour to the north of England. They came, not Christians, and were here first brought under the influence of Celtic monks and priests, who were devoted to their missionary work, and among whom women were fellow-workers. The Celtic people of the north, yielding to the new-comers the fertile land, kept their flocks and herds upon the hills. The two peoples were neighbours who had reason to respect each other. From time to time there would be intermarriages, and then began that gradual admixture of Celtic with Teutonic blood which has added a new vigour to the English race.

The fervour of the Celt brought to the conversion of the northern English a noble zeal and self-devotion. The abbess Hilda, who drew Cædmon into the fellowship of her monastery at Whitby, in which men and women worked together for the spreading of the gospel, was taught in the Columban school. The work of Cædmon was to spread among the people knowledge of the chief truths of religion, in what is now called a 'paraphrase,' that took the form of poems shaped for recitation by the people to each other upon festival occasions, and by the men who made it their vocation to chant tales of battle and adventure. It is a time of strength in any literature when men's minds are occupied by some great interest that touches the essentials of life. The strength of the old Greek literature was brought out when patriots fought for their homes against the power of Persia. In the beginning of our English literature, strength came from the spiritual war to extend the kingdom of Christ. Cædmon died about the year 680;

and Bede, who tells us of him, was in the year 680 a child of seven. Aldhelm, whose English songs, familiar in King Alfred's time throughout the country, are now lost, was then a young abbot of twenty-four, who had devoted his life and fortune to a work at Malmesbury like that of the abbess Hilda at Whitby. With these monasteries were associated many forms of labour for advance of civilisation, including, of course, the formation of schools. Bede in the monastery at Jarrow became the first great teacher. He shaped, in Latin, manuals for use in education, and thus his works serve as an encyclopædia of the best knowledge of his time. He gathered also, by wide inquiry, materials that were digested into the first History of England; that was his *Ecclesiastical History*, finished in 731. The history of the church in those first days was inseparable from that of the people among whom it had laboured in its missionary work.

The 8th century, to which Bede's work belongs, was the golden time of our First-English or Anglo-Saxon literature. In some monastery, perhaps not far from Whitby, a monk who found delight in the old tales of the Norseman and the Dane had shaped into the language of his country what probably had come with its Teutonic settlers as a saga of the Danes. With a few short interpolations of Christian thought, this old poem, named from its hero *Beowulf*—its writer is unknown, and it is assigned usually to more than one—reproduces all the features of life in the north before it had been touched by Christianity. Thus our English literature begins with two great poems, one heathen, the other Christian in essence. Each of these works, the greatest that remain to us in First-English, survives only in a single MS. With few exceptions the other pieces of First-English literature have as narrowly escaped total destruction. We owe our knowledge of them to the preservation of two MS. collections; one known as the Exeter Book was presented by Bishop Leofric, near the time of the Norman Conquest, to Exeter Cathedral; the other is the Vercelli Book, which was discovered in 1822 in the cathedral at Vercelli. One poet's name is preserved—Cynewulf—interwoven by himself in rimes with pieces of his verse. He wrote *Elene* and other church legends in verse of considerable merit, but his date is doubtful. Probably he lived in the 8th century. In that century of greatest energy of thought among the Anglo-Saxons, the empire of Charlemagne drew light from a York-shireman, Alcuin, who was appointed to do for its monasteries and their schools what might be called the work of a great minister of public instruction. He had been born in 735, the year in which Bede died, and it was in 782 that he took up his residence at Aix-la-Chapelle.

But when Alcuin died in the year 804, the simpler question of the establishment of Christianity had passed into the more complex forms of battle against heresies, of struggle to maintain full uniformity of theological opinion. At the same time advance of thought was being checked in England. There were continued attacks of the Northmen, some of whom were trying the mettle of King Alfred, at the same time that others were following Rollo up the Seine to lay the first foundation of the Norman power. Those who followed Rollo in 876 learned in Normandy the language of the women of the country from which their descendants afterwards crossed over to England to make conquest of a kindred people. In the 9th century John Scotus Erigena, born possibly in Ireland, possibly in Ayrshire, was an acute thinker established at the court of Charles the Bald. He wrote a Latin book *On the Division of Nature*, which, by its endeavour to bring the

teaching of theology into philosophical harmony with other teaching in the schools, yet without opposition to a single dogma, laid the foundation of what is called the Scholastic Philosophy.

King Alfred was then living, and working strenuously for the revival of lost learning. Ruin of a monastery meant in those days the annihilation of a school; and the ravages of the Danes had caused such decay of learning that in re-establishing the ruined schools Alfred translated the most important books of the schools into the language of the people. For Latin could no longer be the language through which studies were pursued. Orosius, whose *Universal History* had been a school-book, was thus translated, with omission of whatever was not practical, and with addition of new geographical detail. Bede's History was translated. A favourite school-book for ethical training had been Boethius *On the Consolation of Philosophy*. That also was translated by King Alfred. For the higher training of the clergy the king, justly named Great, turned into English Pope Gregory's book on the *Pastoral Care*; and to him also is ascribed the foundation of the continuous record of the annals of the country, known as the *Saxon Chronicle*, which now and then had afterwards an entry in verse, especially, under the year 937, a poem on the battle of Brunanburh (q.v.). The noble work of Alfred, who died in October 901, filled his kingdom of Wessex with new life, and the centre of intellectual energy was thus removed from north to south. The work of Alfred's son and grandson spread this new influence, until, in 954, the grandson, Eadred, free of the last of the under-kings, ruled over all England from the Channel to the Firth of Forth. The centre of intellectual energy was then the midland region, which included the five boroughs that had been strongholds of the Danes in Mercia. But after the death of Alfred, First-English literature passed into work associated with honest endeavour to restore religion by restoring strictness of monasticism. The chief interest of this period for us is in the *Homilies* of Ælfric, who wrote books also to aid his work of teacher in the school at Winchester. Ælfric's *Homilies* were upon the series of days kept holy by the church, and thus we have in them an exposition of the doctrines of the Church of England at the end of the 10th century. The first of the two sets in which they were arranged was written in the year 990. A poem on the battle of Maldon in the year 994 tells a victory of the Danes over Byrhtnoth, who was killed in the battle. It has much of the old spirit of the poems written, as this also was, for recitation to the people. It differs, however, from the older work in being a plain record of facts, not wanting in animation, but without the play of fancy that transforms the real into the mythical by painting some strong enemy as giant or fire-breathing dragon.

The Norman Conquest brought a royal court in which French was familiar, while Latin was the common language of the learned throughout Europe. Friends of the Conqueror held all the places of high trust, and of those who had money to spend few would pay it for written records of the English pieces still recited to the country-people. From 1066 till about the year 1200, except in a few religious writings of no great importance, English literature speaks the thoughts of Englishmen through French or Latin. The literature in the language of the people had not ceased to be; but there was nobody who cared to put it upon record. Even where it was already written, it might be rubbed from the parchment to make a palimpsest in which English was replaced by French or Latin.

Of the English literature written in Latin after

the Norman Conquest, a very large part was monastic chronicle. Every great religious house set up its chronicle, which might begin with Adam or with Hengist and Horsa, but which, wherever it began, was a compilation of no value till its record came near to the date of writing. Then it included facts yet within living memory, and became more and more valuable as a record of the past, until it became, for the occurrences of each successive year, the testimony of a living writer. From these chronicles we have our surest knowledge of the past. They were written usually by men whose sympathies were with the church and with the people, who cared little for pomp and show, but had clear notions about duty. There was strength of England in their practical simplicity. The most important of the monastic chroniclers were Ordericus Vitalis, who wrote an *Ecclesiastical History of England and Normandy*, and William of Malmesbury, who wrote a *History of English Kings*. Each closed his chronicle and probably his life about the same time, 1141-42. In William of Malmesbury the arrangement of the narrative showed a chronicler who had the genius of a historian. Milton placed him next to Bede. About the year 1147 a stream of romance broke from among the hills in the *History of British Kings*—British as distinguished from English—by an imaginative Welsh ecclesiastic, Geoffrey of Monmouth. This Latin chronicle, enriched by its author's fancy, began with the mythical origin of Britain in Brut, a great-grandson of Æneas, and went on through tales of kings, as Gorboduc and Lear, from which our poets afterwards drew subjects for their verse. These led to stories of King Arthur, who in this book came to life again, and became the hero of that cycle of romance in English literature which answers to the cycle of the Charlemagne romance in France and Italy. Geoffrey of Monmouth's Chronicle was abridged by Alfred of Beverley; it was turned into French verse by Geoffrey Gaimar and also by Wace, whose version supplanted Gaimar's and abides in literature as Wace's *Brut*. Romances of Arthur, Merlin, Lancelot, Tristan, were supplied abundantly as the demand for them increased. Walter Map was a man of genius, who was chaplain to Henry II. He attacked abuses of the church with witty Latin poems, that set forth a Bishop Goliath as type of the fleshliness in which the spiritual life of the church was being lost. Walter Map arranged the chief Arthurian tales into a sequence, and put soul into them by uniting them inseparably with the spiritual allegory of the Holy Grail. Thus, within forty years after they had first come into our literature, the tales of King Arthur were associated, as they still are, with the spiritual life of the English people.

After the year 1200 English regained its place in literature as the language of the country, and we have an increasing number of MSS. containing works by Englishmen written in English, as well as in French and Latin. To a date near 1205 is assigned an English poem of about 56,000 lines, in which the famous story told by Wace in French was told again by Layamon, a priest living near Bewdley by the Severn. Layamon's *Brut* is the first great piece of literature in Transition English, and near to it in date is a large fragment of a work named from its author, a canon of St. Austin's order, Brother Orme or Ormin, the *Ormulum*. This was a metrical arrangement of the series of gospels appointed to be read in church throughout the year, set forth in simple narrative, each of them followed by a little homily upon it, written in like manner for pleasant recitation to the people. To this period belongs also the rise of the Robin Hood and other ballads, and the telling in English verse

of metrical romances, such as those of *Havelok* and of *King Alexander*, that at first were told in French.

The foundation of the Dominicans as preaching friars for the maintenance of orthodoxy in religion, and of the Franciscans for the spread of the religious life by brotherhood with the poor, was in the beginning of the 13th century. Books being forbidden property to the Franciscans, they escaped from bondage to their records of opinion, looked straight to nature, and advanced the knowledge of the outward world. The first rector of a Franciscan house at Oxford was Robert Grosseteste, who in 1235 became Bishop of Lincoln, and made strenuous war against abuses of the Roman government of the church. He found that three times the revenue of the king of England was being paid for the support of absentee Italians, to whom the pope gave English church livings. Roger Bacon, who settled at Oxford as a Franciscan under Grosseteste, died after the year 1294, and had produced the most advanced body of scientific knowledge, the result of independent thought and experimental research, then to be found in Europe. He set it forth in his *Opus Majus*, *Opus Minus*, and *Opus Tertium*, all poured out in fifteen months to satisfy the pope's request for an account of what he knew. Robert of Gloucester's chronicle from the siege of Troy to the death of Henry III. in 1272 put English history into verse for diffusion among the people, still chiefly by recitation. In the reign of Henry III. appeared in October 1258 the first proclamation in English since the Conquest. There was not another in that reign. At the close of the 13th century the wisdom of the people was gathered also into the metrical *Proverbs of Hendyng*.

At the beginning of the 14th century the religious spirit of the people was expressed by Robert of Brunne's metrical version—as the *Handlyng Synne*—of a *Manuel des Pêchés* that had been written in French by a Yorkshirman, William of Waddington. There was in the popular poem of 'The Land of Cockaigne' a homely satire on the sensualism that had spread among the monks, who now had too much to live upon and too little to do. The miracle-plays that first came into use after the Conquest had developed greatly. Early in the 14th century long sequences of Bible story, then first set forth in the language of the people, were so dealt with by trade-guilds as to be a great means of bringing the Bible into the street, and vividly presenting to the people the events on which the forms of their religious faith were founded. Such sequences of miracle-plays have come down to us—the Chester, the Coventry, the Wakefield or Towneley, and the York. There are known to have been more than these, and they did not wholly go out of use until the reign of Elizabeth. Englishmen then had Bibles to read in their own tongue, and had learned to read them, so that there was no more need for the device of an *Ormulum* or of a sequence of miracle-plays to show what they contained.

While English literature was in such ways the voice of the nation, the genius of Dante had raised literature in Italy to its highest artistic form, the higher for close union with all that was felt to be most real in life. The year 1300 is the assumed date of the *Divina Commedia*. Dante, who died in 1321, was followed by Petrarch (born in 1304), and by Boccaccio (born in 1313). Petrarch and Boccaccio were the great living poets of Italy when Chaucer's genius was being shaped in England. They died nearly at the same time—Petrarch in 1374, Boccaccio in 1375, when Chaucer was in ripest manhood, and the better artist for the influence these great Italians had upon his work.

But energies of thought in care about essentials were the main cause of the strength of English

literature in the 14th century. There was continued provision of monastic chronicles, also of religious poems, one of them, the *Cursor Mundi*, of great length. But a new mind found utterance. Decay of spiritual life in the church, as its wealth became its weakness, and caused poets and reformers to lament 'the fatal gift of Constantine,' had given cause for earnest questionings and struggles for reform. At the university of Paris, in 1324, Marsiglio of Padua had controverted the sacerdotal limits of a church, had declared only Christ the judge of heresy, and had broken with the medieval view of papal authority. In this country William of Ockham, called the invincible doctor, argued boldly against the pope's power in temporal affairs. It was he who brought the Scholastic Philosophy to a close by reasoning upon doctrine without faith in the infallibility of dogma. The great movement of the 14th century towards reform was prompted by visible corruption. Wyclif himself as a reformer looked at first mainly to discipline, with which questions of doctrine became gradually more involved. For seventy years, from 1309 to 1378, the popes were at Avignon under French influence, and this quickened English resistance to their claims. For the next forty years or more the influence of the papacy was further weakened by the rivalry of two popes, one in France and one in Italy. Thus, while John Wyclif, who died on the last day of the year 1384, having secured between 1380 and 1382 a complete translation of the Bible into English, represented in our literature of the 14th century a strenuous reform movement within the church, William Langland, in a great poem addressed to the people at large, the *Vision of Piers Plowman*, sought to animate men to the search for Christ, and battled vigorously with church corruptions. Five great pestilences in the 14th century—the greatest the Black Death of 1348–49—were regarded as signs of divine wrath against sin, and added much to the intensity of feeling. Langland, who wrote his Christian poem, which made love 'the triacle of heaven,' between 1362 and the close of the century, seems to have been urged to utterance by the great pestilence of 1361.

The Jack Straw rebellion of 1381 caused John Gower, a wealthy gentleman, religious, liberal, and with distrust of Wyclif's followers, to seek the source of all ills of the land by a review in his Latin poem, *Vox Clamantis*, of all orders of society. In this, although an orthodox churchman warning against heresies, and one who had no sympathy with popular violence, he wrote with emphasis of the corruption of the papacy and the gross appetites of the religious orders. Gower wrote three great books, and wrote them in what still were the three languages of English literature. Of his book written in French only the name remains, *Speculum Meditantis*; that in Latin was the *Vox Clamantis*. In his English poem, the *Confessio Amantis*, Gower, like Chaucer, followed the lead of Boccaccio's *Decameron* in threading together upon a connecting narrative a series of tales. Like Chaucer's, they were told in verse. Gower's tales were moralised to illustrate the seven deadly sins, and one book dealt with a question pressed on the country by the gross misrule of Richard II., the duties of a king. Gower lived until 1408, blind during the last eight years of his life. Geoffrey Chaucer died in 1400. In the *Canterbury Tales*, with their Prologue and the rest of the connecting thread of narrative, as well as in other writings, Chaucer shows a genius akin to Shakespeare's. Not only is there a rare dramatic power manifested clearly, though there was not yet a drama, but he had also the calm sense of highest truth, and that kindly breadth

of human sympathy without which a power such as Shakespeare's cannot be. In his other poems Chaucer seems in earlier life to have been influenced by the French poets fashionable at court; but he came more and more under the influence of the great Italian masters. His *Troilus and Cressida* and his *Knight's Tale* are free versions of two of the most famous poems written by Boccaccio, and the influence of Dante was upon his later work. In the north, while Chaucer wrote, the spirit of liberty maintained by the endeavours of the kings of England to extend their sovereignty beyond the Tweed produced from John Barbour, Archdeacon of Aberdeen, his poem of the *Bruce*, which was half-finished in 1375. Barbour wrote also a collection of church legends which were printed in 1881–82.

In the earlier half of the 15th century there were many influences adverse to the maintenance of the high standard of English literature. There were civil wars and there was foreign war of aggression, part of the endeavour of the kings of England to maintain and extend sovereignty in France. None of these wars were inspiring to the men on the south side of the Tweed. Scots and French were driven to alliance against a common danger; and in battle for their independence the Scots bred the better poets. In England at the beginning of the 15th century there were, indeed, two poets of mark, John Lydgate and Thomas Hoccleve or Hoccleve, each of them about thirty years old when Chaucer died. Hoccleve was a clerk in the office of the Privy Seal, who wrote in English his chief poem *De Regimine Principum*, on the duty of kings, that it might be humbly presented to King Henry V. as a reminder to him that Hoccleve and other clerks in the government service could not get payment of their salaries. Without disloyalty Hoccleve pointed out the evil of aggressive war. John Lydgate, an accomplished monk of Bury St Edmunds, had travelled in France and Italy before he became the most famous teacher in his time of rhetoric and poetry. He drew many to the monastery school of Bury St Edmunds, and himself wrote much good verse that was in high repute. Besides many short pieces and lives of saints, he wrote especially three larger poems—one was his *Troy Book*, on the siege of Troy; another was the *Story of Thebes*, with a pleasant introduction linking it to Chaucer's *Canterbury Tales*; the third, his most important work, was the *Falls of Princes*, a version through the French verse of Laurent de Premierfait, from the Latin prose of Boccaccio's *De Casibus Illustrium Virorum*. James I. of Scotland, captured as a child, instructed in English manners as a prisoner at the English court, married to a cousin of Henry V., and crowned at Scone in 1424, was too manly to be made a puppet in the hands of England. His poem the *King's Quhair*, which celebrates his love for Jane Beaufort whom he married, is one of the best pieces written as in the school of Chaucer; and if he was also the author of a piece so homely and vigorous as *Peebles to the Play*, with its humorous scenes of life among the people, he had a master's breadth of power.

Wyclif's followers were rigorously persecuted in the earlier years of the 15th century. John Huss was burned in 1415 by the Council of Constance, three or four months before the battle of Agincourt. On Christmas-day in 1417 a noble-hearted gentleman, Sir John Oldcastle, Lord Cobham, who had befriended the Lollards, was hung by the middle from a gallows with an iron chain and roasted alive. That was one stage on the way from Wyclif to Luther. In 1449 Reginald Pecock was raised from the bishopric of St Asaph to that of Ely, and on the part of the bishops undertook an answer to the complaints made by the

Lollards against the higher clergy. The Lollards were forerunners of the men called afterwards Puritans, who wished for a church with all its rites and ordinances founded upon Scripture and freed from the traditions of men. Pecock's answer to them, called the *Repressor of over much Blaming of the Clergy*, a large work in English prose, admitted their right to be reasoned with, and gave to reason the same place that was assigned to it long afterwards by Richard Hooker, when he opposed the Puritan view at the end of Elizabeth's reign. There are, indeed, many points of resemblance between the arguments of Pecock's *Repressor* and those of Hooker's *Ecclesiastical Polity*. But Pecock, because he reasoned with the people in their own tongue, instead of compelling obedience, was condemned by his own order, and imprisoned for the rest of his life in Thorney Abbey; while Hooker for like service in a later time won honour as a champion of the church. Civil as well as religious liberty was represented even in our scanty 15th-century literature by Sir John Fortescue, Chief-justice in the reign of Henry VI. Fortescue, when his king's cause was lost and he was an exile in France with the queen and the young prince who might hereafter be king in England, gave to the prince a lesson on the limits of an English king's authority, comparing it with the absolutism of the king of France. He wrote like a sound constitutional lawyer on the *Difference between Absolute and Limited Monarchy*, and about the year 1463 *De Laudibus Legum Angliæ*. By that time new powers had begun to work in Europe for the shaping of the future. The capture of Constantinople by the Turks in May 1453 drove into exile many learned Greeks, who earned their living in Italy and elsewhere by teaching. They had a ready welcome at Florence, where Cosmo de' Medici was establishing his power. There began in this way a diffusion of Greek studies, through which Plato came to life again, and his doctrines came in strong aid of the movement against fleshly corruptions of the church. A saying that arose then, *Cave a Græcis, ne fias hæreticus*, shows the supposed tendency of these new studies. At the same time a new force, which would quicken greatly the formation of opinion in the world at large, was coming into life through the discovery of the art of printing with movable types. In 1455 the printing of a Bible with such types was finished. The working printers, presently dispersing, carried their profitable skill to other places. There was a press at Rome in 1466, at Paris in 1469, and the new art was brought into England by Caxton about 1477. The 15th century closed with another event fruitful of great consequences—the discovery of the New World (1492).

Luther and Raphael, born in the same year, 1483, were youths of eighteen in the first year of the 16th century; Michael Angelo and Ariosto were young men of twenty-six. The intellectual predominance obtained by Italy through the free life of her republics was not immediately destroyed by the establishment of petty tyrannies as single families won mastery over their fellow-citizens. The new lords, of whom Lorenzo de' Medici (who died in 1492) was a great typical example, spent freely the money of their subjects upon luxuries of art. They led the way in encouragement of every form of intellectual life that could keep active minds busy upon other questions than those which concerned their ancient rights. At the little Italian courts every gentleman was, to the best of his power, a small artist who cultivated ingenuity in clothes, in manners, and in words. When our English youth travelled, in Henry VIII.'s time, into Italy for polish, they brought home fashions of speech and writing that developed in new form an Italian influence upon our literature. This was

not, as in Chaucer's time, the influence of one great writer on another, but the diffused social influence of a prevailing fashion.

Struggle for independence had raised poets in Scotland, of whom there is a long list in William Dunbar's *Lament for the Makars*, first printed in 1508, when Andrew Millar and Walter Chepman had just set up the first press in Edinburgh. Robert Henryson, schoolmaster of Dunfermline, shrewd, homely, and religious, author of the first pastoral in our literature, *Robin and Makyn*, of a sequel to Chaucer's *Troilus and Cressida*, the *Testament of Cressid*, and of translations from Æsop's fables, was then dead. William Dunbar himself, the next great poet after Chaucer, was about forty years old when he received, in the year 1500, a pension of £10 Scots from James IV., whose marriage with Henry VII.'s daughter Margaret, in 1503, he celebrated with his poem of the *Thistle and the Rose*. It was probably in 1501 that Gavin Douglas dedicated to James IV. his poem of the *Palace of Honour*. In July 1513, two months before the disaster at Flodden, Gavin Douglas finished the earliest translation of the *Æneid* in our literature, with verses of his own to introduce each book. Gavin Douglas, become Bishop of Dunkeld, died of the plague in 1522, a pensioner at Henry VIII.'s court. Dunbar was dead in 1530. David Lyndsay, who became Sir David Lyndsay of the Mount, was associated with James V. of Scotland from his infancy, and addressed to him many admonitions on the sorrows of the people and the duty of a king. Lyndsay's *Satire of the Three Estates* was the most important example in our literature of the Morality Play that expressed moral teaching by the dramatic action of personified attributes and forms of life. It shadowed forth the reform wanted in the Church of Scotland; and the passing by the Estates in 1540 of what was called a friendly act of reformation was prepared for by the public acting of this satire in the presence of the king. Lyndsay's last poem, the *Monarchie*, was finished in 1553, and in this 'the Scottish poet of the Reformation,' as he has been called, becomes distinctly Lutheran. The vigour of these poets of the north was not equalled in the south under Henry VII., where Stephen Hawes, a gentleman of the king's chamber, wrote, among other poems, a *Pastime of Pleasure*, with an allegory of the course of life in knightly adventures, that show distinctly, but in form only, the advance of allegorical literature towards its crowning work in Spenser's *Faerie Queene*. John Skelton, who had been chosen for his scholarship to be a tutor to Henry VII.'s children, wrote in the reign of Henry VIII. satires against church corruption, in little torrents of short lines with continuities of rhyme, verse called Skeltonical. It poured out the complaints of *Colin Clout*, who represented the poor Englishman of country and of town, and it boldly attacked Wolsey himself in the height of his power. From Skelton, with whom he had fellow-feeling, Spenser borrowed afterwards for himself the name of Colin Clout.

Greek scholarship was still advancing, and was still associated with the free advance of thought. William Grocyne, having learned Greek in Italy, first taught it at Oxford in 1491. The physician, Thomas Linacre, who had also learned Greek in Italy, taught also at Oxford. In 1497, when Erasmus sought to learn Greek, he came from Paris to Oxford for it. John Colet, the founder of St Paul's School in 1510, and William Lily, its first headmaster, were Oxford scholars, associating their Greek studies with ideals of true life and a wise liberality of thought. Thomas More when at Oxford was inspired by these men, and his *Utopia* (Latin, 1516; Eng. trans. 1556) imagines a commonwealth in the New World lately discovered, and through playful wit brings thought

inspired by Plato and by Plutarch into the Christian ideal of a higher policy than statecraft yet had known. More sought also to bring home the teaching of the Gospels by a Latin paraphrase. Translation of the Scriptures into the language of the people had many learned advocates who were restrained only by fear of mistranslations that would, as they thought, corrupt the Word of God.

Luther's translation of the New Testament into German appeared in 1522. Tyndale's translation into English followed in 1525. Sir Thomas More was its adverse critic, because he found Lutheran bias in the choice of words. In 1530 Tyndale finished printing his translation of the Pentateuch, made with Miles Coverdale's help. In October 1536 Tyndale was strangled and burnt near Brussels. In the same year Coverdale's completed translation of the Bible was admitted into England, and work towards the production of a translation that would satisfy all judgments was continued (see BIBLE).

From Italy there flowed new streams of literature. The *Arcadia* of Sannazaro, finished in 1504, was in a form of pastoral that spread to other lands. The first eclogue of mark in France was Clement Marot's *Complaint on the Death of Louise of Savoy*, mother of Francis I., written in 1531, and paraphrased afterwards by Spenser in the eleventh eclogue of the *Shepherd's Calendar*. George of Montemayor, a Portuguese, produced in 1542 a *Diurna Enumeratio*, which joined force with the *Arcadia* of Sannazaro as an influence on English literature. Blended with influences from the Spanish romance of chivalry, it led to Sir Philip Sidney's romance of *Arcadia*, first published in 1590, after Sidney's death. Of the same parentage came also a long line of French romances, which continued far into the 17th century.

The modern drama, based upon the form of Latin plays then usually acted, had its rise in Italy. Ariosto first wrote comedies about the year 1498; his earliest, *I Suppositi*, was based on the *Eunuch* of Terence, and the *Captives* of Plautus. Trissino's *Sofonisba*, dedicated to Leo X. in 1513, and first printed in 1529, was the first Italian tragedy of mark. The Italian sonnet was first imitated in Henry VIII.'s reign by Sir Thomas Wyatt and the Earl of Surrey. Experiments in unrhymed verse by the Italian poets led to the first use of blank verse in English literature, when the Earl of Surrey used it in translating two books of the *Æneid*, which had been so turned into Italian.

The great question of church reform became more passionate, and divided all Europe into two camps, which came to have their headquarters, one at Madrid, the other in London. Luther had died in 1546, when Calvin's age was thirty-three, and Calvin died at Geneva in 1564. Hugh Latimer preached before King Edward, and was burnt by Mary. John Knox, indignant against three ruling Maries, sounded from Geneva his *First Blast of the Trumpet against the Monstrous Regiment of Women*, just before the accession of Elizabeth. He could not make his peace with her, but, warned from England, he landed at Leith, and stirred Scotland to the heart with religious zeal. It had its aims in accord with the teaching of Geneva, but was associated by Knox with a masterly reshaping of provisions for the education of the people.

In Elizabeth's reign the struggle for all that they most prized, against Spain enriched by the wealth of the New World, lifted the hearts of men as the hearts of the old Greeks were lifted when they fought for freedom against Persia. Fashions and follies there were then as now, chiefly brought in from Italy, with an exuberance of ingenuity that touched alike the clothing of men's bodies and men's thoughts. Thus the Italian influence, which became dominant over outward forms, introduced

that straining for conceits and dainty turns of speech, alliteration, and antithesis, which was so common as to need a name. It was called Euphuism from *Euphuus*, the hero of a book by John Lyly, published in 1579, and written in the fashionable manner. Lyly wrote in that manner to win hearing. His aim was to advance a view of the need and nature of true education, which had been urged by one of the best scholars of the day, Roger Ascham, in his *Schoolmaster*, first published in 1570, two years after its author's death.

In the twenty-one years of Elizabeth's reign before 1579 English energies were growing. In that year Edmund Spenser, aged about twenty-six, produced his first book, the *Shepherd's Calendar*, following Clement Marot in his way of applying pastoral images to the religious conflicts of the time, and boldly taking his place beside the disgraced Archbishop Grindal, with whose firmness in encouraging free search for Scripture truth the poet was in sympathy. In the same book Spenser paid homage to Tityrus (Chaucer) as his master. He took the style of Chaucer for his model, avoiding the false emphasis laid on tricks of thought and phrase. Spenser was Chaucer's successor, Milton's predecessor. In the great fragment of his *Faerie Queene*, which represents man through all his powers for good striving heavenward, and attaining only by the intervention of the grace of God—of which Prince Arthur is the bearer—all militant forces of his time have their expression. The *Faerie Queene* is throughout an intense utterance of the spiritual life of England under Elizabeth, in all that were then the forms of the long battle towards a higher life for man. England was full of song. Men felt proudly the rising vigour of their country. A tailor (John Stow) was inspired to write its annals. An attorney (William Warner) wrote in verse of *Albion's England*. The defeat of the Spanish Armada in 1588 removed the common danger that had knitted Englishmen together. In 1589 the Marprelate tracts against the bishops, and the replies to them, brought oppositions of opinion in the English Church into that bitter conflict of which Francis Bacon, then twenty-eight years old, pointed out the unseemliness in a paper addressed to the government on *Controversies in the Church of England*. Shakespeare's age was then twenty-five. He had come to London probably when twenty-two, two years before the defeat of the Spanish Armada, and at that time the English drama was but twenty-five years old.

The first English comedy, *Edolph Boister Doister*, a version of the *Miles Gloriosus* of Plautus, had been written between 1534 and 1541 to be acted by Eton boys. It was a schoolmaster's chance substitution of English for Latin in a play written by him for his boys; and it was acted under conditions that would not prompt imitation. Its production, therefore, was an isolated fact. But the first tragedy, *Gorboduc*, by Thomas Sackville and Thomas Norton, acted in the Inner Temple at Christmas, 1560—actually on the first of January 1561—was a substitution of English for Latin in an English play written in the manner of Seneca, that drew to itself the attention of many young men who could write. Its grave dwelling upon the need of union to keep a people strong, a truth of deep significance to England at that time, pleased Elizabeth. The play was acted again before her, by command. It set an example that was followed at court, where English plays came into request. It showed also to young wits how they might furnish themselves with money by writing English plays to be acted by those gentlemen's servants who already had formed little companies for playing *Interludes*. Such interludes, short entertainments in dialogue by a few servants of the house, who used their skill in

ministry for the amusement of their lord and his guests, produced a form of literature in which John Heywood excelled. But these short pieces had no developed plots. Desire grew towards the new way of showing tales in action. It was an improvement on the most dramatic recitation by a single story-teller. But in the twenty-five years from 1561 to 1586 few plays of high mark were produced. There was little more than a wide spreading of the taste for the new kind of entertainment, and a development of companies of actors. At length a civic opposition drove the actors privileged to play in London out of rooms and inn-yards in the city into buildings of their own, just outside the jurisdiction of the mayor and corporation, which they erected for sole use as theatres. These first theatres were built in 1576. Ten years afterwards Shakespeare came to London when the new conditions of the stage had made the way ready for plays of higher mark. John Lyly had produced court plays chiefly mythological. George Peele had already pleased the queen with his *Arraignment of Paris*. Christopher Marlowe began with *Tamburlaine* upon the public stage in 1586 or 1587, his short and brilliant career ending in 1593. Robert Greene, who died in 1592, Thomas Lodge, Thomas Kyd, and others maintained a poetical drama during the six, or about six, years of what may be called Shakespeare's apprenticeship. During these years he made himself generally useful, acted, and sometimes turned old plays into new. At the end of the six years this group of dramatists, the pure Elizabethan, passed away; and for the next six years, 1592 to 1598, in which Shakespeare was master, writing plays of his own, he seems to have had no strong competitors. But in or about the year 1598 many young dramatists—Ben Jonson, Dekker, Marston, Heywood, Middleton—who were to earn fame in the next reign began to write, while Shakespeare went on with his work, remaining foremost of all. Beaumont and Fletcher, Massinger, and Ford did not write any plays until after the death of Elizabeth. Webster wrote his two finest plays in the reign of James I., and emphasised, like others in his time, that element of terror in the drama which Aristotle had joined to pity. Webster lived into the middle of the 17th century. James Shirley, who was only nine years old when Elizabeth died, and who wrote plays chiefly in the reign of Charles I., lived until 1666, the last of those who are usually called Elizabethan dramatists. The period of highest achievement in our English poetical drama falls, then, within the first ten or twelve years of the reign of James I. But already in this best time of fruition there are conditions of decay, which make it hard to say where ripening ends and rotting begins. The energies of struggle had developed a dramatic literature in Spain as in England. Influence of the Spanish drama, coinciding with a lower social tone in James's court, caused many of the plays of younger dramatists to find in intrigues of animal love the sole groundwork of invention. On the stage of Elizabeth's time there was no such restriction, but interest was shown in all the trials of the life of man.

The 17th century, from the accession of James I. in 1603 to the Revolution of 1689, was occupied by new forms of struggle about the limit of authority. Becket's struggle with Henry II. had been for sovereignty of the church over the king. From that time onward, Reformation movements chiefly were for war against the pope's claim of dominion. While England was in contest against Spain, Elizabeth was leader of her people. When removal of the danger from abroad gave freedom for domestic difference, the queen became unpopular. There was dread that civil war would come again after

her death. The two chief heroic poems at the close of her reign, Drayton's *Barons' Wars* and Daniel's *Civil Wars of York and Lancaster*, were designed—as other poems and plays were then designed—to press on Englishmen a feeling of the ills that follow when this house is raised against this house. When James I. sought less wisely than Elizabeth to maintain and magnify the power of the sovereign, he soon made the question of the limit of authority political as well as religious, and prepared the way for civil war in the next reign.

Revolt against authority of mere tradition in the teaching of the schools had its chief leader in Francis Bacon, whose analytical mind looked in his *Essays* upon the nature of man himself, and in his philosophy upon the nature of the world without him. His two books of the *Advancement of Learning*, with which he began to lay foundations for his *New Organon*, were published in 1605, and his work as teacher of the right way of experimental search into nature, unimpeded by tradition, was suggested by a strong reaction against bondage to common opinion (the Idol of the Forum) or the teaching of great men who have played large parts on the stage of life (the Idols of the Theatre). Men with a bent for science began to inquire as Bacon counselled that they should, and grew in desire towards unbiased inquiry by well-planned experiments. They were searchers into nature so inspired who were incorporated in London as a Royal Society in 1662.

But James I., though Bacon's patron, knew little of the whole advance of free inquiry that Bacon represented only in one form of study. To obtain freedom of worship, English Puritans sailed for New England in the *Mayflower* in 1620, and added strength to the foundations of an England on the other side of the Atlantic, which had its origin in the vigour of Elizabethan navigators. Part of the region that Sir Walter Raleigh named Virginia, after the virgin queen, was granted by James I. in April 1606 to a London company, whose first settlers called their town Jamestown, in honour of the king, and who produced in Captain John Smith the author of a *True Relation of Virginia*, published in London at the close of the year 1608. This may be regarded as the first book in the English literature of America. The settlers in New England who had left Old England for conscience' sake, and who included many graduates, of Oxford and especially of Cambridge, brought a new strength to the New English world that is well represented in the record of the Mather family.

John Milton went to Cambridge in the year (1625) when Charles I. became king. He joined fine scholarship and the poet's temperament to strenuous endeavour towards freedom of thought. His high ideals were expressed with the power of a master poet who had subjected his mind to long and patient training. His earlier verse was pastoral, as he thought suited to a time of preparation for a higher flight; but the period of his prose works intervened between his earlier verse and this later in which he rose to the epic with *Paradise Lost*, published in 1667. His other epic, *Paradise Regained*, was published in 1671 with *Samson Agonistes*, his one drama, modelled on the Greek. In the controversies of the day about religion, Milton was the best representative of the first principle of the Independents. They would unite all men as fellow-Christians who built their faith upon the Bible, and would leave to each the right of joining himself to an independent congregation of the worshippers with whom he best agreed in his interpretation of the Bible. Richard Baxter was the ideal type of the Presbyterian who thought

the Episcopal Church less scriptural than a church managed by presbyters and elders, but was as desirous as the ruling church to bring all Englishmen into accord with one church discipline and one form of belief. Of the church established by Elizabeth as *via media* between Rome and Geneva, the church of which Richard Hooker in his *Ecclesiastical Polity* had, at the end of Elizabeth's reign, best maintained the cause, Jeremy Taylor was in Stuart days the ablest supporter. God made us to differ that by wrestle of opinion we may win the victory for truth. Richard Hooker, Jeremy Taylor, Richard Baxter, and John Milton—who shall say which was the better Christian?

Milton's early poems were written at a time when the English drama seemed to break in its fall into a rainbow-tinted spray of song; Herrick, born lyricist, Wither, Suckling, Cartwright, Ilabington, Randolph, Cleveland, Lovelace, Cowley, Crashaw, George Herbert, and Henry Vaughan represent the graces and the follies and the grossnesses of life, the strife of parties, and the highest aspirations towards the divine ideal. Milton's *Comus*, the most beautiful example of the masque, which before Milton had been best developed by Ben Jonson, was an indirect plea for the high use of the poet's art, when Prynne had just expressed the Puritan antipathy to plays, masques, dances, in his *Histriomastix*. *Comus*, acted at Ludlow in 1634, was also a setting forth of the beauty of temperance and purity, at a time when the course of fashion, aided by the readiness of the king's friends to shew that they were no Puritans, was bringing sensuality into repute. Dr Thomas Browne of Norwich—not Sir Thomas till the time of Charles II.—in his *Religio Medici*, published in 1642, joined faith in doctrines of the church with a free, reverent spirit of inquiry. Every page of that book was rich with subtle utterance of independent thought. Milton's prose pamphlet *Areopagitica* in 1644 enshrined in a piece written carefully after the manner of a Greek oration the cardinal principle that for the advance of truth there is no safeguard to be relied upon but free exchange of thought. 'Let truth and falsehood grapple,' Milton said; 'who ever knew truth put to the worse in a free and open encounter? Her confuting is the best and surest suppressing.'

This is the battle that runs through the history of English literature. All the prose writings of Milton in the Commonwealth time dealt essentially with the question of the limit of authority; they sought the best solution of the problem between king and people that had stirred up civil war. The Commonwealth was an experiment that failed. The Restoration was a going back to a new starting-point, and trying again for an answer to the problem. It was found at last in 1688. The argument for absolute authority had its best expression in the political philosophy of Thomas Hobbes, whose *Leviathan* appeared in 1651 as his contribution to the great controversy of the time. James Harrington's *Oceana* in 1656, and Richard Baxter's *Holy Commonwealth*, show the energies at work which have made English literature at all times a true and full expression of the people's life. They were in George Wither's verse and Andrew Marvell's satire; in Butler's *Hudibras* with a wide reach of wisdom in its wit that struck at everything insincere; in *Paradise Lost*, that shapes an epic to maintain God's love against the discord of disputes about predestination and free-will; in *Paradise Regained*, with its calm burden of Rest in the Lord, enforcing faith and patience in the darkest times—dark even as the times seemed to religious men who looked at the court and country in 1671—and in *Samson Agonistes*, which was added as a scriptural example of such faith. In all work of the

best writers there was the best life of the time

appealed, still strong throughout the body of the people. The masterpiece of John Dryden, *Absalom and Achitophel* in 1681, and the poems that next followed, dealt altogether with those vital questions of the day which pointed to the coming revolution.

Strain for ingenious conceits had been an Italian fashion that spread to Spain and to France as well as to England. In all three countries it became laboured, and took the form called by Samuel Johnson 'metaphysical,' in the poetry of which John Donne in the reign of James I. was the favourite writer. At the same time Marino in Italy and Gongora in Spain illustrated the same form of decay. Our days of Enthusiasm were represented in Spain by the school of the 'Conceptistas,' and those whom we may call our later Enthusiasts were represented by the school of 'Cultos.' In France reaction against this laboured extravagance had begun in the days when English royalists of the time of Charles I. were in political adversity and lived in Paris. They who afterwards in England were patrons of literature attended the *salons* of the Marquise de Rambouillet, and were in contact with the critics and the poets who prepared the way for the predominance of France. Boileau, the master critic of this school, began his satires about the time of the Restoration, and summed up his views in his *Art Poétique* in 1673. A taste for criticism now spread; even the small wits prided themselves on sense. Boileau lived until 1711. Critics who followed his teaching in the letter rather than the spirit swarmed about him and survived him. The period of Latin-English thus came in, when writers, to avoid the low association of ideas with homely words, sought their vocabulary from the Latin side of the language, and wrote sentences that they would never speak.

Boileau opposed the strain of writers for extravagant conceits—which he called the paste brilliants of Italy—by fixing attention on the simplicity that graced the highest art in Roman literature of the time of Augustus. Works of Virgil and Horace were the models through which he would have nature to be studied. This was right counsel, but many misapplied it. In England they grew blind to the art of their own best writers who were not in obvious relation with the new French school. Deaf to the music of Chaucer and Spenser, they supposed that Waller, whose earliest verse was written in the reign of Charles I., and who died, aged eighty-two, in 1687, had been the first in England who wrote smooth verses and invented the right use of rhyme. Sir John Denham's poem on the view from *Cooper's Hill*, first published in 1643, was exaggerated into epic dignity. Dryden described it as a work that, 'for the majesty of the style, is and ever will be the exact standard of good writing.' Dryden was then advocating the disuse of blank verse in our plays, and he used for a few years the rhymed couplets preferred in France which found their way into the heroic play of the Restoration. These heroic plays, of which the first had been Davonant's *Siege of Rhodes*, were sustained in popularity by Dryden himself with plays like his *Tyrannic Love* in 1669, and *Conquest of Granada* in 1670. They retained much of the extravagance against which, on behalf of good sense, Boileau made elsewhere successful war; and the *Ichneumon*, by the Duke of Buckingham, produced in 1671, was a burlesque meant as a plea for good sense even in the theatre. The heroic plays passed into rhetorical tragedy, of which only two pieces by Otway, *Venice Preserved* and the *Orphan*, avoiding royal heroes, were distinguished by domestic

pathos. But Charles II. left Otway to starve. The rhetorical tragedies became associated with an artificial stage delivery until the time of Garrick, who went straight to nature. In the comedy of the Restoration, Sir George Etherege's profligate young gentlemen, who call themselves men of sense and have no reason in their lives, reproduce with a light touch, a grace of gracelessness, the fashionable manners of the time. But Molière, greater than Plautus or than Terence, had raised comedy in Paris to an intellectual supremacy that was felt by the best comic dramatists in England. Wycherley, whose four comedies were produced in the reign of Charles II.; Congreve, whose plays were all written under William III.; Sir John Vanbrugh, and Farquhar, who wrote also in the reign of Anne, learned from Molière to put a larger life into their art as dramatists, and produce what has been entitled the Prose Comedy of English Manners.

Until nearly the end of the 18th century this French influence prevailed. It was maintained by the just predominance of French literature, which had reached its Augustan age; but this influence, like that of Italy, had in its strength an element of weakness that increased with years. In due time it was shaken off by one more great reaction, out of which came the forms of literature in the present day.

The 18th century in English literature shows especially the course of thought between the English Revolution of 1688, of which John Locke expressed the true ideal, and the French Revolution of 1789, that sought to establish an ideal of true citizenship. It failed, but showed the way to a success much slower of attainment, towards which the English literature of the 19th century labours in every generation with more conscious resolve. The 18th century was not an age, as Carlyle once called it, 'of shams and windy sentimentalities.' There were plenty of these; but the spirit of the century lies really in the great reaction against them. Corruptions in that section of society which usually calls itself the World, that touched religion to the quick, and put formal conventions in the place of truth, had stirred resentment. Pierre Bayle, in his *Dictionnaire Historique*, implied in all his pictures of the lives of men a world without a God. A scepticism of earnest, honest minds grew up, that denied God because it could see no truth in his priests. The corruption of society, greater even in France than in England, great in both countries through the evil lives of men whose high social position made them leaders of the weak, made vice appear to be the sand upon which civilisation had been built. Mandeville's *Fable of the Bees* began, even in Queen Anne's time, the satirical expression of this doctrine, which had its highest expression afterwards in France, through the writings of Rousseau. First there was this growing conviction of wrong; then followed in France the passionate desire for remedy.

There arose in Queen Anne's reign, from the genius of Daniel Defoe, the real beginnings of the modern newspaper and of the periodical essay. Newsletters, intended to give information to one side or other in the time of civil war, had already been published before the Commonwealth. After the Restoration, Sir Roger L'Estrange, having obtained for himself the 'sole privilege of printing and publishing all narratives, advertisements, mercuries, intelligencers, diurnals, and other books of public intelligence,' produced in August 1663 the first number of his *Public Intelligencer*. When the plague drove the court to Oxford, he produced, in November 1663, the first number of his *Oxford Gazette*, which became, when the court returned to London, the *London Gazette*, on the 5th of

February 1666 (see *GAZETTE*). Other newspapers arose, which expressed opinion indirectly by representing facts in the form most agreeable to their subscribers. Daniel Defoe, having been sent to Newgate in 1703 for an ironical pamphlet against passionate attacks on the Dissenters, began, as a political prisoner, his journal, the *Review*, of which the first number appeared on the 19th of February 1704, and which appeared in and after 1705 three times a week until June 1713. This paper had two features which were new, and upon these the growing power of English journalism has since been based. Defoe aimed at exact truth, palatable or unpalatable, in his record of facts; and he joined to his record independent comment. Thus he became the founder of what is now known as 'the leading article.' He also added to his *Review* a monthly supplement that dealt wholesomely with follies and fashions of society. The notion of this was developed afterwards by Richard Steele when he established the *Tatler* in April 1709. Out of the *Tatler* came Steele and Addison's *Spectator*, which began on the 1st of March 1711, and opened the way to many later efforts of the same kind to better and refine the ways of men.

In the foundation also of the modern novel of real life, which displaced the French romances of Gomberville, Calprenède, and Madeleine de Scudéri, themselves due, as we have seen, to Spanish romances and Italian pastorals, Defoe led the way with his *Robinson Crusoe* in 1719. This did not profess to be a novel, but was, like all following novels of Defoe, written in imitation of some other form of literature that had for its chief features a true record of experience of life. Defoe's picture of a single man battling against circumstance, unflagging in the energetic use of his own resources, with unfailing trust in God, expressed so completely the new interest in the development of man, that Rousseau afterwards, in his *Emile*, made *Robinson Crusoe* the first book to be put into the hands of the ideal pupil. As the movement towards larger assertion of individual and national life advanced in Germany, imitations of *Robinson Crusoe* were so many as to form a group in literature that became known as the *Robinsonaden*.

Pope, under Queen Anne, followed the critical fashion of the time, and made his mark first in 1711, with an *Essay on Criticism*, which was writing about writing about writing. His *Rape of the Lock*, in 1712-14, was, perhaps, the daintiest trifle ever written; but it was half-earnest play upon the idleness of fashion. Under George I. Pope earned money by translating Homer. But under George II. he had grown with the growth of his time, and to the full extent of his powers he dealt in his *Essay on Man*, his *Satires* and *Epistles*, with the deeper questions of life, and felt 'with the world about him that 'the proper study of mankind is man.' From the beginning of the reign of George II. our best literature expressed the growing interest in questions of the nature and the prospects of society. Swift, under Queen Anne, had followed the critical fashion of the time with his *Battle of the Books*, but joined to it the keen use of his wit in dealing with the dissensions about religion. That was in his *Tale of a Tub*. His other writings in Queen Anne's reign belonged almost without exception to those controversies of the day that shaped the course of history, and to the labour to let light into the lives of men. Under George I. Swift was Dean of St Patrick's, deep in politics of Ireland. At the end of that reign his *Gulliver's Travels*, in 1726, expressed the meanness to which life and its aims had sunk, not more contemptuously than Gay's *Beggar's Opera* in 1728, and its sequel *Polly*, which placed pirates a little above, savages

high above, the pollutions of a civilised society. In 1723 and 1726 Allan Ramsay's *Gentle Shepherd*, Thomson's *Winter*, and Dyer's *Grongar Hill* sent a healthy breath into our literature, the first sign of a renewed sense of the beauty of outward nature. Thomson completed his *Seasons* in 1730, showing, with distinct reference to the scepticism of the time, in the world that surrounds us, God, 'parent of good.' Pope sought in his *Essay on Man*, in 1732-38, to reason against those who believed that man and nature replied 'No' to the question, 'Is there a just God?' Butler's *Analogy* was published in 1736—a triumphant effort of sheer reasoning against the same creed of despair.

The same controlling force was upon all forms of life. It touched alike the pulpit and the stage. Garrick's triumph as an actor was a triumph of natural over conventional expression. 'If this young fellow is right, we are all in the wrong,' said the old actor Quin. Even as late as 1768 and 1772, when Goldsmith's first comedies, the *Good-natured Man* and *She Stoops to Conquer*, were produced, conventional notions of dignity and traditions of false sentiment caused alarm in the breasts of managers. Sheridan's *Rivals* in 1775, and *School for Scandal* in 1777, completed the emancipation of good wit from trammels of an artificial style. Gray's poems, first collected in 1768, three years before his death, foreshadowed, with almost too exquisite art, something of the new in the forms of the old.

Good Samuel Richardson was with his time more fully than he knew when in his first novel, *Pamela*, in 1740, he asked his readers to care for the sorrows of a maid-servant. Henry Fielding in his novels painted life full of the spirit of the coming change. Byron afterwards described him as 'the prose Homer of human nature.' Fielding's *Tom Jones*, published in 1749, is a great landmark on the way from the English Revolution of 1688 to the French Revolution of 1789. Nature reasserts herself in the fresh liveliness of Smollett's novels, the last of them published in the year of his death, 1771. Fanny Burney's *Evelina* and *Cecilia* followed in 1778 and 1782; without breaking from the conventional, long-winded style, they were unconventional in substance. There was quick, fresh observation, with a grace of wit in their invention and character-painting. They were followed at the beginning of the 19th century by the works of Maria Edgeworth and Jane Austen. These two women were foremost in this way of literature, until they were left behind by the superior genius of George Eliot.

Samuel Johnson died in 1784, after forty-seven years of life in London. In 1738, after his first year's struggle with poverty as a Grub Street author, he had published his *London*, a paraphrase of Juvenal's third satire. He won his way as a man of letters, never rich, but always firm to his own sense of right, delighting in the society of men, strong in wit combats, deeply religious, but dependent only upon God. By his character he first gave its right dignity to the position of the professional man of letters. His toast to the next insurrection of the blacks, and his interest in the negro Francis Barber, whom he took as a servant, educated and treated as a friend, in visible protest against the valuing of man by the colour of his skin, may stand among many evidences of Johnson's part in the new sense of the fellowship of man. His *Rambler*, in 1750-52, following the *Spectator* in its aim, reduced to system the critical theory of the time, that sought for dignity on the Latin side of English. But Johnson lived with his time and led his time, and the style of his *Lives of the Poets*, written in 1779-81, is not that of the *Rambler*. When in 1764, Goldsmith in his *Traveller*, which, according to its second title, was a 'Prospect of Society,'

expressed the spirit of the time in mournful review of the nations of Europe, it was his friend Johnson who added those last lines that spoke the language of the 19th century, by showing that the solution of the great problems of life lies for each man within himself. Goldsmith's *Deserted Village*, in 1770, expanded a passage in the *Traveller* into a picture of depopulation caused by greed of wealth, and yet more strongly expressed the new sense of social inequalities. It also combined a charm of simplicity with what was really dignified and graceful in the old style that was giving way before impatience of formalism. The *Vicar of Wakefield*, in 1766, in substance and in manner a poet's novel, expressed even more completely the advance of time. The transition from rhetorical forms to a style founded directly upon nature is well marked in Goldsmith and in Cowper. They are on the way to Wordsworth. A strong spirit of freedom was in them. In her old age, the daughter of his friend Lord Clave described Goldsmith, whom she had known in her youth, as 'a strong republican in principle, who would have been a very dangerous writer if he had lived to the times of the French Revolution.'

In other forms of literature there was a corresponding movement. David Hume, whose philosophy raised honest questions which put more clearly and forcibly the doubts that startled a faith based only upon traditional opinion, completed his *History of England* in 1761. Begun as a history of the Stuart times before the English Revolution, it became the first work in which the whole course of English history was told with an intellectual sense of sequence in the affairs of men. The first volume of Edward Gibbon's *Decline and Fall of the Roman Empire* appeared in 1776, the year of the death of David Hume. The last volume was published in 1788, the year before the fall of the Bastille. The book was suggested by the sight of Rome in ruin. Its design was, in days when modern states seemed tottering, to draw from Rome a study of the causes of decay. The scepticism of the 18th century was in Gibbon the more strongly marked by an elaborated pomp of words that contrasts with the philosophic calm and simplicity of David Hume. The year of the first volume of Gibbon's great work was the year also of the publication of Adam Smith's *Wealth of Nations*, grown to an arch formed by a series of studies on the nature of society and on the grounds of its well-being, that had its spring in the days of Charles II. from Sir William Petty, and passed through Locke's second *Essay on Civil Government* to Adam Smith. The first volume of Blackstone's *Commentaries on the Laws of England* appeared in 1764, and Jeremy Bentham began his career as a political economist with *A Fragment on Government, being a critique on Blackstone's Commentaries*, published in the same year as the *Wealth of Nations* (1776), the year in which Malthus was born. Thenceforward the study was continuous, and passed on to John Stuart Mill and to the writers living in our day.

The year of the publication of the *Wealth of Nations* was the year also of the Declaration of Independence on the 4th of July by the English American colonies, which on the following 9th of September were first termed by congress the United States. When the political action of this country made such an issue likely, the eloquence of Burke was spent in the endeavour to avert the revolution. The colonists would not bear taxation for imperial purposes without representation. The English government maintained the right to tax. 'Assert the right,' said Burke, 'but do not use it.' That was, in brief, the policy of the Rockingham administration, inspired by Burke, and in association with which Burke began to devote his mind to the great

questions that touched the destiny of nations. The American Declaration of Independence gave to the world another England in the New World as an independent civilising power. It was one result in the long process of evolution that has quickened the development of the whole race of man. If Burke, who seemed to be a friend to the Americans, was a bitter opponent of the French, it was because his Conservative mind, Liberal in its tendencies, sought to avert in one case the revolution that he dreaded, and sought in the other case to suppress a revolution that had broken out, and might possibly involve a struggle to secure great change by violence in his own country.

The thin volume, published at Kilmarnock in 1786, revealed to the world in Robert Burns a lyrical poet and satirist of the first order, who found time later, amid the troubles of a short and stormy life, to fashion from his heart such love songs as the world has never seen. William Cowper in his *Task* (published in 1784) said of the towers of the Bastille that there was not an English heart that would not leap to hear that they were fallen. When they fell hearts of young poets in England did leap. William Wordsworth—then a youth of nineteen—conceived the high ideal that was sought by many who set loose the passions of the ignorant, and hoped within the lifetime of a generation to lift to its full height the race of man. He found his way to France, even took some part in the work of revolution; grieved over its failure, because his young spirit had seen heaven where Edmund Burke saw hell: the younger and the older man being alike sincere, alike inevitably drawn by bias of their minds to their appointed sides in the great controversy. The failure of the revolution did not fill Wordsworth with despair. While still cherishing his aspiration towards what Tennyson has since called a 'crowning race of man,' he came to feel that the way to such a race was long, since no state could be better than the citizens of which it is composed. But with unbroken hope he set himself to teach through verse the strength that grows out of the simple lives of men.

Thomas Campbell's *Pleasures of Hope*, in the last year of the 18th century, was a testament of hope left by the 18th century to the 19th. Wordsworth's *Excursion* in 1814, the year before Waterloo, was a poetical foreshowing of the work of individual development into which the 19th century should grow. In its own time it was little understood; but now we are abreast of it and understand it well. The tumult of the revolutionary spirit was in Byron; its pure ideal was in Shelley; its practical outcome was in Wordsworth; and a breath of health passed for the renovation of society wherever Walter Scott's novels were read. In the later days familiar to us all, it is enough to point to the continuous advance, through every form of literature, towards the raising of the people by the raising of the citizens whose lives are all in all. Open expression of the reaction against Latin-English and the diction encouraged by the period of French influence was in Wordsworth's defence by preface and appendix of the style of the *Lyrical Ballads*, first published in 1798. He argued, and he acted upon his belief, that there is no separate book language; that the best thoughts are best expressed in a selection of the words in ordinary use. Again and again he laid stress on the word 'selection.' He was misapprehended, and gave some little cause for misapprehension by a defiant use in his poems of words and phrases which his better judgment, when the critical war was over and his cause had triumphed, led him afterwards to alter.

The impulse out of which Scott's poetry and

Scott's novels grew it is usual to term Romanticism, as its most essential element was a revolt from the severity of classical form alike in choice and treatment of subjects for poetic expression. It was a revolt from the predominance of substance over form, towards a more emotional and fearless expression of the relations of the human soul to the mystery and romance of the world around it. The vivid directness and imaginative power of Percy's *Ballads* (1765) gave a rude shock to the dull didactics of the 18th century, and the imitative work of the young Chatterton also revealed what influence our earlier poetry could effect upon a capable imagination. Cowper and Burns revealed the capacity for poetic expression of simple, natural language, and the earliest creations of Blake's strange spiritual genius foreshadowed a romantic revival in literature and art, which was to give us in the poetry of Coleridge, Shelley, Keats, and Rossetti almost the greatest poetic triumphs of the next century. Scott's romance was a direct issue of romanticism, and a host of imitators, under the mighty spell of the same impulses that made our greatest novelist, carried reverence for the past to strange ends in literature, art, and even religion. Not the least gain has been that revival of interest in the earlier English language, which has revolutionised the modern study of our tongue and created anew an audience, no longer few, for Chaucer, and even the lesser Elizabethans. Englishmen have awoke to the fact that they possess a native literature infinitely richer in quality and larger in quantity than any people in the world, and the success of such publications as the admirable reprints of Professor Arber and the Universal and National Libraries of Professor Henry Morley prove that this knowledge even already is widespread.

The past has been studied and the future battled for with independent energy. Above all things truth must be found. History stands more and more pledged to an accurate inquiry into the trustworthiness of all its facts. Every statement must be traced to its original authority; that ascertained, let each man reason on it as he would. Greek history has been restudied by Grote and Thirlwall; Roman, by Merivale; the history of the Jews and of Latin Christianity by Milman; the history of England by Macaulay, Freeman, Stubbs, Froude, Brewer, Gardiner, Green. Buckle and Lecky have studied history and theorised upon it. The *Edinburgh Review* (1802) and the *Quarterly* (1809) inaugurated a new era of criticism. Science has made wonderful advance both in knowledge and in its application, as Francis Bacon would have it applied, to enlargement of the dominion of man. It has not only abounded in results of accurate research, but has developed a large power of generalisation founded upon patient experiment, by which especially Charles Darwin has influenced 19th-century thought.

In church questions there has been the same advance of fearlessness in the inquiry after truth, and the same strenuous endeavour to make truth bear fruit within the lives of men. Every tendency of religious thought has had its faithful representative in Whately, Keble, Pusey, Newman, Dr Arnold, Maurice, Dean Stanley, Canon Liddon, Dr Martineau, and many more. The periodical press has opened a free plain for ready encounter of all forms of thought in honest grapple with each other. There is even an increasing number of magazines founded upon the plan first adopted by George Henry Lewes in 1863, when he established the *Fortnightly Review*, for the free conflict of opposite opinions within the lists of a single journal. This good example was followed promptly, in 1866, by the establishment of the *Contemporary*

*Review*; and the *Nineteenth Century* appeared in 1877. With the increase of reading power, the novel of the 19th century has taken the place occupied in the 16th by the drama. Women among the novelists have come to the front in literature as earnest helpers to a better day, and novels have been used, perhaps too much, for study of the deepest problems of the time. Mrs Somerville in science, Mrs Browning in poetry, George Eliot in fiction, have marked the advance from days when, with few exceptions, only men took part in the mind-labour of successive generations. The civilising power of the highest literature has been diffused by the energies of vigorous and earnest men, William and Robert Chambers, Charles Knight, and others who are now continuing such labour. Side by side with the free literature of England, a sister literature has grown in America which adds its forces to our own. The volume of the mighty stream of English literature has increased into an expanse that can be shown here by no more than a vague suggestion of its breadth and the direction of its flow. Our last great period in English literature is marked especially by the variety of forms in which all writers who obtain a large hearing dwell on individual fidelity to duty, in a life that is sincere and simple, as the one way to the highest possible for man. It was so in all the writings of Thomas Carlyle, of Dickens, of Thackeray, of George Eliot, and of Matthew Arnold. It is so in Alfred Tennyson, whose *Idylls of the King* figure King Arthur throughout as Conscience, the king within the human breast. It is so in all the writings of Robert Browning, who warns by many forms of dramatic expression against the vague ideal; and who represents the poet in his highest utterances, as he is throughout all literature, the voice of the workman when he feels most deeply the meaning of his work.

American literature is dealt with under UNITED STATES, and there are paragraphs under AUSTRALIA and CANADA on the literature of those great British colonies. There are separate articles on BIOGRAPHY, the DRAMA, LETTERS, NOVELS, NEWSPAPERS, PERIODICALS, and ROMANTICISM; and the subject of English literature may be further studied in the articles devoted to the several authors named above, and to many others whom in such a sketch it is impossible to include.

See Thomas Warton's *History of English Poetry* (1774-78; new ed. 4 vols. 1872); J. Payne Collier's *History of Dramatic Poetry* (3 vols. 1831; revised and enlarged, 1871); Henry Hallam's *Introduction to the Literature of Europe in the Fifteenth, Sixteenth, and Seventeenth Centuries* (4 vols. 1837-39); Thomas Wright's *Biographia Britannica Literaria* (vol. i. Anglo-Saxon Period, 1842; vol. ii. Anglo-Norman Period, 1849); George Lillo Crall's *Sketches of the History of Literature and Learning in England* (1844-45), expanded in 1861 into a *Compendious History of English Literature and the English Language*; S. A. Allibone's *Dictionary of English and American Literature* (3 vols. Phila. 1859-71); Thomas Arnold's *Manual of English Literature* (1862); Hippolyte Taine's *Histoire de la Littérature Anglaise* (4 vols. 1863-64; translated by H. van Laun, 1871); William Minto's *Manual of English Prose Literature* (1872); A. W. Ward's *History of English Dramatic Literature to the Death of Queen Anne* (2 vols. 1875); T. H. Ward's *English Poets* (2d ed. 4 vols. 1883); Henry Morley's *First Sketch of English Literature* (1873; enlarged in 1886), and *English Writers* (4 vols. 1887-89); Leslie Stephen's *History of English Thought in the 18th Century* (2 vols. 1876); Stopford Brooke's *Primer of English Literature* (1880); Richard Willeker's *Grundriss zur Geschichte der angelsächsischen Literatur* (1885); Bernhard ten Brink's *Geschichte der englischen Literatur* (vol. i. 1877; translated by H. M. Kennedy, 1883; vol. ii. 1888); F. J. Bierbaum's *History of the English Language and Literature from the Earliest Times until the Present Day, including the Literature of North America* (Heidelberg, 1883); Gustav Körting's *Grundriss der Geschichte der englischen Literatur von ihren Anfängen bis zur Gegenwart* (1887); George Saints-

bury's *Elizabethan Literature* (1888); Edmund Gosse's *From Shakespeare to Pope* (1885), and *Literature of the Eighteenth Century* (1889); Henry Morley's *Library of English Literature* (5 vols. 1876-82); and Chambers's *Cyclopædia of English Literature* (2 vols. 4th ed. 1885).

**English River**, (1) an estuary on the west side of Delagoa Bay; (2) another name for the Churchill River (q.v.).

**Englishry**. The Danish conquerors of England drew a legal distinction between the Danes and the English; and in this point the Normans followed their example. 'The Englishry,' like 'the Jewry,' was a term of contempt. In cases of murder, the hundred was punished, unless it could make a 'presentment of Englishry,' showing that the person slain belonged to the conquered race. There are recorded cases in which the hundred incurred an additional penalty for declaring that a murdered 'Frenchman' was an Englishman. In process of time Normans and English became one people; and 'presentment of Englishry' was abolished in the reign of Edward III.

**Engrailed**, in Heraldry, a line composed of a series of little semi-circular indentations. When a partition line is engrailed, the points are turned upwards; when an ordinary is engrailed, they enter the field. Invecked is a partition line the contrary *a*, Fess engrailed; *b*, Fess invecked. of engrailed, with the points pointing downwards and inwards.

**Engraving**, in the strictest sense of the word, is the art of scratching or incising marks or figures upon tablets of any hard substance. Certain forms of the art—such as decorative engraving for purely ornamental purposes upon metal, engraved writing upon tablets for the purpose of record, gem-engraving for the production of signets, cameo-engraving, &c.—are of extreme antiquity. But, in its more especial and restricted sense, the word engraving is understood to designate the cutting or incising of designs upon metal plates or blocks of wood, for the purpose of printing impressions from them in ink upon paper, or other similar substance. Engravings of this sort are divided into the two broad classes of engravings on metal, in which the lines to be printed are sunk or incised, and engravings on wood, in which the lines to be printed appear in relief, the wood between them being cut away. In the former the plate, having been inked and wiped on the surface, retains the ink only in its hollowed lines, from which it is conveyed to the paper by the pressure of the printing-press; whereas in the latter only the elevated portion of the surface of the block is inked by means of a roller, and being subjected to the press, it prints as a raised type. [WOOD-ENGRAVING is fully described under its specific heading; here we deal only with *Engraving upon Metal*.]

The metal most commonly used for engraving has been copper; but during the 19th century steel has been largely employed on account of its hardness, which enables it to resist the wear of printing, and to throw off a far larger number of unimpaired impressions than could possibly be obtained from a copper plate. Steel, however, is less readily engraved upon than copper, and so is apt to yield a less free and artistic result; and, by means of a recent discovery, the surfaces of copper plates can now be protected by an extremely thin coating of steel deposited by galvanic action, which enables them to yield a large number of excellent

impressions without being worn. Zinc plates have also been employed to some extent for etchings, especially by Seymour Haden, a very eminent 'painter-etcher,' who likes the 'fat,' picturesque, and varied line which this metal yields when bitten by the acid.

The earliest of the impressions taken from engraved plates are those most valued by connoisseurs, on account of their sharpness, clearness, and richness, qualities which are gradually lost as the surface of the metal becomes worn by repeated printing. The term 'working proofs' indicates trial impressions printed by engravers for their own use, to test the state of their work during its progress. 'Artist's proofs' are those bearing the signature of the painter or engraver, or of both, which is held to guarantee the quality of the impression. 'Proofs before letters' are those thrown off before the printed titling, &c. has been added; and 'open letter proofs' are those in which the letters of the title have been added merely in outline.

#### THE PROCESSES OF ENGRAVING ON METAL.

*Line-engraving.*—The chief instrument of the line-engraver is the burin or graver, a small bar of steel, usually in the form of a quadrangular prism, pointed at one end, and with the other fixed in a rounded wooden handle. This instrument is held between the engraver's forefinger and thumb, which direct the motion of the point as it is pushed forward by the pressure of the palm of the hand on the wooden handle, and incises, upon the plate of polished metal placed beneath it, a line proportionate in breadth and depth to the amount of pressure used and the angle at which the point is applied, the metal being lifted clean out of the furrow in a long strip or shaving. In this manner the design is inscribed upon the plate: and, in printing, the plate is inked, its smooth surface is then wiped clean, so as to leave the ink remaining only in the incised lines, from which it is removed to paper by being passed through the printing-press.

*Etching.*—In this process a polished metal plate is coated with a thin transparent surface or 'ground' impervious to the action of acid. For this purpose a composition of white wax, gum-mastic, and asphaltum is usually employed, inclosed in a ball of silk. When this ball is applied to the heated surface of the plate, the ground melts and exudes through the cloth, and is spread evenly over the metal by means of a pad of cotton-wool covered with silk, termed a 'dabber.' The plate is then exposed to the smoke of wax tapers till it becomes of a uniform black colour, which enables the etched line, disclosing the shining metal, to be visible on its surface. Upon this plate, so prepared, the design is drawn with an 'etching-needle,' a sharp steel point fitted in a handle, and held like a pencil in the artist's hand. This needle removes the impervious ground where it is applied, disclosing lines of the bare metal, which are ready to be acted upon by the acid. The back of the plate having been protected by an application of Brunswick black, it is placed in the 'acid-bath,' a flat tray filled with a mordant, usually composed of nitric acid diluted with an equal volume of water, which attacks and corrodes the metal in the lines that have been exposed to its action by the needle. After sufficient time has been allowed for the palest lines of the subject to be bitten, the plate is removed from the bath; these lines are covered with a 'stopping-out varnish' of Brunswick-black, applied with a brush, which protects them from further action of the acid; and the plate is returned to the bath, which attacks the lines still exposed. This process is repeated as often as necessary to produce the

desired variety in depth of the various lines of the design. When the biting is completed, the plate is finally removed from the bath, the 'ground' is cleaned off by means of turpentine, and the design appears incised on the metal. The plate is then inked and printed in a manner similar to that employed in a plate engraved with the burin, those lines which have been longest exposed to the acid printing darkest, as they are the deepest and retain most ink. Much also can be done towards obtaining an artistic result by leaving a small coating of the ink on certain parts of the smooth surface of the plate, this film of ink printing as a delicate tint. If it should be found that the lines are too shallow, the plate may be regrounded by means of a roller charged with the 'ground' being passed over the plate. This coats the level surface with the impervious 'ground,' but leaves the incised lines free, so that they may be again subjected to the action of the acid in the bath.

During recent years various new methods of etching, and modifications of the process described above, have been introduced. These will be found clearly and fully described in P. G. Hamerton's *Etcher's Handbook*. In particular, a process for drawing the subject while the plate is exposed to the acid has been invented and much employed by Seymour Haden. He prepares the metal plate as above, and places it in a shallow bath filled with a mordant composed of hydrochloric acid, chlorate of potash, and water; and the subject is then drawn with the needle, the lines intended to be darkest being those first laid, so as to be longest exposed to the action of the acid.

It should be noticed that, while the early line-engravers worked with the burin alone, etching is combined with burin-work in most modern line-engravings; the subject being usually sketched with the etching-needle and bitten with acid, and the freer portions of foliage, &c. being also executed in a similar manner. 'Dry-point' is frequently employed in finishing the more delicate portions of line-engravings. The dry-point is an etching-needle sharpened in a particular way, and employed to scratch lines upon the bare metal. Unlike the burin, it does not cut a clean furrow out of the plate, but throws up the metal that it displaces in a ridge or 'bur,' which in printing yields a rich velvety blackness. When employed as an adjunct to line-engraving, this 'bur' is removed with the 'scraper;' and so treated, dry-point yields an extremely delicate line, very useful in finishing line-engravings and etchings. A 'ruling-machine' is also employed in producing the parallel lines representing flat skies in line-engravings.

*Soft-ground Etching.*—The metal plate is coated with ordinary etching-ground mixed with tallow, and a sheet of thin paper, with a certain degree of grain or texture in it, is stretched over the plate. The design is then drawn upon the upper surface of this paper with a hard black-lead pencil. On the paper being removed, it carries off adhering to its lower surface a portion of the etching-ground where pressure has been applied by the pencil-lines, exposing the metal of the plate, which is then bitten with acid, cleaned, and printed from, in the same manner as an ordinary etching. The impressions yielded by this process resemble a pencil-drawing or a lithograph.

*Mezzotint-engraving.*—This method differs from all other processes of metal engraving in that, while other engravers work from light to shade, and each line which they draw prints as a dark, the mezzotinter works from dark to light, and each touch which he adds to his plate prints as a light. Mezzotint-plates are prepared by the action of a kind of chisel, termed a 'cradle' or 'rocking-tool,'

which passing over its surface roughens it, raising a 'bur' of innumerable small metal points, so that if the plate were then inked and printed it would yield an impression of a uniform black. The engraver, having traced his subject on the plate, proceeds to smooth the surface by removing the 'bur' with a scraper, in proportion as he wishes to introduce light into his design; the bur being left untouched in the darkest shadows, partially removed in the half-lights, and wholly cleaned away in the high lights, in which the surface is perfectly smoothed, and brought to a high polish by means of the 'burnisher.' In modern mezzotint-plates, etching and work in stipple are frequently introduced, in a mistaken effort to obviate that softness and indefiniteness which is a characteristic of this method.

*Aquatint-engraving.*—In this process the polished metal plate is covered with a solution of iresinous gum dissolved in spirits of wine. The spirit evaporates, leaving the resin deposited in minute granulations on the metal surface. The design is then transferred to the metal, and the plate is bitten in a bath of diluted nitrous acid, which corrodes the portions left exposed between the grains of resin. The darkest parts of the design are longest exposed to the action of the mordant, the lighter parts being successively protected by a series of 'stoppings-out,' consisting of oxide of bismuth and turpentine varnish applied with a brush in a manner similar to that employed in the 'stopping-out' of an ordinary etching. The impressions produced resemble those yielded by mezzotint, both processes working by *spaces* and not by *lines*.

*Chalk or Stipple Engraving.*—The metal plate is coated with an ordinary etching-ground, and the subject is drawn upon it by means of a succession of small dots produced by the point of the etching-needle. The plate is then bitten in the usual way with acid, which corrodes the metal at the points uncovered by the needle; and it is afterwards finished by dots, applied with the point of the etching-needle or burin on the bare metal.

*Mechanical and Photographic Process.*—Engraving in recent times has suffered much from the rivalry of photographic and mechanical substitutes. The most important of these is known as photogravure or heliogravure. The beauty of the work produced by means of this process, in the reproduction of paintings, of drawings in monochrome made for the purpose, and of photographs direct from nature, has raised it to a position in which it bids fair, at no very distant date, to supersede engraving altogether; except in so far as the burin is used to touch up and finish the plates so produced. The processes employed will be described under PHOTOGRAPHY.

A photo-mechanical process which is much used in the reproduction of the plates of the older engravers and etchers, and in the production of intaglio etched plates from pen drawings, has been carried to great perfection, some of the work produced by Amand-Durand of Paris being quite equal to the finest hand etchings. A *positive* photograph is taken of the drawing or engraving to be reproduced (i.e. the lines are black, the whites clear glass); this is placed over a copper plate coated with a bituminous varnish, and exposed to the light. Where the lines of the photograph have protected the varnish from the light it remains soluble, but where the light has affected it through the glass it becomes insoluble. The varnish may then be dissolved from the lines, and the copper exposed exactly as if the etching-point had been used to make the drawing on an etching-ground. It is then etched in the usual manner, as already described, and finally touched up and improved with the graver.

There are many other mechanical and photographic processes of engraving, especially for the production of relief blocks, but as their connection with engraving is more or less remote, and they are all more or less used for the purposes of book illustration, it will be more convenient to devote a special article to describing such of them as are not well enough known by their distinctive names, to be separately treated. See the article ILLUSTRATION.

#### HISTORY OF ENGRAVING ON METAL.

*Line-engraving.*—The practice of engraving metal plates, for the purpose of printing impressions from them with ink upon paper, originated with the early Italian goldsmiths, who in this manner were accustomed to take proofs of the metal objects which they decorated with engraved designs, in order to test the progress of their work; and these *nielli* (see NIELLO), or decorated plates of metal, in which the hollows were finally to be filled in with a black enamel, are regarded as the earliest engravings. A *pac* or metal plate used in the Roman ritual to receive the kiss of peace, executed by Maso Finiguerra, in 1452, for the church of San Giovanni in Florence, is considered to have been the first metal from which impressions on paper are known to have been taken. This *pac* is preserved in the Uffizi at Florence, and the only known original impression from it is in the Bibliothèque de Paris. Works of *niello*, however, were only incidentally used for taking impressions on paper; they were primarily designed as metal decorations, but they supplied the necessary hint as to the possibilities of the process, and led the way to such works as the *Kalendar*, dated 1465, and ascribed to Baldini (c.1430–c.1480), and the plates in the *Monte Santo de Dio* (1477) and in an edition of Dante (1481), both of which are ascribed to Baldini and Botticelli (1447–1515), in which we see the beginnings of metal engraving properly so called. Among the other early Italian line-engravers were Antonio del Pollajuolo (1420–98), who executed a few very scarce prints, showing that command of the figure for which he was celebrated as a painter; Robetta (c.1510), whose works are excellent in design, though poor in *technique*; and Andrea Mantegna (1431–1506), whose productions are distinguished by an impressive gravity and by a dignified classical feeling. Most of these engravers were themselves painters, and engraved from their own designs; but in Marc Antonio Raimondi (c.1488–c.1530) we have an engraver in the modern sense, engaged in reproducing the works of other artists. He is mainly known by his noble transcripts of the works of Raphael, in which he was aided by the master himself, who sometimes corrected his outlines upon the copper. Among the modern line-engravers of Italy may be named John Volpato (1730–1803), known chiefly by his 'School of Athens' and other plates after Raphael; Raphael Morghen (1758–1833), whose most famous plate reproduces Leonardo's 'Last Supper,' though a finer work is his rendering of Van Dyck's portrait of Francesco de Moncada; Paul Toschi (1788–1854), celebrated for his transcripts of the frescoes by Correggio at Parma; and Louis Calamatta (1802–69), who worked much after Ingres.

Among the productions of the North we find an example of line-engraving upon metal earlier in date than any afforded by the schools of Italy. This is a 'Magellatian,' forming part of a Passional series, dated 1440, a work attributed to an engraver of Upper Germany. Among the other early German engravers are 'The Master of 1464 or of the Banderoles' and 'The Master of 1466 or of the Initials C. S.' But it is in Martin Schongauer (c.1420–c.1488) that we find the first really able

and accomplished master of the German school. His admirable works—very quaint, and full of the richest decorative feeling—are extremely scarce, but they may be studied in the excellent fac-similes executed by M. Amand-Durand of Paris. Along with Schongauer may also be named Israel von Meckenlen (c. 1480–1503), another prolific and excellent engraver. In Albert Dürer (1471–1528), however, we have the great master of the German school, alike in the admirably accomplished *technique* of his plates, in their nobility of design, power of draughtsmanship, and expressional qualities. Not far beneath him must be ranked Lucas van Leyden (1494–1533), a productive and talented workman with the burin, though he was inspired by a less lofty and profound imagination, and dealt with homelier subjects than his great contemporary. At the early age of fourteen he had already produced several very accomplished plates, and he worked unceasingly, both as painter and engraver, till his death at the age of forty. Under the influence of Dürer, there sprang up a school of engravers working after their own designs. These men, distinguished by a dexterous use of the burin, and by very considerable invention and decorative skill, are known, from the small size of their plates, as 'The Little Masters.' They include Albert Altdorfer (c. 1498–1538), Jacob Binck (c. 1490–1569), Hans Sebald Beham (1500–50), Bartel Beham (1502–40), Heinrich Aldegrever (1502–c. 1555), Georg Pencz (c. 1500–50), and Hans Brosamer (c. 1485–1552). In the end of the 16th century a notable school of line-engravers arose in Holland, among the members of which Henry Goltzius (1558–1617) produced portrait-engravings of extreme delicacy and finish, and Henry Hondius (c. 1573–c. 1662) is also favourably known for plates of a similar class; while Schelte Bolswert (born c. 1586), Paul Pontius (c. 1598), Lucas Vosterman (c. 1580), Peter de Jode (1606–60), and others were members of a school which owed its rise to the influence of Rubens. Among the more modern German line-engravers are Johann Georg Wille (1715–1807), Georg Friedrich Schmidt (1712–75), and Johann Christian Friedrich Wilhelm Müller (1783–1816), known by his fine rendering of the 'Madonna di San Sisto,' all of whom worked for a time in France.

In France some of the earliest line-engravings are the illustrations to a book by Breydenbach, published at Lyons in 1488, and reproducing woodcut views published at Mainz two years previously. Noël Garnier (working up till 1540) is known by his copies from the German engravers; but in Jean Duvet (1485–1561) France first possessed an engraver of real ability. Considerably influenced by Mantegna, he produced his 'Martyrdom of St Sebastian,' and his series of 'The Apocalypse' and of 'The Amours of Henry II.,' works of considerable inventive power. He was followed by Claude Corneille (c. 1550), Jean de Gournmont (c. 1550), Jean Cousin (1501–c. 1589), Pierre Woëriot (1532), and Etienne Delaune (1519–83), an able engraver who worked after Cousin, and is also known by his graceful hunting subjects and by his series of 'The Sciences' and the 'Twelve Months.' From such men we pass to the school of Fontainebleau, formed by Rosso and Primaticcio, of which, among the engravers, the most celebrated are Antonio Fantuzzi di Trento (1508–c. 1550), Léonard Tiry (working 1540–65), René Boyvin (1530–c. 1598), and Guido Ruggieri (working about 1570), Thomas de Leu (c. 1560–1612), and Léonard Gaultier (c. 1552–1641) may be named as good engravers of portraits, leading the way to the great school of French portrait-engravers in line of the 17th century, who carried the art to the utmost conceivable perfection of which their aims

and method admitted. Among these are Claude Mellan (1598–1688); Robert Nanteuil (c. 1623–78), one of the most spirited and manly engravers of that or of any time; Jean Murin (c. 1600–c. 1666); Gérard Elelinck (c. 1640–1707), a native of Antwerp, summoned to France by Colbert; Gérard Andran (1640–1703), the most able draughtsman of the school, who largely employed etching in combination with his burin-work; and Antoine Masson (1636–1700). The line-engravers of this period are seen at their highest in their portrait-subjects, which are delightfully spirited and intelligent in handling, and—being frequently, as was usually the case with Nanteuil's work, done *ad vivum*, or from the engraver's own drawing made from the life—possess the highest interest and authenticity as direct and original portraits. Following these men come a group of portrait-engravers who were more exclusively employed in rendering the works of painters, and whose work, absolutely skilful and accomplished as it was, rendering details and reproducing textures with unexampled exactitude and variety of touch, was yet somewhat less manly, direct, and simple than that of their predecessors. Among these were Pierre Drevet the Elder (1663–1738); Pierre Drevet the Younger (1697–1739), from whom we have a superb portrait of Bossuet, after Rigaud; and Jean Daullé (1703–63). To Wille, Schmidt, and Müller we have already referred as engravers of German nationality working in France. Laurent Cars (1702–71), Nicolas de Larnessin (1684–1756), Bernard Lépicié (1690–1755), and Pierre-Louis Surugue (1717–71) produced admirably faithful transcripts from the figure-pictures of Watteau, Chardin, and other contemporary painters. Charles-Nicolas Cochin (1713–88), in addition to similar work, executed a series of valuable medallion portraits of most celebrated men of the time; and Jacques-Philippe Lebas (1707–83), Claude-Augustin Duflos (1701–84), Pierre-Philippe Choffard (c. 1729–1809), and Augustin de Saint-Aubin (1738–1807) transcribed with vivacity the vignette book-illustrations of Gravelot and Eisen. In more recent times Louis Copia (1764–99) and Barthélemy Roger (1770–1840) ably engraved the works of Prud'hon; Charles-Clement Bervic (1756–1822) was an accomplished pupil of Wille, influenced by the classical revival inaugurated by David; after whose works Pierre-Alexandre Tardieu (1756–1844), another pupil of Wille's, engraved much, though his most important plate is 'The Earl of Arundel,' after Vandyck. In our own time Auguste Boucher-Desnoyers (1779–1857) has produced many thoroughly accomplished plates, chiefly after Raphael; and Louis Calamatta (see above), Paul Mercuri, another Italian engraver working in France, and Achille-Louis Martinet (1806–77) have also been most skilful engravers.

Among the earliest line-engravings published in England are the copperplates in 'The Birth of Mankind' (1540), and in a translation of Vesalius's *Anatomy* (1545), the illustrations of the latter having been copied from the original woodcuts by Thomas Geminus, who was also the translator; but William Rogers (c. 1545) is usually regarded as the first English line-engraver of mark. He is best known by his full-length of Queen Elizabeth, after Oliver. Several members of the De Passe family settled in England in the middle of the 17th century; and Renold Elstracke (c. 1620) and Francis Delarm (1590) were the chief engravers of the scarce and interesting historic portraits in Holland's *Basilologia* (1618). A more important name is that of William Faithorne the Elder (1616–91)—a pupil, while in France, of Nanteuil's—among whose works is a portrait of Milton, '*ad vivum delin. et sculpsit, 1670.*' His plates lead us to those of William Hogarth (1697–1764), whose burin

engraved, in a sound, honest, and straightforward fashion, many of the figure-subjects executed by his brush.

Next comes a group of far more accomplished engravers, who worked in a classic and finished, if somewhat formal manner. Among these are Sir Robert Strange (1721-92), known mainly by his transcripts from the Italian masters; William Woollett (1735-85), seen at his best when reproducing the landscapes of Claude and Richard Wilson; and William Sharp (1749-1824): while William Blake (1757-1827), a true and sensitive 'painter-engraver,' won an abiding place in the history of the art by his 'Illustrations of the Book of Job.' The end of the last century and the earlier part of the present is distinguished by the achievements of the great school of English landscape-engravers in line founded by William Radclyffe (1780-1855), and including Robert Brandard (1805-62), J. T. Willmore (1800-63), and William Miller (1796-1882), whose admirable artistry translated with the most finished skill the subtlest cloud-effects of Turner. The vignette illustrations to Rogers's *Italy* (1830) and *Poems* (1834) are marvellous examples of the work, on a minute scale, of this school of engravers. Since the period of these men, line-engraving has declined in England, the popular demand now running more in the direction of etching and of various photographic reproductive processes; but within recent years we have had such accomplished burinists as G. T. Doo (1800-86), Lamb Stocks (born 1812), and C. H. Jeans (1827-79). In America, which now possesses a singularly dexterous school of wood-engravers, and also several talented etchers, comparatively little of artistic worth has been produced in line-engraving. Here the process has been chiefly used for book illustration, and for the reproduction of portraiture; and many of its practitioners have been artists of British nationality. For an account of American engravers, see W. S. Baker's *American Engravers and their Works* (Phila. 1875).

*Etching.*—Albert Dürer (1471-1528), so prolific as a line-engraver and a woodcut-designer, has also the distinction of being the earliest artist who used the process of etching; but the first—and as yet unequalled—master in this department is Rembrandt (1607-69), who, alike in portrait and subject etchings and in his rarer etched landscapes, is the perfect example of what a 'painter-etcher,' an etcher working direct from nature or from his own designs, should be. Much also was done by the pupils and immediate successors of Rembrandt, by such men as Ferdinand Bol (c. 1611-81), Philip de Koninck (1619-89); and later Adriaen Janszoon van Ostade (1610-85), Cornelis Pietersz Bega (1620-64), Nicolaas Berchem (1620-83), Paul Potter (1625-54), and Renier Zeeman (born 1612) all executed etchings worthy of preservation and study. By Van Dyck's own hand (1599-1641) is a series of masterly etchings from his portraits, plates which were afterwards completed by the burins of professional engravers. Daniel Nicolaus Chodowiecki (1726-1801), a most prolific etcher, born at Danzig, and working in Berlin, is known by his admirably spirited and graceful book-illustrations. In our own time, Jan Barthold Jongkind and Carel Nicolaas van 's Gravesande have produced landscape-etchings in essential sympathy with the work of the early Dutchmen; and Professor Wilhelm Unger is favourably known as an etcher from paintings.

In Claude (1600-82), an Italian working in France, we have an etcher who infused into his work with the needle much of that delicacy and tenderness of tone and atmosphere for which his work with the brush is pre-eminent: and Jacques

Callot (1592-1635) was a spirited and prolific etcher of figure-subjects. During the 18th century the sound traditions of etching seem to have been forgotten, and its true capabilities forgone in France and elsewhere; and the revived practice of the art, upon correct lines, dates from about 1840, when painter-etchers like Charles Daubigny (1817-78) and Charles Jacque (born 1813) began to find, in a periodical entitled *L'Artiste*, an outlet for the plates which they had etched for mere love of the process and of its artistic possibilities. The *Gazette des Beaux Arts*, established in 1857, is also intimately associated with the revival of the art in France, as was also M. Cadart, the Paris publisher. Among the more eminent of the modern French etchers may be named Charles Méryon (1821-68), known by his 'views' of Paris, 'views' which are also visions; Maxime Lalanne (1827-86), one of the most graceful masters of the point; Veyrassat; Félix Braquemond (born 1833), a robust and vigorous etcher; and Jules Jacquemart (1837-80), celebrated for his delicate and sensitive renderings of old jewellers' work and other precious objects of still-life, as well as for his transcripts from pictures. We have here spoken mainly of the painter-etchers, but etching, of a particularly skilled and dexterous sort, has been largely employed in Paris as a finer, swifter, and less mechanical method than line-engraving for the reproduction of paintings. Among the most skilled of the French reproductive etchers are Leopold Flaming, Paul-Adolphe Rajon (1842-88), Charles Waltner, and Le Rat.

In England, the first representative etcher is Wenceslaus Hollar (1607-77), a native of Prague, brought to this country by the Earl of Arundel in 1637. He worked under the constant pressure of extreme poverty, and much that he produced was beneath his best powers; but the finest of his prints are monumental and exemplary as specimens of the art. 'People sometimes say to me, "What is it you see in Hollar?" and I always reply, "Nearly everything,"' writes Seymour Haden. During the years that succeeded Hollar, the true spirit of the process was lost sight of in Britain, as abroad; though the mere processes of the art were kept alive by their use in preparation and subordination to line-engraving, and by the practice of such etchers as Thomas Worlidge (1700-66) in England, and David Denchar and John Kay (1742-1826) in Scotland. It was Andrew Geddes, A.R.A. (1783-1844), whose example first gave a wholesome and vigorous stimulus to the practice of the art; and, in particular, he produced some most effective work in dry-point. Such of the etchings of David Wilkie, R.A. (1785-1841), as the 'Gentleman at his Desk,' are excellent in aim and spirited in treatment; but both Geddes and Wilkie must be studied in the scarce original states of their plates, not in the much-worn issue of 1875. Turner (1775-1851) used etching with admirable power and unerring selection of line in the plates of his *Liber Studiorum*, where the light and shade was afterwards added by mezzotint, applied usually by the hand of a professional engraver. A considerable stimulus was given to the art in England by the establishment of the Etching Club, which began to publish portfolios in 1841; and still more by the publication, in 1868, of P. G. Hamerton's *Etching and Etchers*, and the establishment of the *Portfolio*, a magazine chiefly devoted to etchings, under his editorship, in 1870. The Etching Club included in its membership such able etchers as Samuel Palmer (1805-81), J. C. Hook, C. W. Cope, and Seymour Haden, an amateur who ranks with James M.N. Whistler at the very head of the painter-etchers working in England. Alphonse Legros and Hubert Herkomer have also done much to stimulate interest in the

art, both by the example of their works and by direct manipulative tuition. Among the younger of our able painter-etchers are William Strang and Frank Short, the former reminiscent in his work of Legros, the latter of Whistler. The more distinctively reproductive etchers include R. A. Macbeth, known by most important transcripts from Frederick Walker and George Mason, and from the works of Titian and Velasquez in Madrid and London; while Mortimer Menpes has rendered 'The Banquet of the Officers of the Archers of St Adrian' of Frans Hals in the largest dry-point on record, as well as produced many independent plates, notably two series of Japanese subjects. Among the earlier of the artists who practised etching in America may be named William Dunlap (1766-1839), the historian of American art; George L. Brown (q.v.), known by his nine 'Etchings of the Campagna, Rome' (1860); and Edwin Forbes, who, about 1876, published a portfolio of forty plates of 'Life Studies of the Great Army.' In 1866 M. Cailart of Paris established a French Etching Club in New York, which did a good deal to foster the art. The *American Art Review*, founded in 1879, during the two years of its existence afforded a means for the publication of etchings; and in 1881 an interesting exhibition of the works of American etchers was held at the Boston Museum of Fine Arts. Among the most talented of recent etchers in America may be named Frank Duveneck, who has produced some admirable Venetian street-scenes, Otto Bacher, Henry Farrer, Joseph Pennell, Stephen Parrish, Mary Nimmo Moran, Thomas Moran, and Charles Platt.

*Soft-ground Etching.*—This process was effectively employed by John Sell Cotman (1782-1842) in his architectural subjects, by Samuel Prout (1784-1852), and by John Ruskin (q.v.) in the illustrations to the first edition of his *Seven Lamps of Architecture* (1849); but it has now been superseded by lithography, which attains similar results in a readier way, and is much less costly in printing.

*Mezzotint.*—The process of mezzotint was invented by an amateur, Ludwig von Siegen (born 1609, at Utrecht), an officer who held the appointment of 'Kammerjunker' to the Landgrave of Hesse-Cassel. In 1642 he forwarded to his patron a portrait of his mother, the Dowager Landgravine of Hesse, as the first-fruits of his newly-discovered process, stating, in the letter which accompanied it, that 'how this work was done, no copperplate-engraver or artist can explain or imagine.' In 1654, after having executed other plates in the same manner, Von Siegen visited Brussels, and there came into contact with Prince Rupert (1619-82), who had already been practising etching, and to him, for the first time, the inventor disclosed his process. It was adopted by the prince, who was assisted by Wallerant Vaillant (1623-77), and was afterwards practised by Theodore Caspar von Fuerstenberg, one of whose plates is dated 1636; Johann Thomas of Ypres, who is stated to have acquired the art at Frankfort; Abraham Blooteling (1634-c.1695), an admirable engraver of portraits, who worked for a time in England; Gerard Valk (1626-c.1720); and by many of the leading Dutch painters and engravers of the century. During the 18th century mezzotint-engraving declined in Holland, and, indeed, on the Continent generally, though Jacques Christoffe Le Blon (born 1670 at Frankfort, died 1741 at Paris) devised a process for printing mezzotints by means of which various colours of ink appeared in each impression. The art was to some extent revived in Vienna, about 1780, by Jacobo, who had studied in London under the great English mezzotinters of the period; and, in the same city, Johann Peter Pichler (1765-1806) executed some

admirable plates, particularly his transcripts from the flower-pieces of Van Huisum.

In France we have mezzotint-plates by J. Van der Bruggen (born 1649, at Brussels), dated from Paris as early as 1681. Sebastian Barras (born c.1680 at Aix; died 1710), Isaac Sarrahat (working 1695-1701), and Bernard Picart (1673-1733) are other mezzotint-engravers who worked in France; but here the process was comparatively little used on account of the great excellence of the French line-engravers.

It was, however, in England that the art was most extensively and successfully practised, as is indicated by one of the phrases used on the Continent to designate mezzotint-engraving, *la manière anglaise*. The process was introduced in 1660 into England by Prince Rupert, whose method is described in Evelyn's *Sculptura, or the Art of Chalcography* (1662). He executed some fifteen plates, among which the chief are the 'Great Executioner' and the 'Standard-bearer.' Sir Christopher Wren (1631-1723) and John Evelyn (1620-1706) have been believed, on rather insufficient evidence, to have practised the art. William Sherwin's plate of Charles II. is dated 1669; Francis Place (1650-1728) scraped a few portraits, including one of Charles I., free in style and delicate in gradation; Isaac Beckett (1653-1719), and particularly John Smith the Elder (1652-1742), worked much after the portraits of Kneller; and John Faber the Younger (born in Holland, 1684; died in London, 1756) engraved series of 'The Beauties of Hampton Court' and 'The Members of the Kit-Cat Club' after the same artist, transcribed the portraits of many minor portrait-painters of the time, and also engraved many subject-pictures, one of the finest being a mezzotint from Frans Hals's 'Man playing the Guitar' (1754). Richard Earlom (1743-1822) is seen at his highest in his mezzotints from Dutch flower-pictures, prints which are unrivalled for delicacy; and among his other works are his reproductions, in combined etching and mezzotint, of Claude's *Liber Veritatis* drawings. We have now reached the perfect time of the art in England, the period of the great school of mezzotinters who reproduced with splendid power the works of Reynolds and his contemporaries, with whose style of painting, with whose broad generalising touch, the method of mezzotint is in most essential sympathy. Among the greatest of these men are James M'Arden (1710-65), by whose prints Reynolds said 'I shall be immortalised,' Edward Fisher (1730-85), James Watson (1740-90), John Jones (1740-1810), J. Raphael Smith (1750-1812), Valentine Green (1730-1813), William Dickinson (1746-1823), S. W. Reynolds (1773 or 1774-1835), and Charles Turner (1773-1857). The mezzotint-prints executed after Sir Joshua alone include the work of about sixty different engravers. Some of these men, such as Charles Turner and S. W. Reynolds, took part in the plates of the *Liber Studiorum* of J. M. W. Turner (himself an accomplished mezzotinter, as certain plates of that series attest), and engraved the portraits of Raeburn, works especially adapted for reproduction by their method; and William Ward (1766-1826) scraped a few splendid prints after another Scottish painter, Andrew Geddes. The latest and most effective development of pure mezzotint in landscape includes the renderings by Thomas G. Lupton (1791-1873) of Turner's 'Ports' and 'Rivers' of England, and the transcripts by David Lucas (1802-81) from the works of Constable, a series executed, like the *Liber Studiorum* of Turner, under the closest supervision of the painter; who, however, did not, like Turner, himself use the scraper, though he longed to do so, writing to his engraver, 'How I wish I could scratch and tear

away with your tools on the steel.' On account of the larger number of impressions which could be printed from them, steel plates had already been introduced by the mezzotint, but these being scraped with somewhat less facility than the copper plates formerly employed, tended much to the deterioration of the art and to the loss of its especial qualities of freedom and painter-like breadth, especially when the mezzotint work was largely supplemented, as was now commonly the case, by the burin, and by etching and stipple-engraving. By means of this modern method engravers of first-rate power, such as Samuel Cousins (1801-87), were capable of producing attractive and excellent plates; but in the hands of inferior workmen the results attained by this hasty combination of various processes were pitifully inartistic. Within quite recent years, however, there has been a distinct revival of the art upon the old legitimate lines of pure mezzotinting upon copper. One of the first inaugurators of the revival was Joseph Jossey, who engraved very sympathetically Whistler's 'Thomas Carlyle' and 'Portrait of the Artist's Mother.' William Campbell (1855-87) executed several excellent mezzotints after Burne-Jones. A powerful impetus towards right technical methods was given by Hubert Herkomer (born 1849 in Bavaria), and among his pupils D. Wehrschmidt and William Henderson have engraved excellently after Holl's portraits, and Gerald Robinson is favourably known by his delicate transcript from Van Dyck's bust portrait of Henrietta Maria in the royal collection. Seymour Haden has added mezzotint to the later stages of his powerful etching from Turner's 'Calais Pier,' and F. Short, in addition to original work, has produced, in combined etching and mezzotint, some admirable copies from Turner's *Liber Studiorum*. Mezzotint was the first form of engraving practised in America, Peter Pelham (c. 1684-1751) having removed from London and settled in Boston before 1727, the year in which he published, from his own painting, a mezzotint of the Rev. Cotton Mather, which was followed by various other portraits of eminent Americans. Among the other mezzotint engravers of America may be named Thomas B. Welch (c. 1814-74), and John Sartain (born in London, 1808).

*Aquatint-engraving.*—This method is believed to have been invented by Jean-Claude-Richard de Saint-Non (1730-1804), a French draughtsman and etcher who studied in Italy, and to have been communicated by him to Jean Baptiste Le Prince (1733-81), a native of Metz working in Paris, who sold the secret to the Hon. Charles Greville. By him it was disclosed to Paul Sandby, who was the first to practise the method in England, using it to reproduce his Welsh landscapes, and carrying it to great perfection in his 'Views in the Encampments in the Parks' (1780). It was also employed in Scotland by David Allan (1744-98), who engraved in this manner his illustrations to Ramsay's *Gentle Shepherd* (1788). F. C. Lewis (1779-1856), the best aquatint-engraver of his time, is known by his reproductions of the drawings of Claude and of Lawrence; and he added the aquatint light-and-shade to the first plate of Turner's *Liber Studiorum*, mezzotint being employed for this purpose in the rest of the subjects of the series. Catherine Prestel (died in London, 1794), a German, executed some fine plates in combined etching and aquatint; and in Spain Goya (1746-1828) employed a similar union of processes in the wild and bizarre plates which he produced. Aquatint is now little used, but in our own time Brunet-Debaines has adopted it with accomplished skill in his renderings of the landscapes of Turner.

*Chalk or Stipple Engraving.*—Jean Charles

François (1717-69) is said to have been the first engraver to employ this process, and for its discovery he received a pension of 600 francs from the French king, along with the title of 'Graveur des desseins du Cabinet du Roi.' He used the method chiefly for the reproduction of drawings in crayons, for which it has since been very popular until the discovery of Lithography (q.v.) and of Photography (q.v.), by which such fac-similes can more accurately and readily be produced. He was followed by Giles de Martean the Elder (1722), another able engraver. The process was introduced into England by William Wynne Ryland (born 1732; executed for forgery, 1783), who worked in this method after drawings by the old masters and the designs of Angelica Kauffman; but the most celebrated of the stipple-engravers working in England was an Italian, Francesco Bartolozzi (1725-1815). In America some good portrait engraving in stipple was produced by David Edwin (1776-1841), an Englishman who studied in his native country and in Holland, and by Ion B. Forrest (1814-70), a Scotsman trained in London.

The works dealing with the history and practice of engraving are very numerous, and every year adds many fresh volumes upon the subject. In Dr W. H. Visslure's *Introduction to the Study and Collection of Ancient Prints* (2d ed. 1877), a useful book of reference, will be found a list of nearly a hundred works devoted to engraving. For an account of technical processes, the student may consult T. H. Fielding's *Art of Engraving* (1841), P. G. Hamerton's *Etcher's Handbook* (1871), the three editions of his *Etching and Etchers*, and his *Graphic Arts* (1882). *Le Peintre-Graveur* of Adam Bartoli (Vienna, 1803-21, and Leipz. 1854), with its supplements by J. D. Passavant (6 vols. Leipz. 1860-64), and A. P. F. Robert-Dumesnil's *Le Peintre-Graveur Français* (8 vols. Paris, 1835-50), and the 11 volumes of its continuation by Georges Dupleix, are the standard catalogues of old prints. Among the other works that may be named are W. Y. Ottley's *Early History of Engraving* (2 vols. Lond. 1816); Georges Dupleix's *Histoire de la Graveur en France* (Paris, 1861), *Les Merveilles de la Graveur en France* (Paris, 1869), and *Histoire de la Graveur* (Paris, 1880); and Bryan's *Dictionary of Painters and Engravers* (edited by R. E. Graves and W. Armstrong, 2 vols. Lond. 1886-89); and there are separate monographs and catalogues dealing with the works of almost all the more important individual engravers. The extensive series of fac-similes by M. Amand-Durand of Paris from the plates of many of the old engravers should be studied by those to whom the original prints are inaccessible.

**Engrossing**, a term used to describe the conduct of those who buy up merchandise in large quantities to obtain command of the market. This was formerly an offence punishable by law and by municipal regulations; as were also the offences of forestalling (buying merchandise on its way to market) and badgering or regrating (buying to sell again at an unduly enhanced price). The old laws in restraint of trade were not found to work well. So far from making the necessities of life cheap as they were intended to do, they discouraged producers and traders, and so made prices abnormally high. The English statutes on the subject were therefore repealed in 1772, and the offences of engrossing, &c. were finally abolished, both in England and in Scotland, in 1844. In the United States, engrossing is a common-law offence; and the constitutions of several states declare that monopolies are 'contrary to the genius of true government'; but with the development of modern commerce these restrictions have become obsolete, and 'rings,' 'corners,' 'syndicates,' 'trusts,' are year by year becoming more common on both sides of the Atlantic.

**Engrossing a Deed** means the writing it out in full and regular form on parchment or paper for signature. The person who engrosses is usually a law-stationer or clerk. In Scotland, the

corresponding term is 'extending a deed,' and till 1874 it was necessary that the person extending the deed should be named in the testing clause. See **DEED**.

**Enharmonic**, originally the name of one of the three Greek scales, is now applied to music constructed on a scale containing intervals less than a semitone—e.g. where the difference is recognised between G $\sharp$  and Ab, or D $\sharp$  and Eb. On the old organ built by 'Father' Smith for the Temple Church in London these notes had separate keys. But in modern keyed instruments, tuned, as they now universally are, in equal temperament, these notes are represented by the same sound; and the possibility is afforded of enharmonic *modulation*, in which a chord belonging to one key is, by a change merely of its notation, made the means of passing into another key. The chords commonly used in this change are the diminished seventh, or equivocal chord, which may be written in four different ways, and (less frequently) the dominant seventh, which may be changed into the German sixth. See **MUSIC**.

**Enkhuizen**, a town of North Holland, one of the 'deal cities of the Zuider Zee,' 35 miles NNE. of Amsterdam. It once sent out 400 ships to the herring-fishery, and had 40,000 inhabitants; but its harbour has gradually silted up. It was the first town to throw off the Spanish yoke (1572), and in 1625 was Paul Potter's birthplace. Pop. 5751.

**Enlistment** is the mode by which the British and American army is recruited, as distinguished from the Conscription (q.v.) prevailing in most European countries. Enlistment in Britain was, until 1802, in the hands of middlemen, who received a commission for their trouble. Since that year it has been managed by the adjutant-general's department. Formerly, a soldier enlisted for life, and could never look forward to retiring on a pension while still possessed of a fair share of health and strength. This was changed in 1847 by an act which limited the term of enlistment to 10 years for infantry, and to 12 for cavalry or artillery. A soldier could then either quit the army without pension, or re-engage for the remainder of 21 years, at the expiration of which time he was entitled to a pension for life; and in 1868 twopence a day was added to the pay of every soldier so re-engaged. This system was not compatible with the formation of trained reserves, with which to bring the army to fighting strength in the event of war, and in consequence the 'Army Enlistment Act' of 1870 was passed. Under this act men still enlist for 12 years, but with the understanding that 7 years or less shall be passed with the colours, and the remainder in the reserve. This is known as 'short service'; and a reserve of trained soldiers has thus been formed who are liable to be called back into army service if great emergency arises during their reserve service. The Army Act of 1881 contains the law relating to enlistment. The Recruit (q.v.) no longer receives from the recruiting-sergeant the shilling which formerly obliged him to appear before a magistrate and take the oath, or pay a fine of twenty shillings. Now he is not deemed to be enlisted until he has voluntarily appeared before a magistrate, commanding officer, or other authorised person, who puts to him a series of authorised questions, and satisfies himself that the man is not under the influence of liquor. The recruit then signs the declaration, takes the oath, and is attested. A false answer to questions put on attestation is punishable by a civil court or court-martial. At any time within three months of his attestation if a recruit pays a sum not exceeding ten pounds he is entitled to be discharged, unless the country is at war. A man who has received

pay as a soldier is deemed to be enlisted, even though he has not been attested, but can claim his discharge at any time within 3 months. An apprentice can be claimed by his master within one month of his enlistment, but must be under 21, have been bound by regular indenture for 4 years, and under 16 when so bound. Militiamen enlist for a term of 6 years, and may then re-enrol for another term of 6 years. See **DESERTION**, **DISCHARGE**, **FOREIGN ENLISTMENT ACT**, and **RECRUIT**; and for the manning of the navy, see **NAVY**.

**Enna**. See **CASTROGIOVANNI**.

**Emmoser**, JOSEPH, a medico-philosophic writer, was born in 1787 at Hintersee, in the Tyrol, and commenced his medical studies at Innsbruck in 1806. On the rising of the Tyrolese against the French in 1809 he followed Andreas Hofer as his secretary; at the close of the war he went to Erlangen, and subsequently to Vienna, for the purpose of concluding his studies. In 1813 he raised a company of Tyrolese marksmen, who were of great service during the campaigns that followed. After the peace of Paris he finished his curriculum at Berlin, and devoted himself to the study of animal magnetism. In 1819 he was made professor of Medicine at Bonn, where he lectured until 1837; he then practised for a time at Innsbruck, but in 1841 removed to Munich, where he obtained a great reputation by the application of hypnotism as a curative power. He died 19th September 1854. Among his numerous writings *Der Magnetismus in seiner geschichtlichen Entwicklung* (Leip. 1819) is reckoned his principal work.

**Ennis**, a municipal borough of County Clare, Ireland, on the Feigus, 25 miles NW. of Limerick, and 151 WSW. of Dublin by rail, is a neat town, with some good houses. Here are the Catholic cathedral of Killaloe diocese, a fine court-house, the Clare Infirmary asylum, large flour-mills, a school founded by Erasmus Smith (1689), a column to O'Connell (1863), and a memorial to the 'Manchester martyrs.' Till 1885 Ennis returned one member to parliament. Pop. (1851) 7840; (1881) 6307.

**Enniscorthy**, a market-town of Wexford, beautifully situated on the navigable Slaney, 78 miles S. of Dublin by rail. A cruciform church by Pugin, with a good spire, is the principal edifice. There is a large corn-trade. Pop. (1851) 5993; (1881) 3666. Enniscorthy grew up round a castle, still entire, founded by Raymond le Gros, one of the early Anglo-Norman invaders. Cromwell took it in 1649; and the rebels from Vinegar Hill (q.v.) stormed and burned it in 1798.

**Enniskillen**, a municipal (till 1885, also parliamentary) borough, the capital of County Fermanagh, 87 miles WSW. of Belfast, and 117 NW. of Dublin by rail, is beautifully situated on an isle in the river between Upper and Lower Loughs Erne. Around are richly cultivated eminences and many fine mansions; whilst among its own edifices are the Protestant and Catholic churches (the latter a fine modern building), the large barracks, a lofty monument to Sir Lowry Cole, and the Royal Portora School. The chief manufactures are cutlery and straw-plait. Pop. (1851) 5792; (1881) 5712. Enniskillen is famous for the victory, in 1689, of the troops of William III., under Lord Hamilton, over a superior force of James II., under Lord Galway. The banners taken in the battle of the Boyne hang in the town-hall. The regiment of Enniskilleners, or 6th Dragoons, was first instituted from the brave defenders of the town.

**Ennius**, one of the earliest Roman poets, the father of the Roman Epics, was born at Rudiae, in Calabria, about 240 B.C., and was probably of

Greek extraction. He is said to have served in the wars, and to have risen to the rank of a centurion. In Sardinia he became acquainted with Cato the Elder, and returned with him to Rome when about the age of thirty-eight. Here he gained for himself the friendship of the most eminent men, among them Scipio Africanus the Elder, and attained (what was then exceedingly rare in the case of an alien) to the rank of a Roman citizen. He supported himself in a decent but humble manner by instructing some young Romans of distinguished families in the Greek language and literature, his accurate knowledge of which explains the influence he had on the development of the Latin tongue. He died when he had attained the age of seventy, about 170 B.C. His remains were interred in the tomb of the Scipios, and his bust was placed among those of that great family. Ennius tried his powers in almost every species of poetry, and although his language and versification are rough and unpolished, these defects are fully compensated by the energy of his expressions and the fire of his poetry. His poems were highly esteemed by Cicero, Horace, and Virgil: the last, indeed, frequently introduces whole lines from the poetry of Ennius into his own compositions. His memory seems to have been lovingly cherished by his countrymen: *Noster Ennius*, 'Our Ennius,' they used to call him. Of his tragedies, comedies, satires, and particularly of his *Annales*, an epic in 18 books, only fragments are extant. What adds to our regret is that it is believed his whole works were extant as late as the 13th century. The fragments have been collected and edited by Vahlen (1834) and by Lucian Müller (1885); the dramatic fragments by Ribbeck (1873). See also Lucian Müller, *Quintus Ennius* (1884); Ribbeck, *Römische Tragödie* (1873); Sellar's *Roman Poets of the Republic* (2d ed. 1881); and Simeon's *History of Latin Literature* (1882).

**Enns**, a river of Austria, rises at the northern base of a branch of the Noric Alps in the crown-land of Salzburg, 12 miles S. of Radstadt, and flows 190 miles (only the last 20 navigable) in a general northerly direction, till it joins the Danube a few miles below Linz. Its chief affluents are the Salz and the Steier. From ancient times the Enns has formed the boundary between Upper Austria (Ober der Enns) and Lower Austria (Unter der Enns). Having mostly a rapid fall, it is chiefly important from the valuable water-power which it supplies.

**Enoch**, 'the seventh from Adam' (Jude, xiv.), 'walked with God' (Gen. v. 21-24), and, after a life of 365 years, 'was not, for God took him'—i.e. (according to Heb. xi. 5) 'was translated that he should not see death.' This early tradition recorded in Genesis is a significant expression of the faith that man when he has attained to true unity with God is capable of an eternal divine life. It is probable that the number of the years of Enoch was in some way connected with the number of days in the solar year. Partly from this, and partly from the interpretation of his name (Heb. *Hanōk*) as 'initiated,' arose the later Jewish legend that Enoch had invented writing, arithmetic, astrology, and astronomy. He was held to have predicted the flood, and to be the possessor, through revelation, of the knowledge of all mysteries in heaven and earth. By the Arabs he is called *Idris* ('the experienced' or 'learned').—Enoch is the name of three other persons in the Bible, one of them being the eldest son of Cain (Gen. iv. 17).—For the Glasgow 'St Enoch,' a corruption of 'St Thenaw,' the name given by St Serf to St Kentigern's mother, see the article KENTIGERN.

**Enoch**, THE BOOK OF, purports to be a series of revelations made to Enoch both in heaven and on earth. Its contents embrace an apocalyptic history of the kingdom of God, and of the secret origin of the laws of nature. The book is not all by one author, and its various parts are largely interspersed with interpolations. It has been divided by scholars into (1) *an original writing*, consisting of chapters i.-xxxvi. and lxxii.-cv., of which at least chapters lxxxv.-xc. date from the last third of the 2d century B.C.; (2) *three allegories*, which are probably pre-Christian writings, but not earlier than the time of Herod, embracing chapters xxxvii.-lxxi., with the exception of later chapters liv. 7-lv. 2, and lx. 65-lxix. 25, which are distinguished as (3) *the Noahian portions*, because they purport to have been written by Noah. To these last should be added chapters cvi. cvii., and the still later chapter cviii.

The Book of Enoch, which, according to Dillmann, is of Palestinian origin, forms one of the richest sources for the knowledge of Jewish theology and speculation in the last ages before Christ. It was much used in Jewish and Christian writings of the first five centuries of our era, and a passage from it is quoted in the Epistle of Jude (verses 14, 15). Yet from about 800 A.D. the book disappeared, and only a few fragments of a Greek version (probably from a Hebrew or Aramaic original) were known till the year 1773, when three MSS. of an Ethiopic translation made from the Greek were brought by the traveller Bruce from Abyssinia. An English translation by Archbishop Lawrence appeared in 1821 (Ethiopic text, 1838). The best edition is that of Dillmann, based on a collation of five MSS. (Leip. 1851), which, with his German translation (1853), has formed the foundation of all subsequent studies on the book.

See Drummond, *The Jewish Messiah* (1877); Bissell, *The Apocrypha of the Old Testament* (New York, 1880); Schodde, *The Book of Enoch*, a translation with introduction and notes (Andover, 1882); vol. iii. of Stanley's *Jewish Church* (new ed. 1883); and the account both of the book and of the recent literature relating to it in Schürer's *History of the Jewish People in the Time of Christ* (Eng. trans. 2d div. vol. iii. Edin. 1886).

**Enos** (the ancient *Enos*), a seaport of the Turkish province of Adrianople, on a rocky isthmus near the mouth of the Maritza, about 35 miles NW. of Gallipoli. It has some trade in wool, cotton, leather, wax, &c., but its harbour is now very shallow and choked up with sand. Pop. 8000, principally Greeks.

**Enriquez Gomez**, ANTONIO (properly ENRIQUEZ DE PAZ), a Spanish poet, the son of a baptised Portuguese Jew, was born at Segovia early in the 17th century. He entered the army in his twentieth year, and rose to the rank of captain; but in 1638 fled to Amsterdam, and, having there professed the Jewish faith, was in 1660 burned in effigy at a Seville auto-da-fé. The date of his death is not known. For his twenty-two comedies, of which some passed as Calderon's, and his poems, see Tiecknor's *History of Spanish Literature*.

**Ensche'de**, a town of Holland in the province of Overijssel, 30 miles ENE. of Zutphen. Rebuilt since its destruction by fire in 1802, it has large yarn and cotton mills. Pop. 5664.

**Ensign** was, until 1871, the title given to officers of the lowest commissioned rank in the British infantry (the corresponding rank in the cavalry being Cornet), because they carried the regimental Colours (q.v.) or ensign. Formerly this was a duty attended with much danger when in action, and considered highly honourable; but colours are no longer taken into battle, and officers of the rank of ensigns and cornets are now called sub-lieutenants.

ENSGN is also the name of the distinguishing flag on board ship. See FLAG.

**Ensilage.** See SILAGE.

**Enstatite**, an important rock-forming mineral. It is essentially an anhydrous silicate of magnesia, but usually contains also small percentages of alumina and ferrous oxide. It belongs to the pyroxene group of minerals.

**Entablature**, that part of a design in classic architecture which surmounts the Columns (q.v.), and rests upon the capitals. It is usually about two diameters of the column in height, and is divided in every style of classical architecture into three parts—architrave, frieze, and cornice. These parts vary in their relative proportions in different styles. In Doric architecture, for example, if the entablature be divided into eight equal parts, two of these form the height of the architrave, three that of the frieze, and three that of the cornice. In the other styles, the relative proportions are as three, three, and four.

Fig. 1.—Example of Doric Entablature.

The *Architrave* is the horizontal portion which rests immediately upon the abacus of the column. It is usually ornamented with horizontal mouldings, with flat spaces or *fasciæ* between. The upper moulding always projects farther than the others, so as to throw off the rain. This moulding varies in different styles. In Doric (fig. 1) it is a plain square projection, with small pendants or *guttae* under the triglyphs. In the other styles it is generally an ogee or talon moulding. These mouldings are frequently enriched with leaf ornaments, and in very florid designs the *fasciæ* are also enriched.

The *Frieze* is the middle portion of the entablature, between the top of the architrave and the bed of the cornice. In the Doric style it is ornamented with triglyphs or slight projections, divided by angular grooves into three parts. The spaces between the triglyphs (called metopes) are square, and are either plain or enriched, either with figure-sculpture, as in the Parthenon, or with bulls' heads, pateræ, or other ornaments. In the other styles the frieze is never cut into portions, but is either left quite plain or ornamented with figure-sculpture or scroll-work. The former is most usual in Greek art, the latter in Roman. In late Roman works the frieze is sometimes *swelled* or made to project with a curve.

The *Cornice* forms the upper portion of the entablature. It is divided into several parts. The lower moulding or mouldings resting on the frieze are called the bed-mouldings, the lower member of the upper projecting part is called the Corona (q.v.), and between the two there are frequently introduced

modillions and dentil bands. The bed-moulding is generally of an oval or cecilius form, and is frequently enriched with the egg and tongue or leaf ornaments. The upper moulding of the corona is generally of a *cyma recta* form (see COLUMN, fig. 1), and is often ornamented with lions' heads. These represent the openings through which the rain was at first led off from the roof-gutters cut in the top of this moulding, and were retained as ornaments after their original use was discontinued. The corona projects well over the frieze and architrave, and protects them from rain, while at the same time, by its broad shadow, it gives repose and variety of effect to the building. The *soffit*, or under side of the corona, is frequently panelled and ornamented with pateræ.

*Origin.*—The component parts of the entablature are said, with some appearance of truth, to owe their origin to the forms of the construction of the oldest temples. These were of wood, and were put together in the manner most natural for that material. The square beams laid across from post to post are represented by the architrave; the triglyphs of the frieze are copied from the ends of the cross-beams; the cornice is taken from the boarding which covered the rafters and ties of the roof—projected so as to throw off the rain; and the dentils and modillions show the ends of the rafters left uncovered. It is not supposed that these features were intentionally imitated by the classic architects, but that the original wooden construction produced forms which were afterwards traditionally though unconsciously followed.

Whatever the origin of the entablature may have been, it is a remarkable fact, as connected with Greek and Roman art, how persistent the entablature was as a feature in the decoration of all classic styles. So long as buildings consisted of one story in height, this was quite natural; but after this simple system was abandoned, and when, as in Roman architecture, several series of columns and entablatures were piled one above the other—not used constructionally, but simply applied to the face of the building—the cornice, frieze, and architrave still retained their places and proportions. In the revived Roman art of the 16th century the entablature was used in a manner still further removed from its original purpose (fig. 2).

Fig. 2.—Example of Composite Entablature.

The strict proportions of the various parts were entirely lost sight of. The frieze was increased in height, so as to admit of small windows, to light the Entresol (q.v.) or mezzanine, and in the French and English forms of the Renaissance the various members become still more attenuated and altered from the original design (see RENAISSANCE). But in no modification of classic

architecture, however debased, is the entablature wanting. The architrave, frieze, and cornice are essential portions of every classic design.

**Entada**, a genus of leguminous climbing shrubs (sub-order Mimoseæ) remarkable for their great pods. The egg-sized seeds of *E. gigalobium* are carried by the Gulf Stream not only to the Canaries, but to Nova Zembla, where their occurrence suggested the name of 'Chestnut Bay.'

**Entail.** The desire to preserve in our own family land which we have either inherited or acquired appears to be inherent in the human mind. Arrangements of this nature were not known to primitive peoples, among whom land descended according to strict customary rules which could not be altered by the act of an individual owner. In some of the ancient Greek states owners of property were permitted to name successors to their estates, and to appoint a substitute who should take the estate on the failure of him first named. The substitute so appointed was permitted to succeed on the death of the institute (as he was called) without leaving issue or without alienating the estate. Under the Roman law the practice of settling land upon a series of heirs, by means of *Fideicommissa* (q.v.), grew up, and was sanctioned by the state. These deeds, in their early form, contained merely a substitution of heirs. But by the later law a much fuller form of settlement was admitted, whereby the estate was protected from every sort of alienation. The limitation to a particular line of descent, the prohibition to alienate or burden with debt, and the still more peculiar feature of the declaration of forfeiture in case of non-compliance are to be found in both forms. There are, however, two points in which the Roman law differed from modern laws of entail. It did not recognise the right of Primogeniture (q.v.), and after the legislation of Justinian the limitation of the deed was restricted to four generations. For the right of primogeniture, as recognised in deeds of entail, we are indebted to the feudal law. That system, which has united with the civil law to form a basis for the codes of modern Europe, did not, in its original form, recognise the right of a holder of land to alienate his feudal benefice, or even to alter the succession, because on the failure of heirs the fief returned to the superior. But the right of the eldest son to represent his father, both in the duties and privileges of the fief, if not an original principle of the system, was universally recognised in the days of its greatest power.

In *England*, the Saxons seem to have prohibited the alienation of lands by those who had succeeded to them under condition that they should not alienate. The law of primogeniture was not recognised. But after the Norman Conquest feudal grants were often made 'to A and the heirs of his body,' or 'to A and his heirs, if he shall have heirs of his body.' The estate thus given was regarded as a fee-simple conditional; on the birth of an heir of his body, A would acquire the fee; and, like other owners in fee after the 13th century, he was at liberty to alienate. To prevent this, the feudal lords obtained the enactment of the statute *De Donis*, by which it was directed that the fee given with the words above quoted should in all cases descend according to the form of the gift; so that, in the case supposed, A would not have a fee-simple, an estate to him and his heirs-general, which he was free to alienate, but a fee-tail—i.e. a fee *taillé* or cut down, which he could not alienate so as to bar the rights of his issue. Under the statute, lands might be settled in tail, or in tail male, or in tail special—i.e. on a man and the heirs of his body by a particular wife.

A settlement in tail special was somewhat analogous to a settlement in Frankmarriage (q.v.).

The restraints on alienation thus imposed were contrary to sound policy, and the courts permitted tenants in tail to bar or cut off the entail; a tenant in possession was permitted to bar all rights of other persons, and so to turn his own estate into a fee-simple. From the time of Edward IV. down to 1833 this was effected by means of fictitious actions, called Fines and Recoveries; for these cumbersome and expensive forms the 3 and 4 Will. IV. chap. 74 substitutes a simple disentailing deed. A strict settlement of land usually begins with an estate for life to an existing person, followed by an estate tail to his son. When the donee of the estate tail comes into possession, he can disentail and alienate at his own discretion. If not in possession, he can dispose of his own rights and those of his issue; but he cannot destroy the entail, so as to bar remaindermen and reversioners, and turn his estate into a fee-simple, unless with the consent of the 'protector of the settlement,' who is usually the tenant for life. An estate tail is a freehold of a limited description. Tenant in tail in possession may commit Waste (q.v.). Formerly, an estate tail was not liable to the debts of the tenant, but by 1 and 2 Vict. chap. 110 this restriction has been removed. Copyhold lands have been held not to fall under the operation of the statute *De Donis*. A limitation, therefore, which in a freehold creates an estate tail, in copyhold lands creates a fee-simple conditional, according to the old common law, except where the custom of the manor is to the contrary. But, by trust-conveyances, copyhold estates may be settled in the same way as freeholds. The rules against Perpetuities (q.v.) prevent property from being tied up for an indefinite period; but family estates are usually re-settled by owners and heirs of entail in each generation. Lord Cairns's Settled Land Act, 1882, has given to tenants for life absolute power of sale upon notice to the trustees of the settlement, and without petition to the court, the price being invested for the persons interested under the settlement. By a series of statutes in England, tenants for life have also received large powers of managing and improving their estates.

In *Scotland*, as in England, entails appear first to have taken their rise from the feudal usages, and from the Roman law, the forms of which were closely followed by conveyancers. It has been observed by Lord Kames that, while the feudal system was in its vigour, every estate was in fact entailed, because no proprietor had any power to alter the order of the succession. But when the stricter feudal principles gave way, and the power of alienating land began to be recognised, the holders of estates sought by deed to secure in their own families the lands which they possessed. The form first adopted for this purpose was the simple destination, whereby the estate was simply limited to a particular series of heirs, without prohibition to alienate, or declaration of forfeiture for contravention of the will of the grantor. In this form the deed must have resembled the early English entails. The feudal law of primogeniture having been received as a principle of common law, the estate would naturally descend from father to son in the line indicated by the deed. But, as it was held that those succeeding under this deed were not restrained from alienating, the practice of adding prohibitory clauses was introduced. Entails in this form were held to bind the heir from granting gratuitous alienations; but he was not restrained from selling the estate, or burdening it with debt. Early in the 17th century a further addition was made to the form of the deed by the introduction of irritant and resolute

clauses—i.e. clauses declaring the act of alienation to be null, and to infer the forfeiture of the estate. The form thus adopted, which resembles closely the form of the Roman deed already noticed, was fortified by a decision of the Court of Session on the Stormonth entail in 1662, holding that an estate so protected could not be attached by creditors. This decision created much difference of opinion amongst lawyers as to the power of the grantor thus to protect an estate from the onerous act of the heir. In consequence the famous Scotch Entail Act, 1685, chap. 22, was passed, by which it was enacted that an estate conveyed by a deed fortified by prohibitory, irritant, and resolute clauses, and recorded in a particular register, should be effectually secured in the line of destination. This act has always been most strictly viewed by Scottish lawyers; and entails which have been found deficient in any of the prescribed requisites have been regarded by the courts as utterly ineffectual. The operation of the old entail act was found, notwithstanding, to be of the most oppressive character. Statutes were in consequence passed from time to time, empowering heirs of entail to exercise larger powers of ownership than could be granted under the Act of 1685, and to make provisions for their families. Chief among these were the Montgomery, the Aberdeen, and the Rosebery Acts. At length, by 11 and 12 Viet. chap. 36 (known as the Rutherfurd Act), the power of tettering lands by a strict entail has been finally destroyed. By this act, heirs under an existing entail may disentail, with the consent of certain heirs next in succession; and in all entails made after 1st August 1848, and also in old entails where the heir in possession was born since 1st August 1848, the heir of entail in possession may, by means of a simple deed of disentail, free his estate from the restrictions of the entail. A statute in 1875 gave the heir in possession larger powers of permanent improvement and the right of buying out the interest of the next heirs at a compulsory valuation; and the Entail (Scotland) Act, 1882, gave further powers of disentailing in the case of entails made since 1848, and in all cases a practically absolute power of sale to be exercised on petition to the court, the price being invested for behoof of the heirs of entail. From statistics returned to parliament in 1882, it appeared that disentailed land was rapidly re-entailed in Scotland.

In *America*, before the Revolution, the English law as to estates tail prevailed. But in the United States, the law of entails has been gradually abandoned by the several states; and property can now be fettered to a limited extent only, by means of executory Devises (see WILL). In *Germany*, family settlements of a very strict character, and 'private laws' regulating the descent of property in certain noble houses, are permitted by the laws of some of the states which form the German empire. In *France*, the power of creating entails has varied much at different periods, from the right to make a perpetual entail, which appears to have been the original principle, to a limitation to four, and at one time to two degrees. But by the Code Napoléon, arts. 896-897, entails are now absolutely prohibited. In *Spain*, also, entails, till then permitted under certain restrictions, were entirely abolished by the Cortes in 1820. Thus it will be seen that the right of securing land in a particular family, which commends itself to the natural feelings, has been found so oppressive in operation, and so injurious to the public interest, that, after an existence of more than 600 years, it has been practically discarded almost simultaneously by the general consent of modern nations.

See Williams's *Principles of the Law of Real Property*; Sandford's *History and Law of Entail in Scotland*; Reports by H.M. Consuls on *Systems of Land Tenure* (1870); and Cobden Club *Essays* on the same subject.

**Entellus Monkey**, or HANUMÂN (*Semnopithecus Entellus*), the most sacred monkey of the Hindus, worshipped as half divine, and regarded as the host of ancestral souls. The body is 4½ feet in length, from ash-gray to dirty yellow in colour; the face is dark, with bushy grayish-white whiskers; and the tail is longer than the body. Entellus

Entellus Monkey (*Semnopithecus Entellus*).

monkeys live in troops, are noisy and quarrelsome, and do much mischief near towns and plantations, but are nevertheless revered and petted. Their home is in the 'hot tropical plains of the north-western Gangetic provinces,' but they have been introduced elsewhere. They are sometimes confused with the Langoor, and probably with others. For the mythology, see HANUMÂN.

**Entente Cordiale** (Fr., 'cordial understanding'), a term which originated, according to Littré, in the French chamber of deputies in 1840-41, and which has been used especially to denote the friendly relations and disposition existing between France and Great Britain.

**Enteric Fever.** See TYPHOID FEVER.

**Enteritis** (Gr. *enteron*, 'an intestine'), inflammation of the bowels. Under this name are grouped cases of every possible degree of severity. In the slighter forms the symptoms are, generally speaking, lassitude, loss of appetite, foul tongue, vomiting (if the upper part of the intestine be affected), griping pains, diarrhoea (if the lower part be involved). Such cases are very rarely dangerous, except in young children; for their treatment the measures recommended under Diarrhoea are usually effective. The severer forms of the disease usually depend either on external injury or on internal mechanical causes. It is often associated with Peritonitis (q.v.). The treatment must depend on an accurate diagnosis, often a matter of extreme difficulty. The symptoms are pain, tenderness, fever, prostration; generally obstinate vomiting with constipation, owing to paralysis of the portion of gut affected; and rapid failure of strength, without delirium or insensibility. If enteritis does not arise from mechanical obstruction, it may be combated by hot fomentations, with moderate leeching and counter-irritation, and the internal administration of opium. Injections of warm water, or of asafoetida and turpentine (see CLYSTER), should be at the same time given to clear the lower bowel; and all purgatives, except in some cases castor-oil, should be avoided. The disease is, however, one of great danger, often rapidly fatal, and should never be incautiously treated with domestic remedies.

*In the Lower Animals.*—Among horses, inflam-

mation of the bowels generally results from some error of diet, such as a long fast followed by a large, hastily devoured meal, such as raw potatoes, boiled or indigestible and easily fermentable food, or large draughts of water at improper times. When thus produced, it is frequently preceded by colic, affects chiefly the mucous coat of the large intestines, and often runs its course in from eight to twelve hours. With increasing fever and restlessness, the pulse soon rises to 90 or upwards, and, unlike what obtains in colic, continues throughout considerably above the natural standard of 40 beats per minute. The pain is great, but the animal, unless delirious, instead of recklessly throwing himself about, as in colic, gets up and lies down cautiously. Respiration is quickened, the bowels torpid. Cold sweats, stupor, and occasionally delirium, precede death. When connected with, or occurring as a sequel to influenza, laminitis, and other complaints, the small intestines are as much affected as the large, and the peritoneal as well as the mucous coat of the bowels. When the animal is seen early, whilst the pulse is still clear and distinct, and not above 70°, and the legs and ears warm, bloodletting is useful, as it relieves the overloaded vessels, and prevents that extravasation of blood which speedily becomes poured out in the interior of the bowels. This disease should be treated as follows: Care should be taken not to further irritate the bowels by the administration of purgative or even aperient medicines, as the supposed constipation is due to the bowels having lost their function—loss of function being one of the phenomena of inflammation—and not to a dry condition of their contents. Anodynes and sedatives, as laudanum in two-ounce doses, or belladonna extract in two or three drachm doses, should be repeated every two hours until pain is relieved. Morphia and atropia subcutaneously injected are also now largely used by veterinarians with fomentations to the surface of the abdomen and an occasional clyster of warm water. No attempt should be made to force the bowels to action after apparent recovery, or the inflammation may be re-excited.

Enteritis in cattle is mostly produced by coarse wet pasture, aerid or poisonous plants, bad water, and overdriving. The symptoms are fever and thirst, a quick but rather weak pulse, restless twitling up of the hind limbs, tenderness of the belly, moaning and grinding of the teeth, and torpidity of the bowels. Calves generally die in three or four days, other cattle in a week or nine days. Enteritis in sheep mostly occurs in cold, exposed localities, and where flocks are subjected to great privations or improper feeding. The symptoms and treatment resemble those of cattle. The treatment prescribed for the horse is applicable to the cow, the doses being one-third larger.

**Enteropneusta**, a class of worm-like animals, including *Balanoglossus* (q.v.) and *Cephalodiscus* (q.v.). It is of great zoological importance because of the characters in which the members resemble vertebrates. The name, literally 'gut-breathers,' refers to the paired respiratory pouches opening from the front part of the alimentary canal.

**Entomology** (Gr. *entomon*, 'an insect,' *logos*, 'a discourse'), the study of Insects (q.v.).

**Entomostraca**, a general name for the lower orders of Crustacea, including Phyllopoets, Ostracods, Copepods, and Cirripedes. See CRUSTACEA.

**Entophytes**. See PARASITISM; also PLANTS (DISEASES OF), FUNGI.

**Entozoa**, internal parasites such as Tapeworms (q.v.). See PARASITISM.

**EntRACTe**, in Music, is an instrumental piece, composed in the form of a short symphony or overture, to be performed between the acts of a play.

**Entrecasteaux**. See D'ENTRECASTEAUX.

**Entre Douro e Minho**, or, as it is frequently called, MINHO, a province of Portugal, in the extreme north-west of the country, is bounded on the N. by the river Minho, and on the S. by the river Douro. Area, 2810 sq. m.; pop. (1881) 1,014,768. It has been called the Paradise of Portugal. The climate is agreeable and healthy. The chief productions are wine, oil, flax, maize, wheat, barley, oats, and vegetables. Wine is shipped largely at Oporto, the capital. Along the coast are numerous fisheries, at which great numbers find employment. The province of Minho consists of three districts, Braga, Vianna, and Oporto.

**Entrenchments** are the earthen parapets thrown up to give cover against the enemy's fire, and the ditches or trenches from which the earth is obtained for them. They may be either of the most hasty or of the most deliberate kind. Of the former class are the various patterns of shelter-trench, in which the men stand, kneel, or lie in the trench 1 foot 6 inches to 3 feet deep, and fire over a parapet 1 foot 6 inches to 2 feet 9 inches above the ground-level, and also the different saps used for siege purposes, in which the trench forms the roadway towards the fortress attacked, and the parapet gives cover to the troops using it. The deliberate kind include all field and permanent works, having a thick parapet of considerable height, over which the men fire, and by which they are protected, while the ditch from which the earth for the parapet has been dug forms an obstacle in its front (see FORTIFICATION). The term is also used for any fence, building, wood, or other natural cover that has been scientifically prepared for defence.

**Entre Rios** ('between rivers'), a province of the Argentine Republic, in the 'Mesopotamia Argentina,' between the Paraná and the Uruguay (whence its name). Estimated area, 29,021 sq. m., or a little larger than Portugal; pop. (1886) 180,000. The country is chiefly pastoral, but in 1888 there were 326,000 acres under cultivation, 260,000 being devoted to maize and wheat. The province is fertile and well watered, being even subject, in the south, to annual floods; nevertheless, the climate is very healthy. Lime and gypsum are worked. In 1887 the province had 233 miles of railway. The capital is Paraná (q.v.).

**Entresol** is a low story between two main stories of a building, generally above the first story, but in London most usually between the ground-floor and the first story. *Mezzanine* is another name for the entresol, as also for its low, broad windows.

**Entropium**, or ENTROPION (Gr. *en*, 'in,' and *trepō*, 'I turn'), inversion of the edge of the eyelid, consequent either on loss of substance on its inner surface, or on excessive action of the muscle (the orbicularis palpebrarum) which closes the lids. The eyelashes are turned inwards and rub upon the globe during the movements of the lids, producing much irritation, and sometimes opacity of the cornea. Temporary relief may be obtained by plucking out the misdirected lashes by the roots;

a, Entresol.

but the radical cure of severe entropion requires a careful adaptation of the surgeon's art to the circumstances of the particular case, and should not be attempted by unskilled hands. The most common cause of entropion is granular conjunctivitis. See EYE (DISEASES OF).

**Entry, FORCIBLE.** See FORCIBLE ENTRY.

**Envelopes.** Until the introduction of the penny-postage system, envelopes for written letters were very little adopted; it was far more customary to secure by wafer or sealing-wax the folded sheet of paper on which the letter was written. When the postage was rendered uniform for all distances, and prepayment enforced, or at least recommended, it was supposed that stamped envelopes would be convenient coverings for letters, sealing the letter and paying the postage at one operation. These, however, were soon found to be inconvenient, and the great development of envelope manufacture has taken place in the direction of unstamped varieties of envelopes, to which, of course, adhesive stamps can be attached. During the last half-century this development has taken place to an extent that no one could have contemplated. Several large firms in England and Scotland, as well as abroad, are engaged in it, and the quantity of envelopes turned out is simply enormous; the largest producers being Messrs Pirie of Aberdeen, whose turn-out amounts to upwards of thirteen millions per week.

In the manufacture of envelopes, the web of paper is first cut by machine-power, sometimes into rectangular, but more commonly into lozenge or diamond-shaped sheets of large dimensions. These sheets are then placed in convenient piles, and each pile is placed under a series of dies, which are pressed by steam-power down through the pile, thus cutting out a number of very much smaller sheets, termed 'blanks,' of the exact shape of the required envelope, when unfolded and spread out flat. The next process is that of folding and gumming, which is done by hand, or by machine, but chiefly by the latter. In hand-folding, girls fold with wonderful rapidity, having guides to aid them in folding at the proper place; and the gum is applied to the various parts with a small brush. This process is, however, so very slow that it has now been almost superseded by machine folding and gumming. In machine-folding the process is as follows: The blanks are placed in a pile on the front part of the machine, which is self-feeding; the machine being set in motion, the automatic feeder comes forward, and, in lifting the blank, gums the bottom flap, at the same time gumming the upper or open flap, and deposits the blank in an open frame. A plunger descends and forces the blank through the frame to a door. Folders press down the four flaps, fastening the lower one only, the door is lowered, and the envelope is by this action dropped into an endless chain, where it is held in position by means of pins. The envelope then passes through a drying process, and comes out at the other end of the machine ready to be packed up and despatched. The quantity of envelopes that can be made on such a machine is ninety per minute. Where twelve of these machines are working at once, it will be seen that a million envelopes are put out of hand in a very short time. Nearly a million and a half of enveloped letters pass through the post every day in the United Kingdom, most of the envelopes for which are of home manufacture; and besides this, a large export trade is maintained. The stamped envelopes all go to Somerset House, to have the stamp impressed upon them, which is done by a beautiful machine, chiefly invented by Mr Edwin Hill, in which embossing and colour-printing are ingeniously com-

bined. These envelopes are sold by the Stamp-office, between which and the Post-office a monetary adjustment becomes necessary.

**Environment,** a modern term for the influencing surroundings of an organism. Neither plant nor animal can be understood as a rounded-off unity; the whole life or function is made up of action and reaction between the organism and its environment. Streams of matter and energy from without preserve the relative constancy of the organism, as of a special wave-crest in the sea; while changes in the streams have their corresponding changes within. The plant or animal has obviously a strong unity of its own, but even that is in part due to ancestral welding under the hammers of the environment. It may seem, too, to vary of itself like a fountain in the air, but throughout all its rises and falls there blows the wind of the environment. The influence of outside conditions has been recognised by most naturalists from the time of Hippocrates, and is taken for granted in our everyday speech and action. There is considerable difference of opinion, however, as to the importance and degree of this influence. Thus Buffon, Treviranus, and Geoffroy St Hilaire regarded the surroundings as *directly* hammering changes on the organism; while to Erasmus Darwin and Lamarck internal changes arose as *indirect* functional results of new environment. Charles Darwin allowed a measure of truth in both these positions, but emphasised the indirect destructive action of the animate and inanimate environment in the struggle for existence. These three positions are still held, some emphasising one, others another, the majority combining the three (see EVOLUTION).

The external influences may be classified in four groups: (1) Molar or Mechanical; (2) Chemical; (3) Molecular or Physical; (4) Vital or Animate. A few instances of each kind of influence will be given; for details, the reader must be referred to Semper's *Animal Life*, and an appendix paper to that classic work.

(1) *Molar or Mechanical Influences.*—Confined space brings about a dwarfed brood. Currents mould the sponges and corals, chisel the shells, cut up the water leaves; and the wind blows the trees out of shape. Vertical pressure may broaden out the form or produce latent life; while the very weight of structures effects many changes, from the mode of an egg's dividing to the slope of a tree's branches. On the whole, however, the mechanical hammers effect least.

(2) *Chemical Influences.*—Subtler but more potent are the influences which we group together as chemical. Good aeration—i.e. abundant oxygen—quickens development and stimulates the whole life. The 'vital combustion' is more rapid. In drought some animals become desiccated (see DESICCATION), and the Axolotl (q.v.), removed from the watery bed into less moist environment, becomes an Amblystoma. The composition of the medium seems to have a great influence on the forms and phases of simple unicellular life, and even a comparatively high animal like the Brine-shrimp (q.v.) was converted by Schmankevitsh from one species into another by gradually altering the salinity of the water. Food may be included under this group, and its influences are the greatest. To Claude Bernard the whole problem of evolution was very much a question of variations in nutrition. It is the food, to a large extent, which conditions the cyclic changes in cell-life from an active ciliated phase to a passive amoeboid or encysted one (see CELL). Parasites in their passivity illustrate a nemesis at least exaggerated by their copious nutrition. Abundant food is associated with growth and asexual multiplication; the plant

sends out its runners, the plant-lice continue their rapid parthenogenesis (see APHIDES), but a check to nutrition hastens the sexual climax. Good nutrition tends towards the production of female offspring; by increasing the quantity and quality of food Yung nearly doubled the normal percentage of females among his tadpoles; while starved caterpillars and tadpoles tend to turn out mostly males. According to Sutton, hypertrophy of one part over another has been the principal process in the transition from hermaphroditism to unisexuality, while Barfurth emphasises the importance of fasting as a progressive factor in evolution. From the cell-cycle to the colour of canaries' feathers, the importance of the food-factor is widely demonstrable.

(3) *Physical Influences*.—Heat stimulates growth and hastens the reproductive maturity, while cold tends to dwarf and often produces coma. Maupas increased the rate of reproduction in an Infusorian five times by an elevation of 17° C. in the temperature of the water. Dallingier has recently described how the monads which he succeeded in educating to stand a temperature high above the usual fatal point became not a little altered at the crisis of each successive elevation. Weismann has shown how an artificial winter induces the winter colouring of a certain Butterfly (q.v.). The sunlight which kills the floating germs has a beneficent action on most organisms, very notably on plants. In some cases it seems to affect colour, and Poulton has altered the colour of his Caterpillars (q.v.) by the tint of the glass under which they lived, or has produced golden chrysalids by keeping them in gilded boxes. Electric and probably magnetic energies seem to have influences, but these cannot yet be said to be intelligible.

(4) *Vital Influences*.—In the web of life organisms influence one another indirectly in a hundred ways, but they have likewise their direct influences. There are animate as well as inanimate 'hammers.' Sea-spiders specifically alter Hydroids, and Semper also notes the mutually influencing associations of a snail and a coral, of an Annelid and an Antipathes (a genus of Zoantharia). Crustacean parasites may very effectively alter their crustacean hosts, and internal guests have also marked results. Nor have insects worked about plants for millennia without leaving direct mechanical imprints of their footsteps. Finally, man's influence in Domestication (q.v.) may be mentioned.

Hundreds of cases of external influence, now on one system, now on another, are known, but few are thoroughly understood. The observation of the results is one thing, their rationale another. In a general way, barring purely mechanical modifications, the influences are referable to two classes—one set increasing constructive processes, storage of energy, passivity, anabolism; the other set increasing destructive processes, expenditure of energy, activity, katabolism.

The susceptibility of organisms to outside influences is very varied. Simple and young forms are evidently more in the grip of external circumstances than are complex and adult organisms. The cell, the seedling, the child, are more impressible than the worm, the tree, the man. Passive forms also, like sponges and algae, corals and trees, are much more under the tyranny of surroundings than active organisms with devices at command for parry or escape. The vegetative system, again, is oftener affected than the reproductive, and thus doubtless many environmental influences affect only the individual 'body,' and are not transmitted to the species.

The degrees of influence are also very varied. The dints of the environment may be deep or superficial, very direct or very remote in their results. A primary influence from without may have more

than one result within the organism, by starting correlated variations. The influence may remain without apparent result in the individual, and yet the nemesis may be evident in the offspring. Influences may also accumulate within the organism without any evident outcrop for a time, but at length an indirect, at first slight spontaneous, change may be the far-off result. The influence of environment in forcible distribution, in a cataclysmic destruction of local fauna, and the countless indirect results of changed conditions must also be kept in view.

The action of the environment as a factor in organic evolution is very variously estimated by different schools of naturalists (see EVOLUTION). It is still undecided how far characteristics impressed upon an individual organism by outside forces can be transmitted. If the influence send its roots deep into the organism, it may probably affect the reproductive elements, and thus become transmissible; but according to Weismann and others, no facts demonstrating such cases are as yet known. It must not be forgotten, however, that no organs of the body are really insulated, and that changes from without may be transmitted by infinitesimal degrees for each individual generation, till they eventually, if the conditions remain constant, accumulate into a specific character. In opposition to Weismann's view, Professor G. H. T. Eimer's work (1888) on the *Origin of Species*, as based on the inheritance of acquired characters according to the laws of organic growth, should be consulted (see HEREDITY).

Finally, as there is no doubt as to the importance of environmental conditions for at least the individual organism, the influence of human environment must be recognised as a biological fact of the greatest social moment.

See Semper's classic work, *The Natural Conditions of Existence as they affect Animal Life* (Inter. Sc. Series, 1880); G. H. T. Eimer, *Die Entstehung der Arten* (1888); J. Arthur Thomson, 'Synthetic Summary of the Influence of the Environment upon the Organism,' *Proc. Roy. Phys. Soc. Edin.* ix. (1888), pp. 446-99.

**Envoy**, a diplomatic minister of the second order—i.e. inferior in rank to an ambassador. Like the latter, he receives his credentials immediately from the sovereign, though he represents not his prince's personal dignity, but only his affairs. The envoy is thus superior in rank to the Chargé d'Affaires (q.v.). See also AMBASSADOR, and CONSUL.

**Eocene System**, in Geology. This is the lowest or oldest series of strata included in the Tertiary division. The name Eocene (*eos*, 'dawn,' *kainos*, 'recent') was introduced in 1830 by Lyell, whose classification of the Tertiary formations was based on the proportions of living species of molluscs which the strata contain. The oldest members of the series, containing as they do only an extremely small proportion of such recent forms (according to Lyell, 3½ per cent.), were looked upon as indicating the dawn of the existing state of the molluscan fauna. With necessary modifications, Lyell's classification has maintained its place, but the names of the various subdivisions of the Tertiary strata, first suggested by an examination of the European deposits, are now used without reference to the precise percentage of living molluscan species which the beds may chance to contain. The Eocene beds rest unconformably upon the Chalk or Cretaceous strata—hence there is a break in the succession. A movement of elevation followed upon the close of the Cretaceous period, and the sea disappeared from middle Europe. Probably the British area at this time was connected with what are now the opposite coasts of the Low Countries and

France, and considerable denudation of the later Cretaceous deposits supervened. Ere long, however, partial subsidence set in, and at the beginning of Eocene times the sea commenced to invade those regions in the south-east of England, the north of France, and the low grounds of Belgium, in which we meet with the oldest accumulations of Tertiary times.

The Eocene system, as developed in England, occurs chiefly in two districts, called respectively the London and Hampshire basins. In the north of France it forms another large basin, in the centre of which is Paris, and it likewise spreads over a considerable area in Belgium. The strata are partly of fresh-water and partly of marine and brackish-water origin, and consist principally of more or less unconsolidated sands, clays, loams, marls, &c., with which are here and there interstratified layers of limestone and lignite. Grouping the Anglo-French and Belgian strata together, we have the following succession:

		FRANCE AND BELGIUM.	
UPPER EOCENE.	Barton Clay and Upper Bag-shot Sands.....	Gyps marin: Sables moyens.—Wemmelman.	
	Blackesham Beds.....	Calcaire grossier.—Lackmann: Bruxellian.	
	Middle Bagshot Sands.....	Waiting in France: Pansellian, Upper Ypresian.	
	Lower Bagshot Sands.....	Waiting in France — London Clay and Bognor Beds.....	Lower Ypresian
LOWER EOCENE.	Oldhaven Beds.....	Not recognised.	
	Woolwich and Reading Beds.....	Argile plastique: Lignites du Saisonais.—Upper Landenian.	
	Thanet Sands.....	Sables de Brecheux.—Lower Landenian and Heersian.	
	Waiting.....	Montian.	

In the south of Europe the Eocene system is developed on a much larger scale. In place of the limited basins of the Anglo-French and Belgian areas we encounter a thick and widespread series of limestones and calcareous sandstones. These accumulations appear on both sides of the Mediterranean, in Spain, and in Morocco. They enter largely into the composition of the Apennines, the Alps, the Carpathians, and the Balkans; they extend through Greece, Egypt, and Asia Minor, and thence through Persia and the Himalayas to the coasts of China and Japan. The most characteristic feature of these thick calcareous beds is the occurrence in prodigious numbers of nummulites—a foraminifer. Another noteworthy feature of the Eocene system of southern Europe is the occurrence in the Alpine region of Bavaria of certain sandstones, &c. (locally called *Ktyisch*), in which appear many gigantic erratics of various crystalline rocks—the precise source of which is not known. They may possibly have been derived from the archæan masses of Bohemia. In North America the more important Eocene strata are the great lacustrine deposits of the Rocky Mountain region and the plateaus lying to the west. But marine deposits of the same age occur also along the borders of the Atlantic, the Mexican Gulf, and the Pacific.

The flora of the Eocene is represented chiefly by dicotyledonous and monocotyledonous plants, and had a prevalent Indo-Australian character. Palms, screw-pines, cypresses, and various proteaceous plants grew in England in early Eocene times, and with these were associated species of custard apple, gourd, melon, oak, walnut, magnolia, &c. Amongst the forms of later Eocene times were species of gum-tree, nettle-tree, and banksia, fan-palms and screw-pines, aroids and cacti. Evergreens were represented by laurels, cypresses, and yews, while deciduous trees were represented by species of maple, plane, willow, poplar, elm, beech, chestnut, hornbeam, walnut, fig, &c. The fauna, like the flora, is also indicative of somewhat tropical con-

ditions. Among the characteristic molluscs were species of *Conus*, *Voluta*, *Cyprea*, *Oliva*, *Nautilus*, &c. Sharks were numerous, such as *Otodus*, *Lamna*, and *Carcharodon*; and reptiles were represented by turtles, terrapins, snakes, lizards, crocodiles, and alligators. None of the great Mesozoic Saurians, however, survived into Tertiary times. Among the more remarkable birds were *Odontopteryx*, the jaws of which had tooth-like denticulations, and *Dasornis*, akin apparently to the extinct gigantic *Dinornis* of New Zealand. Early forms of modern types were also present, such as species of heron, gull, vulture, buzzard, woodcock, quail, pelican, flamingo, ibis, &c. Many of the mammals of Eocene times were remarkable for the union of characters intermediate between marsupials and carnivores. Tapir-like animals, such as *Palæotherium*, seem to have abounded. Another common form was *Anchitherium*, which had affinities to the *Palæotheres* and true horses. There were also many hog-like animals with intermediate or generalised characters, as well as transitional hornless forms of deer and antelopes. From the Eocene also came the earliest of the Prosimiæ—the lemur-like *Canopithecus*, as well as ancestral forms of bats, hedgehogs, and squirrels. From the American Eocene lacustrine beds have been obtained remains of some very remarkable types. Among these are four-toed and five-toed ancestors of the horse, and *Dinoceras*, an animal as large as the elephant, furnished with three pairs of horns and two long tusk-like canines (see *DINOCERATA*). Another strange order of animals (*Tillodonts*) combined characters which are now met with in such distinct groups as the ungulates, rodents, and carnivores.

The Eocene deposits of the Anglo-French and Belgian area appear to have accumulated in an inland sea opposite the mouths of one or more great rivers—the rivers evidently draining a continental land surface. In south Europe large areas which are now land were under water in Eocene times. The Mediterranean at that period extended considerably farther north and south than it now does, while eastwards it stretched into Asia, and seems to have communicated with the Indian Ocean. At this time the Pyrenees, the Alps, the Carpathians, and even the Himalayas were inconspicuous heights. Since the Nummulitic sea washed their base, they have been upheaved for thousands of feet—the old floor of that sea is now met with in the Alps at heights of over 10,000 feet, and in the Himalayas at an elevation of not less than 16,500 feet.

**Eolian Harp.** See *ÆOLIAN HARP*.

**Eolipile.** See *ÆOLIPILE*, *HERO*.

**Eon de Beaumont**, CHARLES GENEVIÈVE TIMOTHÉE D', known as the *Chevalier d'Eon*, was born at Tonnerre, in Burgundy, in 1728, studied law, and became an advocate. He attracted the notice of the Prince de Conti by some political writings; and in 1755 was introduced by the latter to Louis XV., who employed him in diplomatic missions to Russia and Austria. After serving a short time in the army, not without distinction, he was sent to London in 1762 as secretary of embassy, and shortly after was made minister plenipotentiary. On the death of Louis XV., the French ministry deemed it prudent to recall him, as they were afraid he might betray their secrets to the English government, which made him brilliant offers. After much negotiation, Eon consented to surrender certain compromising papers, and submit to the condition imposed by Louis XVI. of wearing feminine garb, which he had often before assumed as a disguise, and which he now wore till his death. The doubt as to his sex, fostered by his parents in his childhood, was maintained, for reasons which can only

be conjectured, till the end of his life. On the outbreak of the French Revolution, while he was again in London, he offered his services to the French nation, but nothing came of his offer. He maintained himself by giving lessons in fencing till in 1796 he was disabled by an accidental wound, after which he was reduced to great destitution. He died 21st May 1810, when an examination of his remains by a surgeon settled the question of his male sex, and put an end to the curiosity of the English public. His writings appeared at Amsterdam (1774) under the title of *Loisirs du Chevalier d'Eon*. The *Mémoires* which bear his name are not genuine. See Captain B. Telfer, *The Chevalier d'Eon de Beaumont* (1885), and the article 'D'Eon,' by Professor Laughton, in vol. xiv. of *Dict. Nat. Biog.* (1888).

**Eos.** See AURORA.

**Eosin.** See DYEING.

**Eötvös**, JOZSEF, Hungarian author, born 3d September 1813 at Buda, was educated at home by a tutor of republican sentiments, and studied philosophy and jurisprudence at the university of Pesth (1825-31). He became an advocate in 1833, but soon resolved to devote himself exclusively to literature, in which field he had already won a great reputation by two comedies and a tragedy. After his return from a journey abroad he published a work on prison reform (1838). This was followed (1838-41) by his great novel *Karthusi* ('The Carthusians'). He now began to distinguish himself in politics as a writer of incisive articles on the liberal side represented by Kossuth. *The Village Notary* (1846; Eng. trans. 1850) is marked by variety of incident, easy vigour of style, humour, and freshness. It was followed in 1843 by a powerful novel describing Hungary in 1514. When the revolution of 1848 broke out, Eötvös was for a time Minister of Public Instruction. In Munich he wrote a work (1854) on the influence of the ideas of the 19th century on the state and on society. In 1851 Eötvös returned to Hungary. In 1859 he published anonymously a notable book (in German) on the guarantees for the power and unity of Austria. In 1867 he was appointed Minister of Worship and Education; and he died at Pesth, 3d February 1871.

**Eozoön**, the name given in 1864 by Sir William Dawson to an assumed organism whose remains constitute reefs of rock in the Archean System (q.v.) in Canada; apparently a large foraminifer, which must have grown in sheets on the seabottom. Occurring as it does in rocks not formerly supposed to be fossiliferous, it would be the oldest known organism, and would deserve its name *Eozoön* ('Dawn-animalcule') *canadense*. The late Dr Carpenter strongly maintained the organic nature of Eozoön, but of late years the belief that it is inorganic has gained ground. Messrs King and Rowney were the first in Britain to express this belief. This is likewise the view held by mineralogists and petrologists generally. In 1878 Professor Mäbius subjected Eozoön to an exhaustive examination, and came to the same conclusion. He shows that the so-called 'proper-wall' or 'mammilline layer' of the supposed fossil consists simply of fibrous calcite. Under the microscope no 'delicate pores' or fine 'vertical tubes' appear in this fibrous band, but the fibres consist of minute four-sided needle-like prisms, lying close side by side.

**Epacridaceæ**, a small order of heath-like shrubs or small trees, usually indeed reckoned as the Australian sub-order of Ericaceæ, from which they are chiefly distinguished by the epipetalous stamens destitute of the peculiar specialisations of another dehiscence or appendages. Many species—e.g. *Epacris grandiflora*, &c., are cultivated in

our greenhouses along with the heaths proper. A few produce edible berries. See CRANBERRY.

**Epacts** (Gr., 'additions'), in Ecclesiastical Chronology, a set of nineteen numbers used for fixing the date of Easter and other church festivals, by indicating the age of the moon at the beginning of each civil year in the lunar Cycle (q.v.). At the reformation of the calendar in 1582 it was found that the Golden Numbers could no longer by themselves serve the purpose of adjusting the double reckoning by lunations and by the tropical or true year; and thus, instead of adopting the more rational computation, the Roman Church devised the artificial and involved method of epacts. The main point to determine is the age of the moon (in entire days) at the beginning of each civil year, or the number of days between the end of the ecclesiastical year in December and the 1st January succeeding. Thus, subtracting 354 days (12 lunations) from 365, we should have 11 days for the first annual epact, then 22 for the year following, then 3, 14, 25, 6, 17, 28, 9, 20, 1, 12, 23, 4, 15, 26, 7, 18, and 29; the series of 19 numbers being obtained in succession by adding 11, and when the sum exceeds 30, subtracting that number. This illustration, however, is simpler than any actual ease, by reason of the leap-years, which require 12 to be added for the following epact, and of the fact that no lunation is exactly 30 days long. When the lunar cycle of 19 years is completed, the epacts recur again in the same order. In the Anglican reckoning, as distinguished from the Roman, it is noteworthy that the Gregorian epact for any year is the same as the Julian epact for the year preceding, owing to the coincidence that 11, the number of days lost on the Julian account before our parliament adopted the reformed Calendar (q.v.), is also the number of days between the lunar and the solar years. The epact determines by subtraction the date of the first new moon in January; then by adding 29 and 30 alternately the successive new moons throughout the year are assigned to their respective dates. See Delambre's *Astronomie Moderne*, vol. i. 4-32.

**Epaminondas**, the most eminent of Theban generals and statesmen, and one of the noblest figures in Greek history, was born towards the end of the 5th century B.C. He was descended from an ancient but impoverished family, and led a retired life till his fortieth year, profiting by the instructions of Lysis the Pythagorean, an exile from Tarentum, who inspired him with enthusiasm for the elevated ideas which it was the object of his life to realise. Plutarch tells us that Epaminondas saved the life of Pelopidas in battle in 385, which was the beginning of one of the most famous friendships of antiquity. After the desperate but successful stratagem by which his fellow-citizens recovered the *Cadmeia* and expelled the Spartans (379), Epaminondas stepped forward immediately into the ranks of the patriots; and, when sent to Sparta in 371 to negotiate a peace between the two countries, displayed as much firmness and dignity as eloquence in the debate which ensued upon the question whether Thebes should ratify the treaty in the name of all Bœotia, the result of which ratification would have been equivalent to a recognition of her claim to supremacy over the Bœotian towns. To this the Lacedæmonians demurred, and the war was again resumed; Epaminondas was appointed to the chief command, and along with Pelopidas, with an army of but 6000 men, defeated twice that number of the enemy at Leuctra (371). Two years later, with Pelopidas, he marched into the Peloponnesus, and incited several of the allied tribes to fall away from Sparta. On his return to Thebes, Epaminondas

was accused of having violated the laws of his country by retaining the supreme power in his hands beyond the time appointed by law, but was acquitted in consequence of his open and animated defence. In the spring of 368 the war between Thebes and Sparta was renewed with increased fury, and Epaminondas made a second and somewhat unsuccessful invasion into the Peloponnesus, receiving on his return a check from Chabrias at Corinth. To atone for this unsuccessful undertaking he advanced with 33,000 men into Arcadia, and joined battle with the main body of the enemy near Mantinea, in the year 362 B.C. Epaminondas charged at the head of his men, and broke the Spartan phalanx, but was mortally wounded in the breast by a javelin. Being told by the physicians that he would die as soon as the weapon was extracted, he waited till he heard that the Boeotians had gained the victory, then drew out the javelin with his own hand, exclaiming: 'I have lived long enough.' See his Life by Cornelius Nepos, and, in German, Baueh (1834) and Poutow (1870).

**Epaulette** (from the French *épaule*) is a fringed shoulder-knot worn since 1793 by commissioned officers of the British navy, sub-lieutenants wearing one of gold lace, and other ranks two. Crowns, anchors, and stars worked in silver on the epaulette, and the size of the cords of the epaulette itself, indicate the degree of rank. Previous to the Crimean war officers of the British army wore gold epaulettes, and the men worsted ones. Many foreign nations still retain them for both naval and military officers.

**Épée**, CHARLES MICHEL, ABBÉ DE L', instructor of the deaf and dumb, was born at Versailles, 25th November 1712. Taking orders, he became a preacher and canon at Troyes, but eventually, on account of his Jansenist opinions, was deprived of this office, and now lived in retirement in Paris. In 1765 he first began to occupy himself with the education of two deaf and dumb sisters; and, as he asserts, without any previous knowledge of Pereira's efforts in the cause, invented a language of signs, by which persons thus afflicted might be enabled to hold intercourse with their fellow-creatures. His attempts being crowned with success, he determined to devote his life to the subject. At his own expense he founded an institution for the deaf and dumb, which was first publicly examined in 1771, and from 1778 received an annual subsidy. It was not, however, converted into a public institution till two years after his death, which took place 23d December 1789. He wrote two or three works on his system, for an estimate of which see Hartmann's *Deafmutism* (Eng. trans. 1881).

**Epeira**, a genus of spiders, the type of a family called Epeiridae, including the common Garden Spider (*Epeira diadema*). See SPIDER.

**Eperics** (Slovak *Pressova*), an old town of Hungary, on the Tarcza, 150 miles N.E. of Pesth by rail. It is the seat of a Greek Catholic bishop, and has a college, with 500 students. A conflagration of 7th May 1887 destroyed 400 houses and most of the chief public buildings. It manufactures earthenware, linens, and woollens, and has some trade in corn and Tokay wine; whilst in the vicinity are the Sovar saltworks. Pop. 10,139.

**Epernay**, a town in the French department of Marne, is the headquarters of the *Vins de Champagne*, and is situated in the midst of a rich vine-growing district, on the left bank of the Marne, 19 miles WNW. of Chalons. It is handsomely built, clean, and well paved. Its environs consist, for the most part, of elegant villas, with vaults attached, belonging to the Champagne wine-merchants. Epernay manufactures large quantities of earthen-

ware from a clay obtained in the neighbourhood, and called *Terre de Champagne*; also hosiery, refined sugar, and leather. It has a brisk trade in bottles, corks, wine, &c., as well as wine. Pop. (1872) 12,877; (1886) 17,799.

**Ephah**, a measure of capacity in use among the Hebrews, equivalent to about 8½, or, according to others, 6-468, imperial gallons.

**Ephemera** ('day-fly' or 'May-fly'), a genus of well-known insects which appear in vast numbers on summer evenings from rivers, canals, and ponds, and after a short merry life disappear as suddenly as they came. The genus *Ephemera* is type of the family Ephemeridae or May-flies in the wide sense. The family is often ranked within the Pseudoneuroptera sub-order of Orthoptera, not far from Dragon-flies.

A thin delicate body, with filmy wings, of which the anterior are much the larger and sometimes the only pair; rudimentary mouth-parts in the adults, which fast throughout their short aerial life; a long-lived voracious larval existence in the water, with so-called tracheal gills for aquatic respiration, are striking features of the Ephemerids. The antennae are short and awl-shaped; the eyes of the males are very large; the head-shield is enlarged, covering the rudimentary mouth-parts; the middle ring of the thorax is exaggerated; the legs are delicate; the thin abdomen ends in two or three long filaments.

The life-history of these delicate ephemeral insects is very interesting. The eggs are laid in the water and give rise to aquatic larvae, which live sometimes two or three years, moulting many times.

Metamorphoses of the May-fly.

They prefer running water, hide under stones or make burrows in the mud, have well-developed mouth-parts, and feed hungrily enough on other insects. The tracheae or air-tubes, as the figure shows, are expanded in plate-like or tuft-like paired structures down the sides of the posterior body. A pupa stage eventually follows, during which the larva acquires wings and other adult structures, but the insect which emerges and leaves the water is, curiously enough, not yet ready for its short adult life. Though it has wings, it is still encumbered by a delicate robe. This sub-imago, as it is often called, finds some resting-place on grass stem or tree trunk, gets rid of its last enumberance, and begins its life of a day. The cast-off ghost-like exuviae are found in great

numbers. In the summer evening the males and females enjoy a brief merry love-dance. The females are fertilised, the eggs are dropped into the water, and then sometimes in a single day the bright crowd is gone. It is literally true that at the moment of their climax they die.

The most familiar species is *Ephemera vulgata*, the common May-fly, the green drake (sub-imago) and gray drake of anglers. Palingenia, Heptagenia or Bætis, Cloë, Caenis, are almost common genera. The adult larvæ are used for bait; the corpses of the adults are sometimes abundant enough to serve as manure. The Ephemerids date back to the Devonian epoch. See ANGLING.

**Ephemera** (from Gr. *epi* and *hēmera*, 'on a day'), or FEBRIS DIARIA in Latin, a fever which lasts only a single day, or part of a day, and is generally dependent on some slight local irritation. It hardly requires any other treatment than the removal of the cause, if known.

**Ephemeris** (Gr., 'for the day'). See ALMANAC, and DIARY.

**Ephesians.** EPISTLE TO THE, one of the letters attributed to the apostle Paul, and supposed to be written during his imprisonment either at Cæsarea or at Rome. It falls into two parts, separated by the doxology, iii. 20, 21, the first part being doctrinal and the second practical. The earliest MSS. have not the words 'at Ephesus' in i. 1, and the hypothesis of Ussher (1630) that the letter was an encyclical writing sent to a number of churches in proconsular Asia has found favour with many scholars. Some hold that it is 'the epistle from Laodicea' mentioned in Col. iv. 16, and Tertullian tells us that Marcion called it the 'Epistle to the Laodiceans.' It has a very remarkable similarity to the Epistle to the Colossians, and De Wette held that it is 'little more than a verbose amplification' of the latter; but Holtzmann has shown that each of the two epistles is equally indebted to the other. Its authenticity, denied by De Wette (1843) and most later critics, has been defended (among others) by Rückert, Klöpper, Schenkel, and Renss.

See the special commentaries by Rückert (1834), Eadie (1854), Hodge (1856), Elliott (3d ed. 1864), Ewald (1870), and Dale (1882); also H. Holtzmann, *Kritik der Epheser und Kolosserbriefe* (1872).

**Ephesus**, one of the twelve Ionic cities of Asia Minor, was situated in Lydia, near the mouth of the river Cayster, in the midst of an alluvial plain. It was long before Ephesus acquired any political importance, in spite of being a sacred city from an early period. Subdued first by the Lydian, and next by the Persian kings, it was included, after the death of Alexander the Great, in the territories of Lysimachus (281 B.C.), by whom it was greatly strengthened. Ultimately it came into the possession of the Romans; and in the time of Augustus, when Strabo wrote, it was 'the greatest place of trade of all the cities of Asia west of the Taurus.' This was also its condition when visited by St Paul, who resided here three years; but the destruction of its great temple by the Goths, in 262 A.D., gave it a blow from which it never recovered. In 431 it was the scene of the third general council of the Christian Church. Its general history, while a city of the Byzantine empire, was unimportant, and before the days of Tamerlane it had almost completely perished.—The ruins of Ephesus comprise a stadium 687 feet long, fragments of a great theatre (alluded to in the account of St Paul's preaching in the city), of an odeum or music-hall, and of various walls and towers, belonging to the Greek, Roman, and Byzantine eras. About a mile north-east of the ancient city was the site of the famous Temple

of Diana. This marvellous building, one of the seven wonders of the world, was originally built by Chersiphron; but on the night (as is said) when Alexander the Great was born (356 B.C.), it was fired by Herostratus, an Ephesian, thereby to immortalise his name. It was afterwards rebuilt by the inhabitants in a style of greater splendour than before, the very women contributing their ornaments to secure the necessary funds. It was the largest Greek temple ever constructed. Its length, according to Pliny, was 425 feet, its width 220; and the number of its columns 127, each 60 feet high. The site of the temple was discovered by Mr Wood in 1869, and excavations, continued until 1874, have greatly extended our knowledge of this 'wonder of the world.' But even more wonderful than the temple itself were the numberless statues and pictures which it contained, executed by the best masters of Greece. The altar of the goddess was principally adorned with the works of Praxiteles. Plundered of its treasures by Nero, and burned (as has been mentioned) by the Goths, it was most likely finally destroyed by the iconoclasts, in the reign of Theodosius I., who issued his celebrated edict against the ceremonies of the pagan religion 381 A.D. The site of Ephesus is now occupied by some wretched villages, the principal of which is Ayasuluk.

See Falkner, *Ephesus and the Temple of Diana* (1862); J. T. Wood, *Discoveries at Ephesus* (1877); Feigsson, *The Temple of Diana at Ephesus* (1883); and the articles ARTEMIS and SEVEN SLEEPERS.

**Ephod** (called in the LXX. *epōmis*; in Vulg. *superhumeralis*), a principal part of the official dress of the Jewish High-priest (q.v.). The description of its form in Exodus, xxviii. 6 *et seq.*, and xxxix. 2 *et seq.*, is not quite clear, and the common notion that it consisted of two shoulder-pieces, one on the back and the other on the breast, and fastened together by onyx-stone brooches, is incorrect. It may be described as a vest covering the breast and waist, open in front, and continued behind over the back up to the neck, where it divided into two cape-like ends, which were extended to cover the shoulders both before and behind. These ends being fastened in front above the breast, and the vest below being also fastened by a band of one piece with it, kept the ephod firmly on the body, while the arms were left free. The material of the ephod was of gold thread, and blue, purple, scarlet, and white twined byssus yarn. On the top of each shoulder was placed an onyx stone. The stones were inclosed in 'ouches' of plaited gold, and were not used as brooches, but as significant ornaments, the names of the twelve tribes being engraved on them—six on each.

An essential part of the high-priest's ephod was a square bag made of the same materials, and serving as a receptacle for the Urim and Thummim (q.v.). It was a span long each way, and was placed over the middle of the front part of the ephod, and just above its waist-band, being suspended from the shoulder-parts of the ephod by rings and chains of gold. On its front side it had twelve precious stones, the name of each on each stone.—Ephods were worn in the time of Samuel and Saul by all priests. According to some scholars, the golden ephod of Gideon at Ophrah (Judges, viii. 27) was a kind of image.

**Eph'ori** (Gr., 'overscers'), an order of magistrates in ancient times which appears to have originated at Sparta, and to have been peculiar to the Doric governments. Herodotus attributes their creation to Lyncurgus, and Aristotle to Theo-

pompus (770-720 B.C.). Their duty was to superintend the internal administration of the state, especially affairs of justice, and to oversee some part of the education of youth. They were five in number, were elected by and from the people—on which Aristotle observes that through them the *demos* enjoyed a participation in the highest magistracy of the state—and held their office only for one year. Their influence gradually increased, for their powers were so ill defined that it was difficult to say what was *not* under their cognizance and authority. Ultimately the kings themselves became subject to the supervision of the ephori; thus, Cleomeues was brought before them for bribery, Agesilaus was fined, and Pausanias imprisoned. They also transacted the negotiations with foreign powers, subscribed treaties, raised troops, intrusted the army to the king or some other general, and, in fact, acted as the executive of the state. Their authority was at last destroyed by Agis and Cleomeues, who put the whole college to death, and restored the old Spartan constitution (226 B.C.). See Dum, *Entwicklung des Spartanischen Ephorats* (1878).

**Ephraem Syrus**, 'the prophet of the Syrians,' a celebrated teacher, orator, and hymn-writer of the Syrian Church, was born at Nisibis about 306. After Nisibis was taken by the Persians in 363 he removed to a cave near Edessa, which was already a chief seat of Syrian learning. He there devoted himself to prayer and fasting, and the study of the Scriptures. He died at Edessa about 378. His day is in the Roman Church the 1st of February, and among the Greeks and Maronites the 28th of January. Ephraem's strict orthodoxy, his asceticism, and his great learning were the admiration of his contemporaries; and the works he has left behind him, written in a fervid and popular style, sustain his reputation as an orator and poet. He was a most fertile writer. Part of his works have come down to us in their original Syriac, part in Greek, Latin, and Armenian translations. Of the Syriac writings the chief are his commentaries (based on the Peshito), extending to nearly the whole of the Old Testament, and they include also numerous discourses and elegies, mostly written in lines of seven syllables, grouped in strophes of from four to twelve lines each. Ephraem counteracted the influence of the Gnostic hymns of Bardesanes and Harmonius by writing better hymns of a strictly orthodox tendency. The Greek writings which bear his name are mainly sermons and short religious treatises. An edition containing 156 of these was published by Edward Thwaites at Oxford in 1709. The standard edition is that of Assemani, in 6 vols. folio (3 vols. Greek texts, and 3 vols. Syriac texts, with Latin translations, Rome, 1732-46). The Syriac text of his select works was edited by Overbeek (Oxford, 1865). A tasteful English translation of a number of pieces by Ephraem was published by Henry Burgess, under the titles *Select Metrical Hymns and Homilies of Ephraem Syrus* (3 vols. 1853). Ephraem's Commentaries on the Epistles of St Paul are extant in Armenian (ed. by Aucher, Venice, 1836). See treatises on Ephraem and his works by Lengerke (1831), Alsleben (1853), Gerson (1868), and Zingerle (1876).

**Epiplast.** See ECTODERM, EMBRYOLOGY.

**Epicharmus**, a famous Greek poet, was born in the island of Cos, in the 6th century B.C. He spent the latter part of his life at the court of Hiero of Syracuse, and died at the age of ninety. Epicharmus is called by Theocritus the father of comedy, and Plato assigns to him a place among comic writers as high as that of Homer among epic poets. None of Epicharmus's works survive entire;

but we possess several fragments and the titles of thirty-five. They embraced a wide variety of topics, mythological, social, and political. From one of them Plautus borrowed the plot of his *Menæchmi*. See Lorenz, *Leben u. Schriften des Epicharmus* (1864).

**Epic Poetry** (Gr. *epos*, 'a word,' 'a discourse') is that class of poetry which produces an imaginative description of events, real or fictitious, but considered as having already happened; as opposed to lyric poetry, which is an imaginative expression of internal subjective emotions with respect to external and objective facts. Of more complex character than the narrative ballad poem, the epic obviously is one of the earliest poetical forms in which the primitive imagination has found expression. It is impossible to classify the epics of various races, but a distinction has been made between 'epics of growth,' which consist of collections of ballads or poems composed by different authors, at different times, and dealing with a connected series of events, such as the *Mahabharata*, the Nibelung story (Icelandic version), and the *Kalevala*, as contrasted with 'epics of art,' in which the events are grouped around some great structural thought by a single poet, like the *Odyssey*, the *Æneid*, *Paradise Lost*, and *Jerusalem Delivered*. Such epics as the *IlIad* and the *Shah Nameh*, again, belong to both classes at once. The term heroic epic, or heroic poem, is properly applied to such works as the *IlIad* and *Odyssey*, Virgil's *Æneid*, the *Poem* proper of the Cid, Tasso's *Jerusalem Delivered*, and Ariosto's *Orlando Furioso*, and others, which describe the achievements of the gods and heroes of antiquity, or of the little less mythic knights of medieval chivalry. Poems, again, like Milton's *Paradise Lost*, Spenser's *Faerie Queene*, and Dante's *Divina Commedia*, are sacred epics; Lucan's *Pharsalia* and the *Lusiads* of Camoens, historical epics. Such poems as Scott's *Marmion* are genuine miniature epics, while Tennyson's *Idylls of the King*, from its artistic consecutiveness of motive, belongs also to the family; to quite another class—the mock-epic—belong such poems as Pope's *Rape of the Lock*, Butler's *HuIubras*, and the like. Poems of epic character are still written by ambitious poets, the fate of Glover's *Leonidas* not serving as sufficient warning; but the real epic of our modern civil and domestic life is the prose novel. The narrative and the descriptive poem are still written, but seldom with much success at great length. Even the dramatic poem in its ancient sense seems a form uncongenial to modern wits.

**Epictetus**, a celebrated disciple of the Stoa, was born at Hierapolis, in Phrygia, about 50 A.D. He was at first the slave of Epaphroditus, a freedman of Nero, at Rome, and endured his severe treatment with characteristic stoic equanimity. After being manumitted he devoted himself to philosophy, and was banished by Domitian, along with several other philosophers, from Rome. He settled at Nikopolis, in Epirus. He left no works behind him, but his pupil Arrian, the historian of Alexander the Great, collected his maxims with affectionate care, in the work entitled *Enchiridion* ('Handbook') and in eight books of Commentaries, four of which are lost. These reveal the simple and noble earnestness of the philosopher's character; as well as that real heartfelt love of good and hatred of evil which is often assumed to be an exclusively Christian feeling. Epictetus believes in our 'resemblance' to God, in our 'relationship' to him, and in our 'union' with him through the coincidence of the 'will' and the 'soul'; he recognises the contest between good and evil, the life-struggle in the heart, the divine life against which the law in the members wars; and he affirms the necessity of

'invoking God's assistance in the strife,' that the inner life may become pure as God is pure. His ethics teach self-renunciation, endurance, and the duty of confining the ambition within the limits of the attainable. The most complete edition is that of Schweighäuser (5 vols. 1799-1800). See STOICS.

**Epicurus**, an illustrious Greek philosopher, was born 341 B.C., in the island of Samos, where his father, Neocles, was a schoolmaster. At the age of eighteen he repaired to Athens, but his stay was short, and he returned to Asia. He had attached himself to the study of philosophy, especially that of Democritus; his own scheme of physics is evidently based on the atomic system of Democritus. At Mitylene, in his thirty-second year, he first opened a school of philosophy; and there and at Lampsacus he taught for five years. In 307 B.C. he returned to Athens, and established a school of philosophy in a garden which he purchased and laid out for the purpose. From this circumstance his followers were called the 'philosophers of the garden.' Although Epicurus laid down the doctrine that pleasure is the chief good, the life that he and his friends led was one of the greatest temperance and simplicity. They were content, we are told, with a small cup of light wine, and all the rest of their drink was water; and an inscription over the gate promised to those who might wish to enter no better fare than barley-cakes and water. The calumnies which the Stoics circulated concerning him are undeserving of notice, and were at no time generally believed. Epicurus's success as a teacher was signal; great numbers flocked to his school from all parts of Greece and from Asia Minor, most of whom became warmly attached to their master, as well as to his doctrines, for Epicurus seems to have been characterised not less by amiability and benevolence than by force of intellect. He died 270 B.C., in the seventy-second year of his age.

Epicurus was a most voluminous writer. According to Diogenes Laertius, he left 300 volumes on Natural Philosophy, Atoms and the Vacuum, Love, the Chief Good, Justice, and many other subjects. These works are lost: the only writings of Epicurus that have come down to us are three letters, a few fragments from the *Volumina Herculanensis*, and a number of detached sentences or sayings, preserved by Diogenes Laertius. The principal sources of our knowledge of the doctrines of Epicurus are Cicero, Plutarch, and, above all, Lucretius, whose great poem, *De Rerum Natura*, contains substantially the Epicurean philosophy.

Although the majority of Epicurus's writings referred to natural philosophy, he seems to have studied nature with a moral rather than a scientific design. According to him, the great evil that afflicted men—the incubus on human happiness—was fear; fear of the gods and fear of death. To get rid of these two fears was the ultimate aim of all his speculations on nature.

He regarded the universe (*to pan*) as corporeal, and as infinite in extent and eternal in duration. He recognised two kinds of existence—that of bodies, and that of *vacuum*, 'the void'—i.e. space, or the intangible nature. Of his bodies, some are compounds, and some atoms or indivisible elements, out of which the compounds are formed. The world, as we now see it, is produced by the collision and whirling together of these atoms. He also held the doctrine of perception by *images* (Gr. *eidōla*), which are incessantly streaming off from the surface of all bodies, and which are necessary to bring us into *rapport* with the world without. In psychology he was a materialist, holding that the soul is a bodily substance, composed of subtle particles disseminated through the whole frame.

In seeking to understand the phenomena of the

heavens he has no scientific end in view; his sole object is to enable the mind to account for them to itself, without the necessity of imagining any supernatural agency at work. He did not deny that there are gods; but he strenuously maintained that as 'happy and imperishable beings' they could have nothing to do with the affairs of the universe or of men. 'Beware,' he says, 'of attributing the revolutions of the heaven, and eclipses, and the rising and setting of stars, either to the original contrivance or continued regulation of such a being. For business, and cares, and anger, and benevolence are not accordant with happiness, but arise from weakness, and fear, and dependence on others.'

Having proved in his psychology that the dissolution of the body involves that of the soul, Epicurus argues that the most terrible of all evils, death, is nothing to us, 'since *when we are, death is not; and when death is, we are not*. It is nothing, then, to the dead or the living; for to the latter it is not near, and the former are no longer in existence.'

He held that pleasure was the chief good, and it is from a misapprehension of the meaning of this word as used by him that the term Epicurean came to signify one who indulged his sensual appetites without stint or measure. At the same time, it is easy to see that the use of the word 'pleasure' was calculated to produce the mischievous results with which the later Epicureanism was charged. (For the Cyrenaic hedonism, see ARISTIPPUS.) According to Epicurus, the sources and tests of all ethical truth are the feelings, and these are two, pleasure and pain. We delight in the one, and avoid the other instinctively. 'When we say that pleasure is the end of life, we do not mean the pleasures of the debauchee or the sensualist, as some from ignorance or from malignity represent, but freedom of the body from pain, and of the soul from anxiety. For it is not continuous drinkings and revellings, nor the society of women, nor rare viands, and other luxuries of the table, that constitute a pleasant life, but sober contemplation that searches out the grounds of choice and avoidance, and banishes those chimeras that harass the mind.' Epicurus rests justice on the same prudential basis as temperance. Denying any abstract and eternal right and wrong, he affirms that injustice is an evil, because it exposes the individual to disquietude from other men; justice is a virtue, because it secures him from this disquietude. The duties of friendship and goodfellowship are inculcated on the same grounds of security to the individual.

Among the Romans the system of Epicurus was adopted by many distinguished men. Horace, Atticus, and Pliny the Younger were Epicureans; Seneca, nominally a Stoic, drew much from Epicurus; and the great poem of Lucretius must have recommended the system to many. In modern times Epicureanism was resuscitated in France by Père Gassendi, who published an account of Epicurus's life and a defence of his character in 1647; and many eminent Frenchmen have professed his principles.

See ATOM, DEMOCRITUS, LUCRETIVUS; Zoller's *Philosophy of the Stoics, Epicureans, and Sceptics* (trans. by Reichel; new ed. 1880); W. Wallace, *Epicureanism* (1880); and monographs by Glzycki (Halle, 1879) and Kreibitz (Vienna, 1885).

**Epicycle.** See PROLEMAIC SYSTEM.

**Epicycloid** is the name of a peculiar curve. When a circle moves upon a straight line, any point in its circumference describes a Cycloid (q.v.); but if the circle moves on the convex circumference of another circle, every point in the plane of the first circle describes an epicycloid; and if on the concave circumference, a hypocycloid. The circle that moves is the generating circle; the other, the base. The describing point is not necessarily in the

circumference of the generating circle, but may be anywhere in a radius or its prolongation. It has many remarkable properties, and is even useful in the practical arts. The teeth of wheels in machinery must have an epicycloidal form, in order to secure uniformity of movement.

**Epidaurus**, a town of ancient Greece, on the eastern shore of the Peloponnesus, in the district of Argolis. During the most prosperous period of Grecian history Epidaurus was an independent state. The form of government was originally monarchical, but, after many vicissitudes, it eventually became and remained oligarchical. At an early period Epidaurus became one of the chief commercial cities of the Peloponnesus. It was chiefly famous for its temple of *Æsculapius*, to which patients resorted from all parts of the Hellenic world, seeking a cure for their diseases. The site of this temple, about 5 miles west of the town, is still called Hieron, 'the sanctuary.' Epidaurus had also numerous temples and a magnificent theatre, at present in a more perfect state of preservation than any in the Peloponnesus, and with sufficient accommodation for 12,000 spectators. At the modern *Epidavro*, a small village, in January 1822 a congress from all parts of Greece assembled, and promulgated the constitution known as the constitution of Epidaurus.

**Epidemic** (Gr. *epi*, 'upon,' and *dēmos*, 'the people'), a disease which attacks numbers of persons in one place, simultaneously or in succession, and which in addition is observed to travel from place to place, often in the direction of the most frequented line of communication. In early days, before the doctrine of contagion was advanced, it was thought that the cause of all disease, both endemic and epidemic, existed in the atmosphere. Hippocrates, while recognising this conclusion as correct regarding the former class of disease, ascribed the latter to something divine or to some unknown and inexplicable cause. Sydenham, the father of English medicine, took a similar view, believing that epidemic diseases were to be attributed to 'a hidden constitution of the air.' Hence the term so frequently used, even in later days, of 'the epidemic constitution.' No doubt there is some foundation for this, seeing that all the great epidemics of ancient time—notably the famous pestilence of the 14th century known as the Black Death—were preceded or accompanied by violent climatic changes, earthquakes and other geological disturbances. But in our age, with the advance that has been made in medical research, the majority of physicians and scientific men are agreed that there is no necessity to go out of the way to seek for an ill-defined and mysterious cause for epidemics, but that the matter may be fairly attributed to well-ascertained and clearly intelligible influences. Examples of these may be adduced in the effect of poverty and overcrowding upon typhus, and inefficient sanitation in the production of typhoid. That famine has much to do with epidemic disease is generally well recognised, so much so that one particular form—relapsing fever—is commonly known as the famine fever. It must still be admitted that there is room for argument on the subject, and so recently as 1884 Dr Norman Chevers, then president of the Epidemiological Society, at a meeting held in connection with the Health Exhibition, attributed typhus fever to the prevalence rather of what he termed an atmospheric wave than to any effect produced by badly ventilated dwellings, though he admitted that this, like the drinking of impure water in cases of typhoid, might be the exciting cause (Health Exhibition Conferences). Epidemics are transmitted from person to person, it is now all but univers-

ally agreed, through the medium of minute living organisms, varying in nature according to the different classes of disease. Among the more famous epidemics may be mentioned the Black Death, already alluded to; the Sweating Sickness, which first made its appearance in England in 1485, and afterwards in this and succeeding years became very conspicuous; and a peculiar form of epidemic affection, characterised by gangrene of the hands and feet, which was variously known to ancient writers as *Ignis Sacer*, *Arsenica*, *Mal des Ardens*, and at a later period as *St Anthony's Fire*. The chief epidemics of the 19th century have been cholera, diphtheria, cerebro-spinal meningitis, yellow fever, and relapsing fever. See ENDEMIC for further information on this subject; also CONTAGION, INFECTION, FEVER, CHOLERA, PLAGUE, SMALL-POX, &c.

**EPIDEMIC MENTAL DISEASES.**—When we consider how ordinary and normal thoughts and emotions spread from one man to many, and sway multitudes to the same views and actions, it is no longer a mystery that morbid conditions of the mind should become at times no less epidemic than physical diseases. Such, at least, is the fact. A mental disorder may spread from man to man, and may involve whole nations. It depends for its propagation, like an epidemic disease, first upon external circumstances, and secondly, upon the peculiar condition or constitution of the individuals affected. Like the bodily affection, the causes which provoke the insanity and the tendency to be affected may have been in process of development for years. Both attack the weak rather than the strong; both exist for a season, and disappear. In the case of the mental malady, the external influences—those which constitute the moral atmosphere—are ignorance or imperfect knowledge, the power of one mind over another, the influence of language, the diffusion of particular opinions, the tendency to imitate. It is probable, however, that physical causes exercise an important influence in the production of such general mental conditions. In 1842 and 1844 there occurred in Germany and France, among the military, epidemics of meningitis with delirium, or inflammation of the membranes of the brain, when no moral factors were at work, but when diet, temperature, &c. were to blame. But even where the origin cannot be so distinctly traced, the co-operation of external as well as psychical agents may be legitimately predicated. It would accordingly be illogical to limit the production of the Dancing Mania (q.v.), which occasionally, during several centuries, swept over Europe, to the reaction succeeding the dread of the end of the world, which had previously prevailed epidemically. An examination of about a hundred manifestations such as that alluded to, collected from various sources, demonstrates that not merely the intoxication of joy, but the most absurd forms of belief—that dreams, delusions, superstitions, corruptions of language, all instincts and passions, even movements and cries, may assume the form, and, to a certain extent, may follow the laws of epidemic diseases. There are records of a histrionic plague, when crowds conceived themselves players, and traversed the streets, and sank and died, repeating verses, and exhibiting extravagant gesticulations; and of whole communities being stricken with nightmare, which was so general as to be supposed contagious. There have been epidemics of homicidal and suicidal mania. In one age hundreds are found possessed by Satan; in another, larger numbers converted into wolves; and the leaping ague of Forfarshire in the 18th century and outbursts of pyromania in various places remind us that there may be still in the constitution of the human mind, and in the education and the habits

of life prevailing, elements capable of realising the catastrophe suggested by Bishop Butler's question: What is to prevent a whole nation becoming mad? The instances of epidemic mental disease recorded in the following table have been selected from a vast number of others, with a view of showing not the frequency or extent of such affections, but the range of the phenomenon through the powers and propensities of our nature.

Popular Name.	Form of Disease.	Year.
St Vitus's Dance.....	Chorea magna.....	1374.
Wolfsolf Superstition.....	Lycanthropia.....	Various.
Possession.....	Demonomania.....	1642, &c.
Convulsionaries.....	Theomania.....	1781.
Incendiarism.....	Pyromania.....	1800.
Witchcraft.....	Demonopathia.....	Various.
Smells.....	Melancholia.....	"
Visions.....	Delusions.....	"

There appears to be no guarantee that the present and future generations shall be exempted from similar visitations, except in the universal diffusion of knowledge and sound thinking, for it is invariably in the darkness of ignorance or in the twilight of imperfect knowledge that the moral plague comes.

See DISEASES, INSANITY, FLAGELLANTS; Hecker's *Epidemics of the Middle Ages* (Eng. trans. 1846); Calmeil, *De la Folie* (Paris, 1845); Ackermann, *Ueber die Ursachen epidemischer Krankheiten* (Berl. 1873); Knechtmeister's *Zeitschrift für Epidemiologie* (1874 *et seq.*); *Psychological Journal* (passim); Parkin's *Epidemiology* (2 vols. 1880).

**Epidermis** (Gr. *epi*, 'upon,' and *derma*, 'the skin'), scarf-skin or cuticle, forming an external covering of a protective nature for the true skin or corium. Its under or attached surface is accurately moulded upon the true skin, and when the two are separated the cuticle presents impressions which exactly correspond to the elevations and depressions in the corium. The thickness of the epidermis varies from  $\frac{1}{16}$  to  $\frac{1}{8}$  of an inch, according to the amount of protection which the delicate and sensitive corium requires in different localities.

Thus, it is thickest and hardest in the palms of the hands and soles of the feet, but this is not altogether the result of an increased growth due to intermittent pressure, for the difference is well marked even in the fœtus. The epidermis consists of many layers of stratified cells superimposed on each other; and since they cover a free surface exposed to the air, the cells are classed in the group of stratified epithelia. The cells vary in shape, those placed next the

Perpendicular Section of the Skin of the Leg of a Negro (magnified 250 diameters):

a, a, papillæ of the cutis; b, deepest intensely coloured layer of perpendicularly elongated cells of the mucous layer; c, upper stratum of the same layer; d, horny layer.

corium being elongated in form, while those most superficial are flat and scale-like. On this account it is usual to describe the epidermis as consisting of two strata—an outer or *superficial horny stratum*, and a deeper or *mucous stratum* (or *rete Malpighii*). The *horny stratum* consists of cells, many of which have lost their nuclei and assumed the form of hard flattened scales of

polygonal outline. The deepest layer of this stratum consists of closely packed cells with indistinct outlines and a clear, almost homogeneous, appearance, which has given them the name of the *stratum lucidum*. The superficial cells of the horny layer are regularly cast off by desquamation, and replaced by those beneath them. In reptiles and amphibians this layer is periodically cast off in a more or less entire state, a new one being previously formed beneath it; and in man desquamation in large patches occurs after certain diseases, especially scarlet fever.

The *mucous stratum* lies next the corium. It consists of nucleated cells of various shapes. Those next the corium are elongated and placed perpendicularly to its surface. Above these are cells more rounded or polyhedral in outline, and possessing many spines or prickly-like processes, by the points of which the cells adhere to each other, and thus leave fine lymph channels through which the nutrient plasma is transmitted to the cells. The colouring matter of the epidermis is found in the cells of the mucous stratum. A more or less dark pigment is often deposited in the face, neck, and hands of the fair races of men during exposure to the sun, forming isolated colour-spots called freckles; but in the dark races the pigment-granules are distributed throughout the cells of the mucous stratum, the deepest or perpendicular cells being the darkest. Instances of white negroes are on record, not as a consequence of change of climate, but as an abnormal condition of the epidermis. Fine nerve-fibrils penetrate between the cells of the mucous stratum, and undergo a certain amount of ramification, but do not form a network. In some reptiles, and in the Edentata among mammals, the epidermis forms large plates or scales, while epidermal appendages assume various forms—e.g. hair, nail, spines, bristles, feathers, claws, hoof, horns, &c.

In *plants* the epidermis is formed of flattened cells, usually only one layer deep, frequently bearing hairs and stomata. The exposed cell-walls upon the outer surface are frequently thickened as the cuticle.

**Epidote.** Under this name are included several minerals, which are of some importance as rock-formers. Only two need be mentioned here, *Zoisite* and *Pistaxite*, or *Epidote proper*. Zoisite, or lime-epidote, is a silicate of alumina and lime, the alumina sometimes being replaced by ferric oxide to the extent of 2 or 3 per cent. It crystallises in rhombic prisms, which are often curved or sharply bent. Usually it occurs as large imbedded crystals or as foliated and columnar aggregates, chiefly in crystalline schists, especially such as are rich in amphiboles. It is generally light-coloured—white, yellowish, or brownish-gray. Its hardness = 6½. Pistaxite, or epidote proper, is a silicate of alumina and lime in which the alumina is replaced by ferric oxide up to 17 per cent. or thereabout. Hence it is often spoken of as iron-epidote. It has a peculiar dark yellowish-green colour, known as pistachio-green. It crystallises in monoclinic prisms, and has a hardness similar to that of zoisite. The largest and best developed crystals are met with amongst the crystalline schists and gneisses, and not infrequently in metamorphosed limestones. In eruptive rocks it occurs only as a decomposition-product after pyroxenes, amphiboles, micas, and felspars.

**Epigastrium** (Gr. *epi*, 'over,' and *gaster*, 'the stomach'), the part of the Abdomen (q.v.) which chiefly corresponds to the situation of the stomach, extending from the sternum towards the navel or umbilicus. It is called in popular language the pit of the stomach.

**Epigene** (Gr. *epi*, 'upon,' *gennaō*, 'I produce'), a term applied to those geological agents of change which affect chiefly the superficial portions of the earth's crust, as the *atmosphere, water, plants, and animals*. See GEOLOGY.

**Epigenesis**, a technical name for the modern conception of the development of the organism by the growth and differentiation of a simple germ—i.e. by the division or segmentation of a fertilised egg-cell. This conception, now a commonplace, was first definitely enunciated by Harvey (1651), and was reasserted with cogent demonstration by Wolff in 1759, in opposition to the generally received theory that the germ contained a pre-formed miniature model of the organism which only required to be unfolded. See EMBRYOLOGY.

**Epi-glottis**, a cartilaginous valve which partly closes the aperture of the larynx. See LARYNX, and DIGESTION.

**Epigoni**. See ADRASTI.

**Epigram**, a word derived from the Greek and literally signifying an 'inscription.' The epigrams of the Greeks were simply inscriptions on tombs, statues, and monuments, written in verse, and marked by great simplicity of style, but having little in common with what is now understood by the name. The founder of the art was Simonides of Ceos, many of whose epigrams were inscribed on the tombs of the heroes who fell in the Persian war. It was among the Romans that the epigram first assumed a satirical character; the greatest Roman masters were Catullus and, in particular, Martial, whose obscenity unhappily was more easily imitated than his genius. In modern times an epigram is understood to be a very short poem, generally from two to eight lines, containing a witty or ingenious thought expressed in pointed phraseology, and in general reserving the essence of the wit to the close, as the serpent is failed to keep its sting in its tail. It may be the medium for the expression of almost any feeling, provided only it is in form brief, pointed, and exquisite. Epigram, however, fits best the expression of satire—an admirable example is that of Rogers:

Ward has no heart, they say, but I deny it;  
He has a heart, and gets his speeches by it.

The Latinists Scaliger, Buchanan, More, Stroza, and John Owen (1560-1622) wrote epigrams, and the form has been kept in an artificial life by Vincent Bourne, Porson, and Walter Savage Landor. And the excellent *Epigrams of Art, Life, and Nature* (1884), by William Watson, show that the art is not yet quite forgotten. In earlier generations of English literature the epigram was a favourite form, almost every poet in the 16th and 17th centuries having written them. John Heywood 'invented and did' as many as six hundred; other past but forgotten masters are Thomas Freeman, Samuel Sheppard, Thomas Bastard, Thomas Bancroft, and Henry Parrot. A few examples by Herrick, Quarles, and Ben Jonson still survive, while many thousands that cost much labour in the making sleep in secure oblivion. The French excel all other nations in the epigram. Their earliest epigrammatist of any note was Clement Marot (1495-1544); their best are J. B. Rousseau, Lebrun, Voltaire, Marmontel, Piron, and Chénier. The epigrams of German writers are for the most part happily expressed moral proverbs (*Sinngedichte*), but the *Xenien* of Schiller and Goethe contain not a few sharp and biting verses of a satirical character. Logau's famous *Deutscher Sinngedichte Drey Tausend* appeared in 1654; later epigrammatists were Kleist, Opitz, Gleim, Hagedorn, Klopstock, A. W. Schlegel, Lessing, and Herder. A large col-

lection of English epigrams was that of Weever (1599). Good epigrams have been written by Cowley, Waller, Dryden, Prior, Swift, Addison, and Young; but the greatest master of the epigrammatic spirit in our literature is Pope. See Booth, *Epigrams, Ancient and Modern* (1863); Dodd, *Epigrammatists of Medieval and Modern Times* (2d ed. 1875); and W. D. Adams, *Book of Epigrams* (1879).

**Epigraph** (Gr. *epi*, 'upon,' and *graphō*, 'I write'), a terse inscription placed upon architectural or other monuments, for the purpose of denoting their use or appropriation, and very frequently worked in and forming part of their ornamental details. See INSCRIPTIONS; and E. S. Roberts, *Introduction to Greek Epigraphy* (Cambridge Univ. Press, 1883).

**Epilepsy** (*epilepsia*, 'a seizure') is a chronic functional disease of the nervous system, manifested by recurring attacks of sudden insensibility or impairment of consciousness, commonly accompanied by convulsive seizures of a peculiar kind. The term is not now applied to such symptoms when they are due to organic disease of the brain, heart, or other organs. Thus, we apply the name syncope to sudden unconsciousness from failure of the heart; and we speak of Eclampsia (q.v.) or epileptiform convulsions when the cause is apoplexy, or tumour of the brain, or disease of the kidneys, or teething. It is the underlying morbid condition, not the mere seizures, that constitutes the disease. Epilepsy affects all races of man, and is not unknown among lower animals. Its striking phenomena have been described by the oldest medical writers. By the ancients it was regarded as due to demonic possession, or to the anger of an offended deity. Their physicians, likewise considering its cause to be supernatural, called it the *morbus sacer*. Hippocrates alone, to his credit be it said, maintained that its origin was no more supernatural than that of any other disease. The Romans regarded it as an evil omen if any one took a fit during the conduct of public business, and adjourned the meeting for the day. Hence they termed it *morbus comitialis*. The common English name, derived from one of its most prominent symptoms, is the 'falling sickness.'

The phenomena of the disease are so multiform that it is impossible here to do more than describe the main types of its severe, slight, and irregular forms. (1) In the *severe form*, or epileptic 'fit' proper (the *grand mal* of the French), the patient, it may be without warning, utters a strange inarticulate cry, and falls suddenly to the ground insensible, as if struck by lightning. He usually has no time to save himself, but knocks against any object near him, and may thus receive serious injury, or he may fall into the fire, or into water. He becomes deadly pale, his body rigid, with the back arched and the features set, and he ceases to breathe. Soon the colour changes, the face becomes livid purple, the veins of the neck swell up and pulsate, the eyeballs protrude, a gurgling sound is heard in the throat, and death seems imminent. But almost immediately breathing begins again, and the whole body is thrown into a series of successive convulsive twitchings or jerks. The trunk and limbs are thrown about in various ways, the face is hideously contorted, the tongue jerked out between the teeth and often bitten, the jaws convulsed so that the teeth may be broken. A blood-stained foam escapes from the mouth. After about two or three minutes the jerks cease, leaving the patient prostrate and comatose for a time. Then he may open his eyes, look around him with a dazed expression, and go to sleep. On awaking he is quite unconscious of what has

happened; he may have a severe headache, or be morose and irritable; in rare cases, he feels much freer mentally than before the fit. Sometimes a condition of homicidal mania follows the fit, when the patient attacks any one he may see. The fits are usually separated by intervals varying from some hours to some months; but a very grave condition supervenes (called the *status epilepticus*) when one fit succeeds another before the stage of coma has passed off. The attacks may be preceded by a distinct 'warning,' or *aura*, as it is called. These may be very short, or may permit of the patient putting himself in a position of safety before the attack comes on, or even of preventing it. The *aura* vary greatly, but in each case the same *aura* usually precedes the fits. There may be peculiar sensations, such as flashes of light, perceptions of colour, strong odours, or strange tastes or sounds, or visions of various forms, peculiar sensations running up from the fingers or toes towards the head, or sinking at the heart or at the pit of the stomach, or twitchings of groups of muscles.

(2) *Slight Forms* (Fr. *petit mal*).—These are often spoken of as 'faints,' 'turns,' 'sensations,' 'giddiness' (see VERTIGO); and, though they are as truly epileptic as the attacks above described, they are usually regarded as altogether trivial. There may be merely a momentary confusion of thought or loss of consciousness. Thus, one while in the act of speaking may suddenly stop, stare fixedly, become pale and unconscious. In a second or two he is quite himself again, and may finish the sentence he had begun, or he may make some random remark, or perform some absurd act automatically, before he comes quite round. In other cases there may be a momentary giddiness, when objects seem to rotate, or the patient himself seems to be wheeled round, and then unconsciousness supervenes. Or there may be a feeling of faintness, or a momentary twitching of one or two groups of muscles, with pallor of the face and unconsciousness.

(3) *Irregular Forms of Epilepsy*.—Dr Hughlings Jackson has investigated a form in which there are spasms of the same nature as those in the severe fit, but limited to single groups of muscles, or spreading from one group to another, while consciousness is either not lost at all, or only at a late stage in the attack. In other forms, complicated and purposelike acts may be carried out in an automatic manner, of which the patient afterwards retains no recollection. Under this category come many attacks of kleptomania, dipsomania, and many motiveless murders.

The mental condition of epileptics between the attacks varies much. In about one-third of all cases the mind seems to be unimpaired. Napoleon Bonaparte, Peter the Great, Mohammed, and Julius Cæsar are examples of epileptics with highly developed mental faculties. In the majority of cases, however, there is some defect, which may be merely a gradually increasing failure of memory, or insanity, or hopeless imbecility. Very often there is uncertainty of temper, moroseness, or criminal tendencies. The mental deterioration seems to be influenced more by the early commencement and duration of the disease, and by the frequency of the fits, than by their severity or their form. The disease may begin at any period of life, perhaps most commonly between the thirteenth and seventeenth years. The fits may occur during sleeping or waking. They are themselves rarely fatal, except by some accident, such as suffocation, burning, or injury, or when they succeed each other so rapidly that the patient does not become conscious in the interval.

The brain after death presents no appearance that can be called characteristic of the disease. In

most cases it appears typically healthy. Such abnormal conditions as are present are in most cases accidental, or the consequences of the repeated fits. In some cases thickening of the skull or of the membranes, or tumours in the brain, are present, and have by their irritation caused the fits. Probably the brain changes are too fine to be detected by our present means of research. Up till recently it was always taught that the medulla oblongata acted as the starting-point of the fits, spasm of its vaso-motor centre causing contraction of the vessels of the brain, and cutting off its supply of blood—a condition which experiment has shown to produce convulsions. Lately the view has been gaining ground that the change begins in the nerve-cells of the gray matter of the surface of the cerebrum, and that it is due to an inordinate discharge of nerve energy.

The causes of the disease are often altogether obscure. The two factors of most importance are, first, the inheritance of nervous instability from ancestors who have suffered from epilepsy or some other form of nervous disease, or who have damaged their nervous systems by alcoholic or other excess; and secondly, alcoholism on the part of the patient himself. Teething in children, fright, mental excitement, injuries to the head, or intestinal worms are not infrequent causes.

*Treatment*.—During the onset, when the *aura* is prolonged, the fit may sometimes be arrested by a bandage tied tightly round the limb along which the peculiar sensation passes, or in other cases by stimulation of the nostrils by snuff or ammonia. In such cases the appropriate remedy should be always ready at hand. During the attack there is nothing to be done except to put the patient into the horizontal position, loosen his neckcloth, and let him have plenty of air. The most severe fits usually terminate spontaneously, and any treatment beyond endeavouring to prevent suffocation is unnecessary and often injurious. After the fit is over, the patient should be allowed to sleep. In the general management of the case between the fits, a quiet, regular life, if possible in the country, with a moderate amount of physical and mental exercise, should be enjoined. The calling must be such that there is no risk to life in the event of a fit occurring. Children should be educated, but not overpressed. The dietary should be simple and digestible, with much milk, eggs, and vegetables, but without altogether excluding meat. Alcohol, coffee, and tea should be absolutely forbidden. Marriage seems to have no effect on the disease, but it must be remembered that the children of such unions are apt to suffer from nervous disease. Intern marriage of epileptics should be absolutely discouraged. With regard to the medicinal treatment, although there is no specific against epilepsy comparable to the action of quinine in malaria, the bromide compounds are the most efficacious. But it is essential to success that their use be persevered in steadily for long periods. The mistake commonly made is to use the remedy for a week or two after the attacks, and then to discontinue it till the next fit occurs. The patient should be aware that hope of cure cannot be held out to him unless he persists faithfully with the treatment. In all cases sources of irritation must be carefully sought for; their removal often serves to cure the disease. Cerebral surgery has achieved brilliant results recently in the removal of such sources of irritation to the brain as diseased bones of the skull, and even tumours in the organ itself; but operations on the brain are always such serious matters that they are not to be undertaken without due consideration of the risks run not only to life, but to usefulness of limbs, and after careful comparison of these dangers

with the benefit likely to be derived from surgical interference.

**Epilobium** (or WILLOWHERB, from its characteristic habit and silky-tufted seeds), a widely diffused herbaceous perennial genus of Onagraceæ, common in moist places. *E. angustifolium* is one of the most familiar denizens of the cottage garden, and is also common in shrubberies. In aëtic regions its young shoots are sometimes eaten in case of need, and in Kauchatka a kind of beer is made from the sugary pith. This species, with several others, is common in North America, where it is sometimes called *fire-weed*, since it often covers the scenes of great forest fires, and sometimes *slink-weed*, from a belief that it causes cows to 'slink' or misbehave. About a score of other species are occasionally seen in gardens.

**Epilogue** (Gr. *epi*, 'upon' or 'after,' and *logos*, 'a speech') means, in oratory, the summing up or conclusion of a discourse; but in connection with the drama it denotes the short speech in prose or verse which was frequently, in former times, subjoined to plays, especially to comedies, as contrasted with the Prologue at the beginning. The epilogue was always merry and familiar in its tone, and was intended to establish a kindly understanding between the actor and the audience, as well as to conciliate the latter for the faults of the play, if there were any, and to send them away in good humour. One of the neatest and prettiest epilogues ever written, and one which completely realises what an epilogue should be, is that spoken by Rosalind at the conclusion of Shakespeare's *As You Like It*.

**Epimenides**, a Greek poet and priest, sometimes included among the 'seven sages,' was born in Crete in the 7th century B.C. According to one tradition, during a sleep of fifty-seven years he received the divine inspiration which determined his future career. (Goethe wrote a poem on the subject, *Des Epimenides Erwachen*.) He was reputed to have lived for 299 years. Epimenides went to Athens about 596 B.C., where, by the performance of various mystical rites and sacrifices, he stayed a plague with which the inhabitants were afflicted, and co-operated with Solon in reforming the Athenian constitution. He was the 'prophet' quoted by St Paul in Tit. i. 12. That he wrote the epic poems attributed to him, the longest of which was on the Argonautic expedition, is considered highly improbable. Compare Schlutess, *De Epimenide Crete* (Vienna, 1877).

**Epinal**, the capital of the French department of Vosges, delightfully situated at the western base of the Vosges Mountains, on the Moselle, 46 miles SSE. of Nancy by rail. It is a clean, well-built town, surmounted by the ruins of an old castle, whose gardens are much admired. Among its buildings are the church of St Maurice, founded about 960, the museum, and a library of 28,000 volumes. Epinal manufactures cotton, paper, &c. Pop. (1872) 10,938; (1886) 18,580, an increase largely due to the influx of Alsatians.

**Epinaly**, MADAME D', a French writer, born about 1725, at nineteen married her cousin. The union proved an unhappy one, and she struck up liaisons with men of genius—first with Rousseau, for whom in 1756 she built a cottage (the now famous Hermitage) near the valley of Montmorency, and then with Grimm. She spent her last years in comparative solitude, and died 17th April 1783. Her *Conversations d'Emilie* (1774), a work on education, was crowned by the French Academy. Her *Mémoires et Correspondance* (1818) is an autobiographical romance. See ROUSSEAU; and Perey's *Jeunesse de Mme. d'Epinaly* (1882).

**Epiornis**. See *LEPYORNIS*.

**Epiphaues**. See *ANTIOCHUS*.

**Epiphanius**, a Christian bishop and writer of the 4th century, was born of Jewish parents in Palestine. He was educated among the Egyptian monks, who imbued his mind at once with a fervent piety and an intolerant bigotry that together led him in after-life into most unchristian excesses. He rose gradually to the rank of Bishop of Constantia (formerly Salamis) in Cyprus, and continued in that office from 367 till his death in 403. His polemical zeal was conspicuously manifested against Origen. He had proclaimed him a heretic in his writings, and in 394 he went to Palestine, the stronghold of Origen's adherents, and called upon John, Bishop of Jerusalem, to condemn him. Both in this instance and in his conduct to Chrysostom afterwards, he displayed a tyrannical and intolerant passion. Among his writings, collected by Petavius (2 vols. Paris, 1622), the most important is his *Panarion*, or catalogue of all heresies (80 in number), a work which strikingly shows his unfitness for the task of a historian. See a monograph by Lipsius (Vienna, 1865).

**Epiphany** (Gr. *Epiphaneia*, 'manifestation') denoted, among the heathen Greeks, the appearance of a god to a worshipper. The word was subsequently used to designate the manifestation or appearance of Christ upon earth to the Gentiles, with especial reference (in the Western Church) to his adoration by the Magi (q.v.). This occasion is commemorated on 6th January, the 12th day after Christmas, and hence the Epiphany is also called Twelfth Day (q.v.). Until the latter end of the 4th century, the 6th January was a festival in honour of Christ's nativity and baptism. See *BEFANA*.

**Epiphytes** (Gr. *epi*, 'upon,' *phyton*, 'a plant'), often and popularly, but less correctly, called Air-plants, are plants which are not rooted in the ground, but are attached to trees, &c. Mosses and lichens themselves, growing upon trees, may be called epiphytes, but the term is generally used of phanerogamous plants. It is chiefly in warm and moist climates that phanerogamous epiphytes are found, and in those which are also moist, although many exhibit considerable endurance of drought. Most of them prefer shady situations. Within the tropics, they often form an interesting and remarkable feature of the vegetation. Some of the Bromeliaceæ (as *Tillandsia*), Cactaceæ, Araceæ, Gesneriaceæ, and other orders are epiphytes; most frequently, however, the Orchidaceæ. See *ORCHIDS*, *TILLANDSIA*, &c.; and Kerner's *Pflanzenleben*.

**Epirus** ('mainland'), the ancient name of a part of Greece, extending between Illyria and the Ambracian Gulf, and from the Ionian Sea to the chain of Pindus. It was a wild and mountainous region, heavily wooded, and producing but little corn, though celebrated for its cattle and horses, and for its breed of Molossian dogs. The principal rivers were the Aous, Arachthos, Thyamis, and Acheron (q.v.); the chief towns, Dodona (q.v.) and Ambracia (q.v.). Anciently, as to-day, the inhabitants were only half Hellenic, the Greek colonies being confined to the coast and southern portion. Of the Molossian kings of Epirus, the most famous is Pyrrhus (q.v.), who long waged successful war against the Romans. On the conquest of Macedonia by the Romans (168 B.C.), the most revengeful measures were put in force against the Epirotes, who had assisted Perseus, the Macedonian king. Æmilius Paulus, the Roman general, plundered and razed to the ground seventy towns of Epirus, and sold into slavery 150,000 of the inhabitants. From this period, Epirus shared the vicissitudes of the Roman and Byzantine empires,

until 1204, when one of the Comneni made himself independent. Petty princes ruled the country until the 15th century, when it was finally conquered by the Turks (see SCANDERBEG). Epirus was peopled largely since the 14th century by Albanians (see ALBANIA), formed latterly a part of the Turkish vilayet of Janina. Under pressure from the great powers, Turkey ceded the strip of territory east of the river Arta to Greece in 1831.

**Episcopacy.** See BISHOP.

**Episcopius, SIMON** (properly *Biscop*), the leader of the Arminian party after the death of its founder, was born at Amsterdam in 1583, and studied (from 1600) at Leyden. Arminius and Gomarus were his teachers in theology, and on the death of the former in 1609 Episcopius was obliged, on account of his known attachment to Arminius' views, to leave Leyden for Franeker. In 1610 he became pastor at Bleysswich, a village near Rotterdam, and in the following year he was one of five 'Remonstrants' appointed by the government to meet five 'Contra-Remonstrants' at a conference at the Hague. When Gomarus resigned his chair at Leyden, Episcopius was appointed his successor (1612). Called with twelve other Arminian theologians to the bar of the Synod of Dort (1618), Episcopius (with the rest) was condemned and banished from the country. He removed to the Spanish Netherlands, where he wrote his famous *Arminian Confessio* (published in 1622). On the renewal of the war between Spain and Holland, he found refuge in France, where he lived mostly at Paris and Ronen, and published a series of able controversial treatises. Permitted in 1626 to return to his native country, he was for several years a preacher at Rotterdam, where he wrote his *Apologia pro Confessione* in 1629. From 1634 he was professor at the Arminian College at Amsterdam, and here he produced his *Institutiones theologicæ* and *Responsio ad Questiones Theologicæ*, two works which are mutually complementary, and which, though the former was left incomplete at his death in 1643, present an ample apology not only of Arminian theology, but of the Christian revolution itself. Episcopius everywhere lays the utmost stress on the personal responsibility of man in relation to divine grace, denies the doctrine of original sin, and treats Christian faith not as a doctrinal theory, but as the potentiality of right moral conduct. Yet it cannot be denied that, in his view of the Trinity, the Son and the Holy Spirit are partakers of divine power and glory *non collateraliter sed subordinatè*, and that he held it enough to believe that the Holy Spirit proceeds only from the Father, and is the spirit of the Son. This rationalistic development of Arminian doctrine by Episcopius went far beyond the famous Five Articles of 1610, but in the next generation was generally adopted by the Arminian party. His works were collected in 2 vols. (Amst. 1650-65). The best life is Philip Limborek's *Historia vitæ Simonis Episcopii* (Amst. 1701). See ARMINIUS, CALVINISM; and Sepp, *Het godgeleerd onderwijs in Nederland* (1873).

**Epistles.** See BIBLE.

**Epistolæ Obscurorum Virorum** ('Letters of Obscure Men') is the title of a collection of satirical letters which appeared, in dog-Latin, at the commencement of the 16th century, and professed to be the composition of certain ecclesiastics and professors in Cologne and other places in Rhenish Germany. They were directed against the scholastics and monks, and lashed with merciless severity their doctrines, writings, morals, modes of speech, manners of life, follies, and extravagances, and thus helped in no small degree to bring about the Reformation. The con-

troversy of Renellin with the baptised Jew, Pfefferkorn, concerning Hebrew books, gave the first occasion to the *Epistolæ*, and it is probable that their title itself was suggested by the *Epistolæ Clarorum Virorum ad Reuchlinum* (1514). On the first appearance of the work, it was fathered on Renellin; afterwards it was ascribed to Renellin, to Erasmus, and to Hutten. By many it has been held that Hutten was the chief author, and Crotus Rubianus his chief assistant in the work, which appeared at Hagenau in 1516 (but professedly at Venice). But though Hutten certainly wrote the letters which appeared in 1517 as a second part of the *Epistolæ Obscurorum Virorum*, it cannot be said to have been proved that he had any share in the first part, of which Crotus Rubianus would accordingly be the chief author, as he certainly was the suggester of the scheme. The circumstance of the *Epistolæ* being placed in the *Index Expurgatorius* by a papal bull helped to spread it not a little. Among the numerous editions of the work, the best is Böcking's, with commentary, in his edition of Hutten's works (1869). See D. F. Strauss's *Ulrich von Hutten* (Eng. trans. 1874), and Mark Pattison's *Essays* (2 vols. 1889).

**Epitaph** (Gr. *epi*, 'upon,' and *tephos*, 'a tomb'), any commemorative inscription upon a monument. Naturally, brevity and point are the principal things to be aimed at in such memorials, and, as the elemental human emotions are ever the same, we find a striking similarity between ancient and modern epitaphs. The oldest we have are those of the Egyptians, written on the sarcophagi, but these are brief and formal, being merely a record of the name and condition of the deceased, with a prayer to Osiris or Anubis. Quite different are the early Greek epitaphs, which often both in form and substance evince fine literary skill. The earlier examples are mostly in elegiac verse. None are better than those of heroes who have fallen in battle, and of these the classical example is that on the three hundred martyrs to patriotism at Thermopylæ, ascribed to Simonides:

Go tell the Spartans, thou that passest by,  
That here obedient to their laws we lie.

The Roman epitaphs usually contain a more or less bare record of facts. On the urns the letters D. M. or D. M. S. (*Dis Manibus or Dis Manibus Sacrum*) are usually followed merely by the name of the deceased, his age, and condition, with the name of the person who caused the urn to be made. These characters were often adopted from mere conservatism by Christians, and we find them conjoined with purely Christian sentiments in the catacombs at Rome. The ashes of the dead were usually placed along the sides of the great highways leading into Rome, hence the appropriateness of the common commencement, *Siste Viator*—the 'stop passenger' to be seen in so many of our English churchyards. One feature not uncommon in Roman inscriptions was an exhortation upon the disturber of the sepulchre—the reader will remember that on Shakespeare's tomb at Stratford-on-Avon, most probably from the pen of the great dramatist himself.

Long after the Roman empire had crumbled into ruins, the Latin tongue continued to be used for inscriptions, but in England we occasionally find French used as early as the 13th century. It was hardly, however, till the time of Elizabeth that epitaphs became really literary; then and after we find them written in admirable epigrammatic form by Ben Jonson, Milton, and many others. Pope's English epitaphs were long famous, and also those by Dr Johnson in Latin. The latter's answer to the famous round-robin signed by Gibbon, Burke, Sir Joshua Reynolds, Sheridan, Warton, and others,

requesting that he should write the epitaph for Goldsmith in English, was that 'he would never consent to disgrace the walls of Westminster Abbey with an English inscription.' It is no doubt true that no language lends itself so well to dignity in brief simplicity as the Latin, but the argument from its stability and universality becomes weaker with every generation.

The naturally epigrammatic turn of the French mind peculiarly adapts it for the epitaph, and in French collections very felicitous examples are to be found both in Latin and in French, such as the 'Tandem felix!' of the Count de Tena; the touching epitaph to a mother, 'La première au rendez-vous;' and that written by Piron for himself after his rejection by the Academy:

Ci-gît Phom, qui ne fut jamais rien,  
Pas même Académicien.

A large number of the earlier monuments, and consequently of the epitaphs of this country, were destroyed by unfortunate iconoclastic zeal at the Reformation, and after the triumph of the Puritan revolution. The epitaphs to be found in our parish churchyards display every variety of taste, from pure pathos, simplicity, and dignified eulogy to painful would-be wit and even vulgar buffoonery.

See Weever's *Ancient Funerall Monuments* (1631; ed. by Tooke, 1767); Philip Labbe, *Theatrum Epitaphiorum* (Paris, 1666); De la Place, *Recueil d'Epitaphes* (3 vols. Paris, 1783); Pettigrew's *Chronicles of the Tombs* (1857); Northend, *Book of Epitaphs* (New York, 1873); J. R. Kippax, *Churchyard Literature: a Choice Collection of American Epitaphs* (1876); and W. Andrews, *Curious Epitaphs* (1883).

**Epithalamium**, a species of poem which it was the custom among the Greeks and Romans to sing in choros near the bridal-chamber (Gr. *thalamos*) of a newly-married pair. Sappho, Anacreon, Stesichorus, and Pindar composed poems of this kind, but only scanty fragments have been preserved. The epithalamium of Peleus and Thetis by Catullus is one of the finest specimens of Latin poetry extant; but probably the most splendid epithalamium in all literature is that of our own poet Spenser. Latin examples are extant by Statius, Ausonius, Claudianus, and other poets. A collection of Latin epithalamia is to be found in Wernsdorf's *Poetae Latini Minores* (4th vol. part 2, Helmst. 1789).

**Epithelium** is the term applied in anatomy to the cell-tissue which, in layers of various thickness, invests not only the outer surface of the body, and the mucous membranes connected with it—as, for example, those of the nose, lungs, intestinal canal, &c.—but also the closed cavities of the body, such

the position in which it occurs. In some parts it consists of numerous strata of cells, collectively forming a layer of more than a line in thickness; in other parts it is composed of only a few strata, or often of only a single stratum of cells, and can only be detected by the microscope. The cells of which the epithelium is composed are usually soft nucleated cells; they may be rounded, polygonal, fusiform, cylindrical, or conical in shape, and sometimes they possess vibratile cilia. No blood-vessels exist in epithelial tissues, although minute channels may be found between the cells, by means of which the plasma derived from subjacent blood-vessels may pass for the nutrition of the cells. In many cases nerve fibrils are abundant.

Fig. 3.

Epithelium of the intestinal villi of the rabbit. Mag. 300 diam.

Epithelia may be classified (*a*) according to the embryonic layer from which they are developed; (*b*) according to their function; (*c*) according to their shape and arrangement. Following the latter method, we have (*a*) *simple epithelium*, consisting of a single layer of cells which may be: (1) *Pavement*, consisting of polygonal plates or scales joined together by their edges. They constitute the variety known as pavement or tessellated epithelium, and occurring as an investment of the serous membranes, of most synovial membranes, of the lining membrane of the heart and of the veins, of the canals of glands, &c. (2) *Columnar or cylinder epithelium*, as in the intestine from the stomach to the termination of the alimentary canal, in the excretory ducts of all the glands opening into the intestine, &c. Illustrations of this cylinder epithelium are given in the article

Fig. 4.

Ciliated cells from the finer bronchial tubes. Mag. 350 diam.

**DIGESTION.** (3) *Spheroidal or glandular epithelium* is chiefly characteristic of the terminal recesses of secreting glands. (4) *Ciliated epithelium* consists of cells which bear on their free ends spontaneously moving filaments called *Cilia* (q.v.). (5) *Stratified epithelium* consists of cells arranged in many layers, and the individual cells present every variety of shape. As a rule the deepest cells are columnar, and those on the surface flattened and scale-like, but overlapping one another at their margins. It occurs on the anterior

Epidermis (still soft like the epithelium of internal parts) of a two months' human embryo. Mag. 350 diam.

Fig. 2.

Epithelial cells of the vessels; the longer one from the arteries, the shorter ones from the veins.

Fig. 5.

Stratified pavement epithelium investing a simple papilla (with blood-vessels in the interior) from the gums of a child. Mag. 250 diam.

as the great serous membranes, the ventricles of the brain, the synovial membranes of joints, the interior of the heart and of the blood-vessels proceeding to and from it, the ducts of glands, &c. The thickness of this tissue varies extremely with

as the great serous membranes, the ventricles of the brain, the synovial membranes of joints, the interior of the heart and of the blood-vessels proceeding to and from it, the ducts of glands, &c. The thickness of this tissue varies extremely with

surface of the cornea of the eye, in the mouth, pharynx, œsophagus, &c., but its most extensive distribution is in the Epidermis (q.v.). (c) *Transitional epithelium* is intermediate between the forms already described, and may be grouped under the three terms columnar, ciliated, and scaly transitional, according to the kind of cell which is most superficial. In the case of the columnar and ciliated varieties there are smaller cells irregularly disposed between the fixed ends of the large ones, and this constitutes the only difference between these and the columnar and ciliated cells already described.

Scaly transitional epithelium is found lining the urinary Bladder (q.v.) and ureters. The superficial cells are flattened scales when the bladder is distended, but cubical when empty. Moreover, the free surface of the cells is smooth, but on the deep aspect they are moulded over the rounded ends of the pear-shaped cells beneath. Irregular cells fill up the intervals between the tapering ends of the pyriform cells.

Fig. 6.

Ciliated epithelium from the trachea of a man. Mag. 350 diam. a, outermost part of the elastic longitudinal fibres; b, homogeneous outermost layer of the mucous membrane; c, deepest round cells; d, median long cells; e, outermost conical ciliated cells.

In all the varieties of epithelium the layer of external cells is being constantly disintegrated and replaced by the layer immediately beneath. The polygonal or pavement epithelium mainly acts like the epidermis, as a protecting medium to the soft parts beneath. The cylindrical epithelium additionally takes an active part in the process of secretion. Illustrations of the function of the cells forming this variety of epithelium are given in the articles CELL, CILIA, DIGESTION; and the subject will be further noticed under the head SECRETION.

**Epizoa**, animals that live on the bodies of other organisms in various degrees of parasitism. See PARASITISM, BUG, FLEA, LOUSE, MITE, TICK, &c.

**Epizootics** (Gr. *epi*, 'upon,' and *zōon*, 'an animal') are diseases of animals which manifest a common character, and prevail at the same time over considerable tracts of country. A curious circumstance in connection with them is that they usually follow the same line of route as the diseases of the human race; and, as a rule, when there has been a great epidemic, it has been followed or accompanied by an equally destructive pestilence among animals. The cause of epizootics is not altogether clear, but there can be little doubt that insufficient food and overcrowding have great influence. Being apt to take on a low type of fever, they are better treated by supporting than by reducing remedies. Influenza in horses, and pleuro-pneumonia and vesicular epizootic in cattle, are examples.

**Epoch**, in Astronomy, is an abbreviation for 'longitude at the epoch;' it means the mean heliocentric longitude of a planet in its orbit at any given time—the beginning of a century, for instance. The epoch of a planet for a particular year is its

mean longitude at mean noon, on January 1, when it is leap-year, and on December 31 of the preceding year, when it is a common year. The epoch is one of the elements of a planet's orbit. For epoch in chronology, see CHRONOLOGY.

**Epode** is the last part of the chorus of the ancient Greeks, which they sung after the strophe and antistrophe, when the singers had returned to their original place. The name was applied also to a species of lyric poem invented by Archilochus, in which a longer verse is followed by a shorter one, as the *Epodes* of Horace. See CHORUS.

**Eponym** (Gr. *epi*, 'on,' and *onyma*, 'a name'), a mythical personage created to account for the name of a tribe or people; thus Tros is the eponymous hero of Troy, Italus was assumed as ancestor of the Italians, &c. For the Assyrian eponym canon, see ASSYRIA.

**Epping**, a market-town of Essex, in a pleasant healthy situation, at the north end of Epping Forest, 16 miles NNE. of London. It is noted for its cream, butter, sausages, and pork. Pop. of parish, 2343.—Epping (formerly Waltham) Forest, where kings hunted in olden days, once covered all Essex, and extended almost to London. Inclosures gradually curtailed it from 60,000 acres to 12,000 in 1793, and to less than 4000 in 1871, when (the government refusing to stir in the matter) the corporation of London undertook the preservation of all that was left, and the recovery of the more recent inclosures. As an outcome of their exertions, and at a cost of about half a million of money, 5600 acres of Epping Forest were declared free to the public by the Queen on 6th May 1882. Reached easily from Loughton, Clingford, and other stations, Epping Forest is still a glorious place alike for naturalist and mere holiday-maker. Its 9 square miles of almost unbroken woodland, which at High Beech or Queen Victoria's Wood attain a height of 759 feet above sea-level, form one of the most extensive and beautiful pleasure-grounds in Europe. Separated by a stream from Epping Forest is Hainault Forest (the 'garden fair' of Mr Besant), which was disafforested in 1851. Here, till 1820, stood Fairlop Oak, the scene of a July fair, as famous in its way as the old Epping stag-hunt on Easter Monday. See E. N. Buxton, *Epping Forest* (1884); and W. R. Fisher, *The Forest of Essex* (1887).

**Eprouvette** is a machine for proving or testing the strength of gunpowder. The *gun* eprouvette does this by measuring the amount of recoil produced on a small gun swung like a pendulum; the *mortar* eprouvette by measuring the distance to which a ball is projected. A third pattern is shaped like a small pistol, with an extremely short barrel, closed by a flat plate connected with a strong spring. On firing, the plate is driven back to a distance indexed according to the strength of the powder.

**Epsom**, a small market-town of Surrey, on the margin of the Banstead Downs, 15 miles SSW. of London. The sulphate of magnesia springs, which made Epsom so fashionable a resort in the later half of the 17th century, gave name to the Epsom salt formerly manufactured from them. The church, rebuilt in 1824, contains monuments by Flaxman and Chantrey. The Royal Medical College (1851), on the Downs, provides education for the sons of medical men, and affords a home to decayed members of the profession and their widows. Pop. (1841) 3533; (1881) 6916. On the Downs, 1½ mile S. of the town, the famous horse-races are held yearly (see DERBY DAY, and HORSE-RACING). The grand stand was built in 1829–30, at a cost of £20,000, and accommodates 7500 spectators.

**Epsom Salt**, or SULPHATE OF MAGNESIA,  $MgSO_4 \cdot 7H_2O$ , was originally obtained by evaporating the waters of the springs at Epsom. It was soon found that sea-brine also contained large quantities, and the manufacture at Epsom was therefore given up. At present it is found native in various parts of America, and large quantities are manufactured near Genoa, by a chemical process, from a rock containing magnesite and sulphide of iron. In England, as well as in America, varieties of magnesian limestone are extensively treated with sulphuric acid for its production, with the result that the market is well supplied with this useful remedy.

Epsom salt forms small needle-like crystals, which have a bitter saline taste and neutral reaction. It is a well-known useful purgative medicine, acting as a refrigerant, and sometimes as a diuretic. Its disagreeable bitter taste may be relieved by the addition of a little sulphuric acid (as in Henry's solution) or syrup of lemon. It is given in doses of  $\frac{1}{2}$  oz. to 1 oz. or more, but in every case it is of importance that plenty of water be drunk along with it (one or more tumblerfuls). See MAGNESIUM.

**Epworth**, a market-town of Lincolnshire, in the 'Isle' of Axholme, 10 miles NNW. of Gainsborough. The great John Wesley was a native, as well as Alexander Killiam, founder of the Methodist New Connection. Pop. of parish, 2178.

**Equations.** The statement in symbols of the relationship of equality existing between two algebraic expressions is termed an equation. Such expressions generally contain at least one unknown quantity. Thus  $x - 2 = 4 + 3$  is an equation denoting that if 2 be deducted from some unknown quantity denoted by  $x$ , the remainder will be equal to  $4 + 3$ , that is 7; therefore the value of  $x$  in this equation is evidently  $7 + 2$ , or 9. Any equation in one variable  $x$  may be reduced to a form such as  $F(x) = 0$ , where  $F(x)$  is a function of  $x$ , and this may be considered as the standard form of all equations. When written fully in the most general manner, this may be said to be equivalent to the equation

$$a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_{n-2}x^2 + a_{n-1}x + a_n = 0.$$

This is said to be an equation in  $x$ , the variable involved;  $a_0, a_1, a_2, \dots, a_n$  are the coefficients, either numerical or algebraical quantities. Any quantity which, when substituted for  $x$ , reduces the left-hand side to zero—i.e. any quantity which satisfies the equation, is termed a *root* of the equation. The main problem in equations is that of finding all the possible roots; this done, a *complete solution* is obtained. The theory of equations is a most important branch of algebra.

*Identical* equations are those which are always true, whatever be the value of the quantities involved; *conditional* equations are satisfied only by certain values for  $x$ . Equations are usually classified according to their *degree*, which is defined as being the highest degree of the involved variable. The equation written above as the standard form is, for example, of the  $n$ th degree. Simple equations, or equations of the first degree, are those in which  $x$  or the unknown quantity appears only in the first power; when  $x$  appears in the second power, the equation is quadratic; when  $x$  is in the third power, cubic, and so on. Equations of the first, second, third, fourth, fifth, &c. degrees are sometimes called linear, quadratic, cubic, quartic (or biquadratic), quintic, &c. equations. See Burnside and Panton, *Theory of Equations* (1881); Todhunter's treatise on the same subject (new ed. 1880); or Chrystal's *Algebra*, part i. chaps. 14-19.

Equation in astronomy means the corrections or

reductions which must be applied to observations in order either to free them from error or otherwise to reduce them to some form more suitable for purposes of calculation. For the *Equation of Time*, see the article DAY. *Personal equation* is a correction which has to be applied to astronomical (or other) observations in order to remove relative error due to some peculiar mode of observation on the part of the observer. In astronomical observatories it is the practice to find this personal equation for all the observers with reference to one single observer, and the observations are all reduced by its application, so that finally they are tabulated as if made by one observer. The phrase has passed into common language, and is often used to denote that modification which is requisite in the statements or judgments of any person who in such matters is not free from bias or idiosyncrasy. There are also *equations to the centre*, allowing for the difference between the place of a planet as supposed to move in a circle and its actual place in an ellipse; and *equations of equinoxes*, between mean and apparent equinoxes. *Equation of payments* is an arithmetical rule for ascertaining at what time it is equitable for a person to pay a whole debt which is due in different parts, payable at different times. Equations are constantly used in Chemistry (q.v.).

**Equator.** The Terrestrial Equator is the great circle on the earth's surface dividing the earth into the northern and southern hemispheres, and halfway between the poles.—The Celestial Equator is the great circle in the sky corresponding to the extension of the equator of the earth.

**Equatorial**, an important instrument for observing and following a celestial body in any part of its diurnal course. It consists, in the usual form, of two axes, one fixed square across the end of the other, thus  $\perp$ . The cross axis (called the *declination axis*) revolves in bearings fixed to the upright one (called the *polar axis*), which again turns in bearings supported by a fixed pillar, resting on a solid foundation. Across one end of the cross axis is rigidly fixed a telescope, and on the other end slides a counterbalancing weight. Thus the telescope can be turned freely in any direction, and clamped by suitable mechanism. As erected for use, the upright axis is fixed to point directly to the pole of the heavens. It being then revolved, the other axis will trace with its ends the line of the celestial Equator (q.v.). By this motion the telescope sweeps the sky from east to west, and by rotating the cross axis it sweeps from north to south. The amount of rotation of each axis is measured by a graduated circle fixed to it, and thus the position of any heavenly body observed is known. Conversely, by setting the circles and observing the time, the telescope may be set so as to point to any star, even if it be one invisible to the naked eye. The hour circle, on the polar axis, measures the right ascension of the star, and the other, or declination circle, its declination. The equatorial can hardly be called an astronomical instrument. It is rather a convenient method of mounting large astronomical telescopes. For if the telescope be pointed to any star and clamped, while the *polar axis* is regularly revolved by clockwork, the star remains steadily in the field of view. See TELESCOPE.

**Equerry**, in the household of British sovereigns, is an official in the department of the Master of the Horse (q.v.), whose main duty is to accompany the sovereign when riding in state. The royal princes have also equeries.

**Equestrianism.** See RIDING.

**Equestrian Order**, or EQUITES. This body originally formed the cavalry of the Roman army,

and is said to have been instituted by Romulus, who selected from the three principal Roman tribes 300 equites. This number was afterwards gradually increased to 3600, who were partly of patrician and partly of plebeian rank, and required to possess a certain amount of property. Each of these equites received a horse and 'barley-money' from the state; but about 400 B.C. a new body of equites began to make their appearance, who were obliged to furnish a horse at their own expense, although they received regular pay. These were probably wealthy *novi homines*, men of equestrian fortune, but not descended from the old equites. Until 123 B.C. the equites were exclusively a military body; but in that year a measure was carried transferring the judicial functions from the senate to the equestrian body, which now became a distinct order or class in the state, and was called *Ordo Equestris*. In 70 B.C. Sulla deprived them of these powers; but their influence did not then decrease, as the farming of the public revenues had fallen into their hands; and after Sulla's death they shared their former privilege with the senate. Under the emperors, when the requisite fortune of an eques seems to have been about £3230, the state still furnished horses for what was no longer the national cavalry; but as the honour, indiscriminately conferred, fell into contempt, foreign auxiliaries took the place of the old knights, and the body gradually became extinct.

**Equidæ.** See HORSE.

**Equilibrium,** the state of rest or balance of a body or system, solid or fluid, acted upon by various forces. See STATICS, and HYDROSTATICS.

**Equinia.** See GLANDERS.

**Equinoctial** is the same as the celestial Equator (q.v.). The equinoctial points are those in which the equinoctial and the Ecliptic (q.v.) intersect. Equinoctial time is time reckoned from the moment in each year when the sun passes the Vernal Equinox (see EQUINOXES). This instant is selected as a convenient starting-point of a uniform reckoning of time for the purposes of astronomical observations.

**Equinoctial Gales.** One of the most widespread beliefs in, at least, the British Islands is that there occurs an unusual frequency of gales and storms about the times of the spring and autumn equinoxes. This belief is, however, unsupported by the records of carefully conducted observations. Thus at Gordon Castle, in Strathispey, upwards of fifty years' observations show, on the contrary, fewer storms on the five days from the 21st to the 25th of March and September than on the five days preceding and the five days following these dates. Long-continued observations at other places are equally decisive against the popular belief.

**Equinoxes.** Sometimes the Equinoctial Points (see EQUINOCTIAL) are called the equinoxes. More commonly, by the equinoxes are meant the times when the sun enters those points—viz. 21st March and 22d September, the former being called the Vernal or Spring Equinox, and the latter the Autumnal. When in the equinoxes, the sun, through the earth's rotation on its axis, seems to describe the circle of the equator in the heavens, and the days and nights are of equal length all over the world. At the vernal equinox, the sun is passing from south to north, and in the northern hemisphere the days are lengthening; at the autumnal, he is passing from north to south, and the days are shortening. As the earth moves more rapidly when near the sun, or in winter, the sun's apparent motion is not uniform, and it happens that he takes eight days more to pass from the vernal to the autumnal equinox than

from the latter to the former. The equinoctial points are not stationary. See ECLIPTIC, PRECESSION.

**Equisetaceæ.** See HORSE-TAIL.

**Equity, EQUITABLE RIGHTS, &c.** Equity (Lat. *æquitas*) signifies moral justice, of which laws are the imperfect expression; or the spirit of justice which enables us to apply and interpret laws rightly. Thus, the equity of a statute means the fair and wise construction of it, according to the intention of parliament, as distinguished from the literal and technical construction of the words used. It is impossible that any system of positive law should provide a rule suited to every case that arises; even good laws may work injustice, unless they are interpreted by men having discretion and authority to control their rigour and supply their deficiencies. In the Old Testament and in the New, we constantly meet with the distinction between form and substance, between the letter which killeth and the spirit which maketh alive. The early Roman law was, like that of Moses, a system of forms and ceremonies; but the prætors, who had jurisdiction in commercial cases, soon found it necessary to go beyond the limits of custom and tradition. They assumed the *nobile officium* of deciding in accordance with equity; and their decisions formed the *jus honorarium* (magistrate's law, as distinguished from the customary law of the people). Courts of equity do not exercise an arbitrary discretion; they proceed on principles. The prætor, on entering upon his office, published an edict, setting forth the principles by which his judicial conduct would be guided; and as each prætor naturally adopted what was sound in the edicts of his predecessors, a system of equity was gradually developed. Ultimately, in the reign of Hadrian, the edicts of the prætors were consolidated in a single document called the *Perpetual Edict* (see EDICT).

In England, all the courts apply equitable principles in construing statutes and formal instruments; but the form equity has acquired a peculiar importance, by reason of the part which the Court of Chancery (q.v.) took in supplementing and controlling the rules of the common law. The common lawyers protested against the arbitrary nature (as it seemed to them) of equitable jurisdiction; they said that equity meant only the length of the chancellor's foot. But before the end of the 17th century this reproach was removed; the rules of equity were reduced to a system; and the Chancery jurisdiction was firmly established. The powers of the court were of three kinds: 1. Exclusive, as in the administration of trusts. When the legal ownership of property was conveyed to a trustee, he was the only person whom a court of law could recognise as owner; but a court of equity would protect the equitable estates of the persons beneficially entitled (see TRUST and USE). 2. Concurrent, in cases where law and equity both provided a remedy. Thus, in a case of breach of contract, the law would give damages to the party wronged; but equity could, in a proper case, go further, and compel specific performance of the contract. 3. Assistant, where equity only interfered to make legal process more effective. Courts of law, for example, formerly refused to allow a party to be called as a witness; a court of equity would order a party to make discovery to his opponent of such facts as the opponent had a right to know.

The principles of equity, as applied by the Court of Chancery, are summed up in certain maxims of wide significance: 'Equity follows the law'—i.e. equity will not set aside a rule of law (such as the rule of primogeniture), but will seek to apply

existing rules in a spirit of justice. 'Equity assumes that to be done which ought to be done;' when, for example, a man sells his land, equity treats the purchaser as owner, even before the formal conveyance has been executed. When a man deposits the title-deeds of his land with a banker, in consideration of a loan, this is a good Equitable Mortgage; the borrower is not allowed to plead the absence of a written agreement as an excuse for withdrawing from the transaction; equity will even compel him to execute a formal mortgage, if the lender requires it. 'Equity looks to the substance, and not to the form;' a legal mortgage of land, for example, is, in form, an absolute conveyance; but equity treats it as a security for money. The mortgagee is legal owner; but the mortgagor retains his Equity of Redemption—i.e. his right to have the estate again on paying principal and interest of the loan. 'He who seeks equity must do equity'—e.g. a mortgagor seeking to redeem must pay off all incumbrances held by the mortgagee who has the legal estate.

It is difficult to overestimate the advantages gained by the application of equitable principles to the law of property and contract. But these advantages were counterbalanced in England by the defects of Chancery procedure, and the inconvenience caused by the existence of two sets of courts, applying different rules to the same subjects. Chancery reform has now removed the scandals of the old system. Equitable powers were conferred on the courts of common law by Acts for the improvement of procedure. Finally, the Judicature Acts, which came into force in 1875, effected a fusion of law and equity, so that in every branch of the Supreme Court equitable claims may be made, and equitable defences pleaded. Law and equity are administered concurrently; where they conflict, the rules of equity prevail. Certain classes of business, relating to trusts, mortgages, property of infants, &c., are reserved to the Chancery Division of the High Court of Justice.

In America, and in the British colonies, the distinction between law and equity is or has been recognised as in England. In Scotland, the *nobile officium* of the Roman prætor is exercised by the Court of Session. For an outline of the English system, see Snell's *Principles of Equity*.

**Equivalents**, in Chemistry. See ATOMIC THEORY.

**Era**. See CHRONOLOGY.

**Eradicated**, in Heraldry, is said of a tree, or part of a tree, torn up by the roots.

**Erard**, SÉBASTIEN, French musical instrument-maker, chiefly famous for his improvements and inventions in connection with the pianoforte and harp, was born at Strasburg on 5th April 1752. Proceeding to Paris when sixteen, he shortly afterwards started business as a pianoforte-maker in that city, constructing his first pianoforte, one of the earliest made in France, in 1776 or 1777. The outbreak of the Revolution drove him to London; but in 1796 he returned to Paris. From 1808 to 1812 he was again in London. He died near Passy on 5th August 1831. He was the inventor of the harp with double pedals, and he also improved the sound-body of the instrument. The pianoforte with double escapement was likewise invented by Erard.

**Erascd**, in Heraldry, signifies violently plucked or torn off, and showing a ragged edge; as opposed to couped or cut, which shows a smooth edge. The term is chiefly applied to the heads and limbs of animals.

Erased.

**Erasi'stratus**, one of the most famous physicians and anatomists of ancient times, was born in the island of Ceos about 300 B.C., settled in Alexandria, and died in Asia Minor. He founded a school of medicine, wrote several works on anatomy—in which branch he was most celebrated—on practical medicine, and pharmacy. He believed that the heart was the origin both of the veins and arteries. Of his numerous writings only some obscure fragments and titles have been preserved. See the article ANATOMY; and Hieronymus, *Erasi'strati et Erasistrateorum Historia* (Jena, 1790).

**Erasmus**, DESIDERIUS, was born at Rotterdam, probably in the year 1467, the date given on the pedestal of his statue in his native town. A reference in his own works, however, as also his epitaph at Basel, assigns the date 1466. He was the son of one Gerhard, and Margaret, the daughter of a physician. As of illegitimate birth, he had no surname; and the name by which he is known, Desiderius Erasmus, is but the rendering in Latin and Greek of Gerhard ('the beloved'). Erasmus first attended school at Gouda, but while still a mere child he was sent to Utrecht, to fill a place in the choir of the cathedral of that city. He was next removed to a famous school of that time—that of the 'Brothers of the Common Life,' at Deventer, where, by his own account, he was exercised mainly in composing, repeating, and learning the silliest Latin verses. The study of Greek had as yet made but slight progress out of Italy; but Erasmus was fortunate in receiving some little instruction in that language from Alexander Hegins, the head of Doventer school, and a scholar of considerable reputation. An outbreak of the plague, of which his mother died, led to his quitting this school and retiring to Gouda, the residence of his father. Gerhard dying soon after, Erasmus and his only brother were left to the care of three trustees, who grossly neglected their charge. One of the three was bent on the brothers' entering a monastery, and with this in view, instead of sending them to a university, for which they were now ripe, placed them at another school of the Brothers of the Common Life at Bois-le-Duc. Again the plague drove Erasmus to Gouda, where his guardians tried every means to persuade him and his brother to become monks. As a compromise, Erasmus agreed to enter the Augustinian college of Sion, near Delft, on the condition that it should be left to him to leave the college if he saw fit. Here, accordingly, for the next six years he lived the life of a monk, though in his case the discipline was somewhat relaxed in the hope of his being induced eventually to adopt the monastic life. It was undoubtedly this personal experience of the ways of living and thinking of the monks that made Erasmus their relentless and lifelong enemy.

Deliverance at length came to him from the Bishop of Cambrai, who engaged him as his private secretary, and undertook to provide him with means to prosecute his studies. A few months later, and after having taken priest's orders, Erasmus went to Paris, supplied, though not over-liberally, with funds by the bishop. The Collège Montaign, where he pursued his studies, was notorious among all the colleges of Paris for the severity of its discipline, the scantiness and wretchedness of its fare, and the general squalor of its domestic arrangements. The new studies of the Renaissance had as yet made but little way in Paris; but Montaign above every other college was still fast in the bonds of scholasticism. To Erasmus, therefore, whose constitution was delicate to fragility, and who from the very outset seems to have been awake to the intellectual revolution that had come upon Europe, all his surroundings in

Paris at this time were in the highest degree distasteful. To the end of his life he never forgot his experiences at Montaigu; and not the least important of his subsequent achievements was the service he did in helping to discredit the frivolous dialectic which he had there seen in its most absurd form.

With the exception of a visit to the Bishop of Cambrai on account of his health, Erasmus resided mainly in Paris till 1498, gaining a livelihood by instructing private pupils. Of these pupils, Lord Mountjoy deserves special mention, as he always remained one of Erasmus's best friends and most generous patrons. It was on the invitation of Mountjoy that Erasmus, probably in 1498, paid his first visit to England. This visit is one of the most important epochs in the life of Erasmus. Oxford was the chief place of his residence, and there he not only had in Linaere a better teacher of Greek than he could have found in Paris, but in his intercourse with Colet, a man of nobler stamp than himself, he received an impetus, which if it did not actually give a new bent to his studies, at least lifted his life to a higher plane of endeavour. Through the influence of Colet, his contempt for the schoolmen was intensified, and his thoughts set on the consecration of his studies to a more rational conception of religious truth. During this visit, also, began his famous friendship with Sir Thomas More, through whom on the present occasion he was introduced to Prince Henry (afterwards Henry VIII.), then only a boy of nine.

In 1500 Erasmus was again in France, and for the next six years he made his abode mainly in Paris, with occasional visits of longer or shorter duration to Orleans, and in the Low Countries. To these years belong his *Adagia* (afterwards published in greatly enlarged form in 1515), a collection of Greek and Latin proverbs, with running commentaries, and his *Enchiridion Militis Christiani* (The Christian Soldier's Dagger). A second short visit to England in 1506 cemented still more closely his friendship with More, and gained him a valuable friend in Warham, Archbishop of Canterbury and Lord Chancellor of England. During the same year he carried out a journey to Italy, which for long had been his passionate desire. At Turin he received the degree of Doctor of Divinity; at Bologna he witnessed the military triumph of the bellicose Pope Julius II.—a spectacle which Erasmus always spoke of as a disgrace to Christian Europe; and at Venice he made the acquaintance of the famous printer Aldus Manutius. During his sojourn in Italy he acted for some time as tutor to Alexander, Archbishop of St Andrews, natural son of James IV. of Scotland, who afterwards fell with his father at Flodden. His visit closed with a short stay in Rome, where he was received in a manner that proves the great reputation he had already won in letters. Altogether, as was to be expected from the different temper and aims of the two men, Erasmus carried away from Italy a far more friendly impression than Luther after his memorable visit about the same date. The accession of Henry VIII., of whom great things were expected as a patron of learning, and the special invitation of Lord Mountjoy, induced Erasmus once more to make his home in England. On his journey from Italy to that country he conceived the plan of his *Encomium Moriae* (Praise of Folly), which on his arrival he threw upon paper in the course of a week. In this satire, written in the full maturity of his powers, we have Erasmus in his happiest and most distinctive vein, as the man of letters and the general critic of men and things. While its general tone is that of playful banter, it is yet inspired by the most serious purpose, as specially appears in its biting sarcasm at the

expense of kings and churchmen. Seven editions of this work were issued within a few months.

During this his third and longest visit to England, Erasmus resided chiefly in Cambridge, where he acted as Margaret professor of Divinity, and professor of Greek. After 1514 Erasmus's changes of abode for the next few years are so frequent that it becomes puzzling to follow him. In 1514 he was in Basel, back in England the same year, again in Basel in 1515, and once more in England—the last of his visits to that country. From 1517 to 1521 he lived at Louvain, taking a keen interest in the progress of the new studies at the famous university of that place. Meanwhile, his literary labours were unceasing. In 1519 appeared the first edition (afterwards greatly enlarged) of his *Colloquia*, the most famous of all his works, and usually regarded as his masterpiece. It consists of a series of familiar dialogues on the everyday topics of the time—social, religious, and political; and the audacity and incisiveness with which it handles the abuses of the church in large measure prepared men's minds for the work of Luther. In 1516 his edition of the New Testament, virtually the first of the Greek text, was published at Basel; and in 1519 his edition of St Jerome in nine folio volumes. In both of these works the dominant aim of Erasmus was to introduce a more rational conception of Christian doctrine, and to emancipate men's minds from the frivolous and pedantic methods of the scholastic theologians. By such labours, as by his *Adagia* and *Encomium Moriae*, Erasmus had shown the need for a general reform in the church. When the Lutheran revolution came, therefore, Erasmus found himself in the most embarrassing position. The upholders of the old order fell upon him as the author of all the new troubles, and the followers of Luther, on the other hand, bitterly assailed him for what they deemed his cowardice and inconsistency in refusing to follow up his opinions to their legitimate conclusions.

From the date of Luther's final breach with Rome, the life of Erasmus was one long controversy, which seriously marred the honour and happiness of his declining years. In 1521 he left Louvain, where the champions of the old faith had made his stay unendurable, and took up his abode at Basel. In this city, with the exception of a sojourn in Friburg from 1529 to 1535, Erasmus spent the rest of his life. To Basel he had always been attracted as the home of the great printer Froben, as well as by the excellence of its climate, and he now found it the quietest spot in the general din of religious strife. To the very last his labours were incessant and almost incredible. In addition to the toil of editing a long succession of classical and patristic writers, he was engaged in controversies which would have incapacitated most men for peaceful study. The most important of these controversies were those with Ulrich von Hutten, with Luther, and with the Sorbonne. In accordance with his fiery character, Hutten judged Erasmus with the greatest severity for not taking his place by the side of Luther. With the great Reformer himself, Erasmus, after long hesitation, crossed swords in his *De Libero Arbitrio* (1523), in which he assailed one of the fundamental positions of the Lutheran theology—that all human action is determined by divine necessity. Attacked by men like Hutten on the one side, he was as fiercely assailed on the other by the Sorbonne, the great surviving stronghold of obscurantism alike in theology and secular studies. By his *Ciceroniana*, a satire on the pedantic imitation of Cicero, Erasmus raised against himself a new set of adversaries—those humanists, namely, who set style above matter. Yet in spite of all these contro-

versies, Erasmus during his last years enjoyed fame and consideration beyond that of any man of letters before or since. Letters and presents came to him from all the crowned heads of Europe; and churchmen in the highest position deemed it an honour to be among his correspondents.

Erasmus's health had never been robust even in youth, and from a comparatively early age he had been afflicted with the stone. As he advanced in life, his sufferings grew upon him, and it was only by the most careful ordering of diet, and by his overpowering instinct for study, that he accomplished the work he did. From 1534, a disease resembling gout in its symptoms subjected him at times to excruciating pain. On 12th July 1536, after nearly a month's attack of dysentery, he died, retaining to the last his gay and genial humour.

Erasmus stands as the supreme type of cultivated common sense applied to human affairs. In his latter years he fell upon a time when other qualities were needed in the best interests of humanity; but such as he was, few men have done more to advance truth, and to prepare men's minds for its acceptance. No man of letters has ever attained to anything approaching the influence wielded by Erasmus during his own century. Yet Erasmus was no creative genius, and he produced no single work which has a place in the first rank of the world's masterpieces. He owed his position to the wonderful range of his activity, to his astonishing productiveness, to the breadth and sanity of his views, and to the delightful qualities of wit, humour, and unflinching vivacity which distinguish all his work. He has himself indicated his services to Europe with exactness and precision. He rescued theology from the pedantries of the schoolmen, and referred it to its original sources; he did more than any other single person to advance the cause of the new studies of the Revival of Learning; he exposed the abuses of the church, and he protested in the interests of the people against the thoughtless tyranny of their rulers. His attitude towards the Lutheran revolution has exposed him to the obloquy of Protestants and Catholics alike. By both he has been accused of cowardice and insincerity, because he insisted in maintaining his neutral position. But this is merely to say that Erasmus had the defects of his qualities. Constitutionally, he was averse to all extremes, as he distinctly showed in his antagonism to the excesses of humanism in its neo-pagan developments, not less than to what he considered the excesses of the German Reformation. If he had not the energy to head a revolution, he had at least in eminent degree the courage of the scholar, as the long catalogue of his works, produced in chronic weakness of health, amply proves. As to his personal qualities, it should be sufficient to say that he enjoyed the friendship and esteem of men of so different, yet each in his own way of so high a type, as Bishop Fisher, Colet, and More. His personal appearance corresponded to his mental and moral qualities. He was slightly under the middle height, but of graceful figure; his features were delicate and mobile; and he spoke in tones low but beautifully clear and distinct.

An edition of his works was published at Basel in 9 vols. in 1540; the standard edition is that of Le Clerc (Lyons, 10 vols 1703-6). See *Lives of Erasmus* by Knight (1726), Jortin (1748), Burigny (1752), Durand de Laur (1874), Drummond (1873), and Feugère (Paris, 1874). For studies of Erasmus, see Nisard, *Études sur la Renaissance* (1855); Milman, *Essays* (1870); Seebohm, *Oxford Reformers* (2d ed. 1869).

**Erastus**, THOMAS (properly *Liebler* or *Lieber*), was born in 1524 at Baden in Switzerland, according to other accounts at Auggen, near Mühlheim

in south-west Germany. He studied theology at Basel (where he Grecised his name), and philosophy and medicine at Bologna and Padua. After nine years in Italy, he was appointed physician to the counts of Henneberg; then (from 1558) professor of medicine at Heidelberg, and court-physician to the Elector Palatine. He removed from Heidelberg to fill the chair of Medicine at Basel in 1580, and died there, January 1, 1583. Shortly before his death he had been appointed professor of Ethics. Erastus was a skilful physician and a man of upright character, an equally vigorous writer against 'the new medicine of Philip Paracelsus' (1572) and in favour of the burning of witches (1577 *et seq.*). In theology he was a follower of Zwingli, and represented his view of the Lord's Supper at the conferences at Heidelberg in 1560 and Maulbronn in 1564. The fame of Erastus now rests on his strenuous opposition to Calvinist discipline and Presbyterian order. For ten years (from 1560) he resisted successfully the Calvinist party under Caspar Olevian at Heidelberg; but in 1570 Presbyterianism was introduced by the Elector Frederick III. Erastus was excommunicated on a false suspicion of heresy, founded on a correspondence with Unitarians of Transylvania, but was restored in 1575. He had carried on a private exchange of views on the subject of church discipline with his friend Beza, and after his death his widow's second husband, Castelvetro, published at London (1589), with the concurrence of Archbishop Whitgift and with a fictitious imprint, a treatise on excommunication entitled *Explicatio gravissimæ questionis utrum Excommunicatio . . . mandato nitatur divino, an erogata sit ab hominibus*. This was answered by Beza in his *De verâ Excommunicatione et Christiano Presbyterio* (1590). A translation of Erastus's treatise was published with a preface by Dr Robert Lee (Edin. 1844). Erastus maintained that no member of the church should be excluded from her communion as a punishment for sin. Punishment is 'the special duty and office' of the civil magistrate. He was familiar with the system of Zurich, where the Christian magistrate administered ecclesiastical discipline in the name of the Christian community, and he dreaded that Presbyterianism, unchecked, might exercise a tyranny over men's consciences as absolute as that of the Spanish Inquisition.

In England, the name of Erastians was applied to the party that arose in the 17th century, denying the right of autonomy to the church—a right neither maintained nor denied by Erastus. The Erastian controversy broke out at the time of the Westminster Assembly. The leading Erastians in that assembly were Lightfoot and Coleman, who were supported by Selden and Whitelocke in the House of Commons. Since the time of the Reformation the controversy has been confined chiefly to the church in Scotland.

See on the one side, Gillespie, *Aaron's Rod Blossoming* (1646), Sam. Rutherford, *Divine Right of Church Government* (1646), and Cunningham's *Historical Theology*, vol. ii. chap. xxvii. (1863); and on the other, Selden, *De Synædriis* (1650-53), and Du Moulin, *Of the Right of Churches* (1658).

**Erasure**, or **RAZURE**, as it is more commonly called in England, from the Latin *rado*, 'I scrape or shave,' is the scraping or shaving of a deed or other formal writing. In England, except in the case of a will, the presumption, in the absence of rebutting evidence, is that the erasure was made at or before execution. If an alteration or erasure has been made in any instrument subsequent to its execution, that fact ought to be mentioned (in the abstract, or epitome of the evidences of ownership), together with the circumstances under which

it is done. A fraudulent alteration, if made by the person himself taking under it, would vitiate his interest altogether. It was formerly considered that an alteration, erasure, or Interlineation (q.v.) would void the whole instrument, even in those cases where it was made by a stranger; but the law is now otherwise, as it is clearly settled that no alteration made by a stranger will prevent the contents of an instrument from retaining its original effect and operation, where it can be plainly shown what that effect and operation actually was. To accomplish this, the mutilated instrument may be given in evidence as far as its contents appear; and evidence will be admitted to show what portions have been altered or erased, and also the words contained in such altered or erased parts; but if, for want of such evidence, or any deficiency or uncertainty arising out of it, the original contents of the instrument cannot be ascertained, then the old rule would become applicable, or, more correctly speaking, the mutilated instrument would become void for uncertainty. If a will contains any alterations or erasures, the attention of the witnesses ought to be directed to the particular parts in which such alterations occur, and they ought to place their initials in the margin opposite, before the will is executed, and to notice this having been done by a memorandum, added to the attestation clause at the end of the will. For the English law on this subject, see Taylor, *Laws of Evidence* (8th ed. 1835).

In Scotland, the rule as to erasure is somewhat stricter than in England—the legal inference being that such alterations were made after execution. As to necessary or *bona fide* alterations which may be desired by the parties, corrections of clerical errors, and the like, after the deed is written out, but before signature, the rule in Scotland is that the deed must show that they have been advisedly adopted by the party; and this will be effected by mentioning them in the body of the writing. Thus, if some words are erased and others superinduced, you mention that the superinduced words were written on an erasure; if words are simply deleted, that fact is noticed; if words are added, it ought to be on the margin, and such additions signed by the party, with his Christian name on one side, and his surname on the other; and such marginal addition must be noticed in the body of the writ, so as to specify the page on which it occurs, the writer of it, and that it is subscribed by the attesting witnesses. See Menzies's *Lectures on Conveyancing*. The Roman rule was that the alterations should be made by the party himself, and a formal clause was introduced into their deeds to this effect, 'Lituras, inductiones, superinductiones, ipse feci.' As a general rule, alterations with the pen are in all cases to be preferred to erasure; and suspicion will be most effectually removed by not obliterating the words altered so completely as to conceal the nature of the correction. 'The worst kind of deletion,' says Lord Stair, 'is when the words deleted cannot be read (but if they are scored that they can be read, it will appear whether they be *de substantialibus*), for if they cannot be read, they will be esteemed to be such, unless the contrary appear by what precedes and follows, or that there be a marginal note, bearing the deletion, from such a word to such a word, to be of consent.' The law of the United States follows that of England in this matter.

**ERATOSTHENES** OF CYRENE, born 276 B.C., was an eminent mathematician, astronomer, and geographer. Among his teachers were Lysanias the grammarian and Callimachus the poet. By Ptolemy Energetes he was called to Alexandria to superintend his great library. Here he died of

voluntary starvation, at the age of eighty, having become blind, and wearied of life. Eratosthenes measured the obliquity of the ecliptic with an accuracy wonderful for his time, drew up a catalogue of the fixed stars, amounting to 675, which is now lost, and made an attempt to measure the magnitude of the earth in the method used at the present day. He found the circumference of the earth to be 252,000 stadia, which, according to Pliny, is 31,500 Roman miles. His most important work was a systematic treatise on geography, which was used by Strabo. He wrote also on moral philosophy, history, and grammar. Such fragments of his writings as are still extant have been collected by Bernhardt in his *Eratosthenica* (Berlin, 1822). See also Berger, *Die geographischen Fragmente des Eratosthenes* (Leip. 1880).

**Erbium** (sym. Er, eq. 170.5) is a rare metal, the compounds of which are present in the mineral *gadolinite*, found at Ytterby in Sweden. It is also believed to be present in the sun's vapour. It is found along with compounds of yttrium and, it is alleged, of terbium, also rare metals, the existence of one of which, terbium, is still questioned. It is chiefly of interest because the compounds of the three metals mentioned resemble each other so closely, and have such similar properties, that the processes of separation and purification are difficult and tedious in the extreme, a single research with the object of obtaining absolutely pure salts requiring years of patient work.

**Ercildoune.** See EARLSTON.

**Ercilla y Zúñiga**, ALONSO, a Spanish poet, was born at Madrid, August 7, 1533. He became page to the Infante Don Philip, son of Charles V., and accompanied him on his early travels, and in 1554 to England, on the occasion of Philip's marriage to Queen Mary. Shortly after he joined the expedition against the Araucanians on the coast of Chili. The arduous difficulties that had to be overcome, and the heroism of the natives, suggested to Ercilla the idea of making it the subject of an epic poem. He began his poem on the spot, about the year 1558, occasionally committing his verses, in the absence of paper, to pieces of leather. An unfounded suspicion of his having plotted an insurrection involved him in a painful trial, and he had actually ascended the scaffold before his innocence was proved. Deeply wounded, the brave poet-soldier turned to Spain, but Philip treating him with great coldness and neglect, he made a tour through France, Italy, Germany, Bohemia, and Hungary. For some time he held the office of chamberlain to the Emperor Rudolf II., but in 1580 returned to Madrid, where he struggled with poverty till his death, about 1595. Cervantes in *Don Quixote* compares the *Araucana* with the best Italian epics, and it has undoubtedly not a little of the epic style and spirit. The first part is the freshest in character, and was published in 1569; the second part followed in 1573, the third in 1597. The most elegant reprint is that published at Madrid in 1776; the most accurate, that issued there in 1828. There is a French translation by Nicolas (1870). See Royer's *Étude* (Dijon, 1880).

**Erckmann-Chatrian**, the compound name of two French romancists, Lorrainers both, whose stories of Alsatian peasant life are known the whole world over. Émile Erckmann, born 20th May 1822, at Phalsbourg, studied law in Paris from 1842 to 1858; whilst Alexandre Chatrian, born 2d December 1826, in the village of Soldatenhof, from glass-blowing took to teaching in Phalsbourg, and afterwards got a railway clerkship. Their literary partnership dates from 1848; but for ten or eleven

years they had little success beyond getting some of their stories printed in various newspapers and journals. It was not till 1859 that *L'Illustre Docteur Mathéus* (1859) gave a certain éclat to the collective name of Erckmann-Chatrian. *Le Fou Yégo* (1862) is one of a series of novels which give graphic pictures of the invasion of 1813-14, to which series also belong *Histoire d'un Conscrié de 1813* (1864) and *Waterloo* (1865). *Le Joueur de Clarinette* (1863), a simple story of a village musician; *Les Amoureux de Catherine*, another tale of village life in the same volume; *L'Ami Fritz* (1864); *Madame Thérèse, ou les Volontaires de '92* (1863); *Le Blocus* (1867; Eng. trans. *Blockade of Phalsbourg*, 1870); *Histoire d'un Paysan* (1868); and *Contes Populaires*, most of which have been translated into English, count amongst the best they have written. Three plays by them have also achieved success—*Le Juif Polonais* (1869; well known in English as *The Bells*), the dramatic version of *L'Ami Fritz* (1876), and *Les Rantau* (1882). After the annexation of Alsace-Lorraine to Germany, a strong anti-German feeling was manifested in several of their books—the best of these *L'Histoire d'un Plébiscite* (1872). They had quarrelled latterly, when Chatrian died 4th September 1890. Edmond About thus described their partnership: 'The two friends see one another very rarely. When they do meet, they elaborate together the scheme of a work. Then Erckmann writes it, Chatrian corrects it, and sometimes puts it in the fire.'

**Erckmann**, JOHANN EDUARD, German philosopher, was born in 1805 at Walmir in Livonia (Russia), studied at Dorpat and Berlin, coming, at this last university, under the influence of Hegel, and became professor of Philosophy at Halle (extraordinary 1836) in 1839. His principal work is a *Grundriss der Geschichte der Philosophie* (3d ed. 1877), besides which he also wrote a work on Logic and Metaphysics, two books on Psychology, two collections of essays (one entitled *Ernte Spiele*), and works on *Nature and Creation*, *Body and Soul*, *Belief and Science*, and *The State*.

**Erebus**, the name of one of the sons of Chaos, signifies darkness, and is used specially to denote the dark and gloomy cavern beneath the earth, through which the shades pass in going to Hades.

**Erebus**, MOUNT, an active volcano on Victoria Land, in 78° 10' S. lat., rising 12,367 feet above the sea. It was discovered in 1841 by Ross, who named it after one of his vessels, and whose further progress south was barred by a wall of ice. See ANTARCTIC OCEAN.

**Erechtheus**, or ERICHTHONIUS, an Attic hero, is said to have been the son of Hephaestus and Athia, daughter of Cranaus, the son-in-law and successor of Cecrops. He was brought up by Athena, who placed him in a chest, which was entrusted to Agramos, Pandrosos, and Herse, the daughters of Cecrops, with the strict charge that it was not to be opened. Unable to restrain their curiosity, they opened the chest, and discovering a child entwined with serpents, were seized with madness, and threw themselves down the most precipitous part of the Acropolis. Afterwards Erechtheus was the chief means of establishing the worship of Athena in Attica. He instituted the Panathenaea, and a temple, the Erechtheum, was erected in his own honour. This original Erechtheum was burned by the Persians, but a new and magnificent Ionic temple was raised on the same site (see ATHENS). Mr Swinburne in 1876 published his tragedy of *Erechtheus*.

**Eretria**, an ancient Ionic trading and colonising town on the SW. coast of Euboea, which was destroyed by the Persians in 490 B.C., and, although rebuilt by the Athenians, never after-

wards regained its former prosperity and importance. The modern town of Nea Eretria is a small, unwholesome place, surrounded by swamps.

**Erfurt**, a city of Prussian Saxony, anciently capital of Thuringia, stands in a highly cultivated plain, on the Gera, 13 miles W. of Weimar by rail. Till 1873 it was strongly fortified. Its two citadels, the Petersberg and the Cyriaksburg, were formerly monasteries. Erfurt has several churches, chiefly Gothic, the cathedral and the church of St Severus being the finest. The cathedral, one of the most venerable Gothic buildings in Germany, possesses, besides a very rich portal, sculptures and bronze castings dating from the 13th to the 16th century, especially a Coronation of the Virgin, by Peter Vischer (1521). In the northern tower is the bell called *Maria Gloriosa*, cast in 1497, and weighing 13½ tons. The Regler Church contains an altarpiece by Wohlgemuth. The monastery of St Augustine, famous as the residence of Luther, whose cell was destroyed by fire in 1872, was converted in the year 1819 into an asylum for deserted children. From 1378 to 1816 Erfurt was the seat of a university, of which the academy of sciences and the library (60,000 volumes and 1000 MSS.) alone remain. The growing of flowers and vegetables, and an extensive trade in flower-seeds, are carried on. The principal manufactures are woollen, silk, cotton, and linen goods, lamps, machines, shoes, beer, malt, &c. Pop. (1871) 43,616; (1880) 53,254; (1885) 58,385.

Erfurt, originally called Erpesford or Erpesfurt, was made a bishopric in 741, and in 805 the capital of the Sorbs by Charlemagne. In the 15th century its woollen and linen manufactures raised it to the position of one of the foremost cities of Germany. All through, the town has had a stormy history, being either the bone of contention between the electors of Mainz and of Saxony, or the object of attack by foreign invaders. Since 1803 (except the period from 1806 to 1814) it has belonged to Prussia. At the Congress of Erfurt (September-October 1808) Napoleon met the Emperor of Russia and several of the minor sovereign princes of Germany.

**Ergasteria**, a mining-town in the Greek nomarchy of Attica and Boeotia, near Cape Colonna, with ancient lead and silver works, reopened in 1864. Pop. 6300.

**Ergot**, a diseased condition of the ovary of grasses and sedges, due to the presence of species of *Claviceps*, a *Pyrenomyces* fungus (see FUNGI), of which the filamentous mycelium of the mould ramifies through the tissue of the flower, causing the outpouring of sugary sap, and bearing a multitude of spores, the ovary meantime becoming deformed and enlarged. In this state the mould was formerly described as a distinct species. This now withers on the surface, but the deeper mycelium within the ovary becomes denser and harder, forming the so-called sclerotium, and lies dormant until the grain is sown in early spring, when it bears globular heads which contain depressions or perithecia, containing

Ergot of Rye.

the ascospores, which again recommence the cycle. The medicinal 'ergot of rye' is that formed by *Claviceps purpurea*. Producing rapid contraction of the uterus, it is often employed in midwifery; but its use in unskilled or unscrupulous hands is attended by the most serious risks. It has also been used in dysentery, epilepsy, whooping-cough, and as a styptic. The continued eating of bread made of ergotised rye produces a specific disease called *Ergotism*. This is a terrible form of poisoning, in which not only convulsions appear, but often also gangrene of the extremities, resulting in mutilation or death, even recovery from less serious doses being slow and difficult. Many dreadful epidemics in rye-consuming countries (as in Lorraine and Burgundy in 1816), the causes of which were not understood, are now supposed to have been due to ergotism. See also RAPHAIA.

**ERIC**, the name of several Danish and Swedish kings.—**ERIC VII.**, king of Denmark, born in 1382, the son of Duke Wratislav of Pomerania, was selected as her successor by Queen Margaret of Denmark, and in 1412 mounted the throne of Denmark, Norway, and Sweden, united according to the treaty of Calmar. Cruel and cowardly in his character, he lost Sweden in 1437 through a revolt of the peasants of Dalecarlia, and in 1439 was deposed also in Denmark. He died in Rügen-wald in 1459.—**ERIC VIII.**, the Saint, became king of Sweden in 1155, did much to extend Christianity in his dominions, and to improve the laws, and fell in battle with the Danes in 1160.—**ERIC XIV.**, the last of the name who reigned in Sweden, succeeded in 1560 to the throne of his father, the great Gustavus Vasa, and at once began to exhibit the folly that disgraced his reign. His slight matrimonial schemes reached even Elizabeth of England and Mary of Scotland, until at length (1567) his roving fancy found rest in the love of a Swedish peasant-girl, who acquired an influence over him which was ascribed by the superstitious to witchcraft, since she alone was able to control him in the violent paroxysms of blind fury to which he was subject. His capricious cruelties and the disastrous wars that followed on his follies at length alienated the minds of his subjects, who threw off their allegiance in 1568, and solemnly elected his brother John to the throne. Nine years later the unhappy Eric ended his miserable life half voluntarily by a cup of poison. This crazy madman had a genuine love of letters, and solaced his captivity with music and the composition of psalms. His story has been worked into dramatic form by Swedish poets; in German by Kruse in his tragedy, *König Erich* (1871).

**ERICA**, or **HEATHS**, a large, widely distributed order of corollifloral dicotyledons, chiefly small shrubs, frequently evergreen and social in growth, covering large areas, especially in mountainous regions and on tablelands. See **HEATH**, **RHODODENDRON**, **AZALEA**, **ANDROMEDA**, **ARBUTUS**, **CRANBERRY**, **KALMIA**, &c.

**ERICH**, **LOCH**, a lonely lake between Perth and Inverness shires, 1 mile from Dalwhinnie station, and 60 miles NW. of Perth. Lying 1153 feet above sea-level, it stretches 14½ miles south-westward, varies in width between ¼ and 1½ mile, is overhung by Ben Alder (3757 feet), abounds in salmo-ferox and trout, and sends off a stream 6 miles to Loch Rannoch.

**ERICSSON**, **JOHN**, a distinguished engineer, was born at Langbanshyttan, in the Swedish province of Vermland, in 1803. After serving for some time as an officer of engineers in the Swedish army, he removed in 1826 to England, and continued to occupy himself with improvements chiefly on steam machinery and its applications. In 1829, for the

Liverpool and Manchester railway race, he built within six weeks (so it is said) the *Novelty*, a steam-engine which, had not the fan broken down at the last moment, might have proved a formidable competitor to Stephenson's *Rocket*. In 1836 he took out a patent for the Screw-propeller (q.v.). In 1839 he went to the United States, where he furnished designs for the warship *Princeton*, the first steamer that had her engines and boilers entirely below the water-line, and brought out his improved caloric engine (see **AIR-ENGINE**) and numerous other inventions. In 1861, during the civil war, he designed and finished in one hundred days the ironclad *Monitor* (see **NAVY**, Vol. VII. p. 418), and in 1862 built a number of similar vessels for the American navy. The *De-stroyer*, a vessel with under-water guns, from which projectiles enclosing 300 lb. of gun-cotton were to be fired into an enemy below her armour-plating, was tried in 1881, but failed to satisfy the requirements of the navy board. In 1883 he erected a 'sun motor' in New York: his earlier experiments for developing power from the direct rays of the sun are described in his magnificent volume, *Contributions to the Centennial Exhibition* (1876). He died in New York, 8th March 1889. By his own wish he was buried in the place of his birth, a United States man-of-war conveying his body in 1890 to Langbanshyttan; and it was decided to erect his statue in Stockholm. His inventions cover nearly the whole field of mechanical engineering, and have revolutionised both the navigation and the navies of the world. His great services to science were recognised by the governments of the United States, Sweden, Denmark, Spain, and Austria, as well as by many learned societies in America and Europe. See his *Life* by W. C. Church (1891).

**Eridanus**. See **PO**.

**ERIC**, one of the five great lakes which empty themselves by the St Lawrence, separates the province of Ontario, in Canada, on its left, from Michigan, Ohio, Pennsylvania, and New York on its right. It is the most southern of the five, receiving at its western extremity the waters of Lakes Superior, Michigan, and Huron by the river Detroit, and discharging them at its north-east by the Niagara into Lake Ontario. With a length of 240 miles, Eric has a breadth varying from 30 to nearly 60 miles, with an area of 9960 sq. m. It is 8½ feet below the Huron, and 320 and 573 respectively above the Ontario and the Atlantic. The shores are for the most part low and of a clayey nature. At its south-western extremity are several wooded and partly cultivated islands, the largest of which is about 14 miles in circumference. It is by far the shallowest of the five great lakes. Its mean depth is 70 feet, its maximum 210 feet; and from this comparative shallowness and the consequent liability to a heavy ground-swell, as well as on account of the small number of good harbours, the navigation is peculiarly difficult and dangerous. The chief harbours on the United States shore, besides the natural harbour of Erie itself or Presque Isle, are those of Buffalo, Dunkirk, Cleveland, Sandusky, and Toledo; and on the north or Canadian shore, Ports Dover, Burwell, Colborne, and Stanley. Lake Erie receives no rivers of any consequence, except the Detroit and Maumee. Its commercial importance, however, has been largely increased by art. It is connected by one canal with the Hudson, and by more than one with the Ohio (see **CANAL**); while, on the British side, it communicates with the Ontario by means of an important work, the ship-channel of the Welland Canal. Its navigation generally closes in the beginning of December, and the lake remains more or less frozen till March or April.

The commercial importance of this lake has been greatly enhanced within recent years by the establishment of numerous lines of railway connecting its ports with the interior. The amount of traffic on the lake and on these railways is enormous. Lake Erie was the scene of a naval engagement between the British and Americans, September 10, 1813, in which the latter were victorious.

**Erie**, the capital of Erie county, Pennsylvania, on Lake Erie, 83 miles SW. of Buffalo, and 95 NE. of Cleveland, is a port of entry, an important centre of trade, and connected by rail with New York, Philadelphia, Pittsburg, and other cities. Its harbour, one of the largest and best on the lake, is formed by an island of 4 miles in length, which, under the appellation of Presque Isle (Fr., 'peninsula'), still preserves the memory of its having been once connected with the mainland. The belt of water thus sheltered is known as Presque Isle Bay, and forms a natural harbour for the city; it is now protected by a breakwater, is 3 to 4 miles long and 1 mile wide, and varies in depth from 9 to 23 feet. The Erie Extension Canal, connecting the city with the Ohio River, was abandoned in 1871; it had never paid half the interest of its cost, and was operated for some thirty-eight years at a loss. The town's important industrial works include oil-refineries, tanneries, iron-foundries, paper, flouring, and planing mills, factories for railroad cars, engines and boilers, &c. It is a Roman Catholic bishop's see. A natural-gas well was opened here in 1889. Pop. (1870) 19,646; (1880) 27,737.

**Erigena**, JOHANNES SCOTUS, a famous philosopher of the 9th century, according to one account was born at 'Ergone,' in Herefordshire, to another at Ayr, but was more probably a Scot of Ireland, and born there between 800 and 815. His residence at the court of Charles the Bald, in France, where he was from 843 the head of the 'court school' (*schola palatina*), is the only part of his history that is certainly known. He came (851) to the help of Hincmar in the Predestination controversy with the doctrine, hitherto unknown in the West, that evil is simply that which has no existence, and that therefore damnation is not a positive punishment by God, but only consists in the consciousness of having failed to fulfil the divine purpose. The Council of Valence condemned this *pultes Scotorum* ('Scots porridge') as 'an invention of the devil.' The tradition is that, after the death of Charles the Bald (877), Erigena was forced to leave France under the suspicion of heresy, was called to England by Alfred the Great, and died about 880, as abbot of Malmesbury, a violent death at the hands of his scholars. But this tradition seems unsupported, and good authorities have convinced themselves that he never left France, but died there about 877. Erigena translated only too literally, into Latin (860), the writings of the pseudo-Dionysius the Areopagite, and afterwards the Greek scholia of Maximus to the writings of Gregory Nazianzen. His chief work, *De Divisione Naturæ*, lib. v. (854), was condemned by a provincial council at Sens, and by Pope Honorius III. (1225), who described the book as 'swarming with worms of heretical perversity.' It was published by Gale (Oxford, 1681), and by Schlüter (Münster, 1638), and was placed on the *Index librorum prohibitorum* by Gregory XIII. in 1685. (There is a German translation by Noack, 1872-76.) In this work Erigena develops a speculative system on the basis of the gnosis of Origen, the theosophy of the Areopagite, and the dialectic of Maximus Confessor. His aim was to reconcile the fundamental truths of Christianity with human reason, but his system is simply Pantheism, in which God and the

world are merged in the higher unity of 'Nature.' Nature—to Erigena the sum of all being and not-being (the necessary complement of being)—has a fourfold form of existence: (1) *Natura creans non creata*—i.e. God, as the uncreated Creator of all things; (2) *Natura creata creans*—i.e. the Word from God, by whom all things are made (the Son); (3) *Natura creata non creans*—i.e. the world, creation, or nature in the narrower sense; (4) *Natura non creans et non creata*—i.e. God, as the final goal of all creation, to whom everything created returns in a universal Apocatastasis (q.v.). Recent writers have shown that Erigena is to be regarded not as an independent thinker, but as a skilful reproducer of Greek speculations.

The complete edition of the works of Erigena, edited by H. T. Floss, forms vol. cxxii. (Paris, 1853) of the *Patrologia* of Migne. His Life has been written by Staudenmaier (1834) and Hermens (1868). See the monographs by St René Taillandier (1843), Christlieb (1860), Huber (1861), Hoffmann (1876), and Buchwald (1884); and the sketch in F. D. Maurice's *Medieval Philosophy* (1856).

**Erigeron**, a genus of composite weeds, allied to Aster. The British *E. acer*, sometimes called Fleabane, has been used as a source of potash, and was formerly in medicinal repute. *E. canadense* has become a common weed in Europe.

**Erim**. See IRELAND.

**Erinna**, a Greek poetess, the intimate friend of Sappho, born at Rhodes, or on the little island of Telos, to the west of Rhodes. The hypothesis of a second poetess of the same name, in the 4th century B.C., which is based on a statement of Eusebius, is generally rejected. Though she died at the early age of nineteen, Erinna acquired such celebrity by her epics, that her verses were compared with those of Homer. Of her principal poem only four lines are extant; and, of the three epigrams preserved in Schneider's *Delectus Poesis Græcæ Elegiacæ* (Göttingen, 1839), two at least are not genuine.

**Erinyes**. See EUMENIDES.

**Eriobotrya**. See LOQUAT.

**Eriocaulaceæ**, a small order of monocotyledons, allied to Restiaceæ, of grassy or rushy aspect, of marsh or aquatic habit, and unimportant properties. The 300 species are chiefly tropical; the North American *Eriocaulon septangulare* (Pipewort), however, occurs in muddy lake bottoms in West Ireland and the Hebrides.

**Eriodendron**, a genus of Sterculiaceæ, allied to Bombax, East and West Indian trees with woolly seed; hence often called Wool-trees. The wool is sometimes used for stuffing pillows, &c., and the seeds yield oil, or are sometimes eaten.

**Eris**, in Greek mythology, the sister of Ares, and personification of strife.

**Erith**, a town of Kent, on the right bank of the Thames, 15½ miles by rail E. of Charing Cross. A summer-resort for Londoners, a steamboat-station, and the headquarters of several yacht clubs, it has a number of fine villas, and a much-restored church, rich in brasses; whilst in the Erith and Plumstead Marshes are large powder magazines, one of which in October 1864 was the scene of a great explosion. At Erith the *Grace de Dieu* was built in 1515. Pop. of parish (1851) 3231; (1881) 9812. See C. J. Smith's *History of Erith* (1873).

**Erivan** (Persian *Revân*), the fortified capital of the government of the same name in Transcaucasia, is situated on the elevated plain to the north of Ararat, on the river Sanga, 3432 feet above the level of the sea. It has one Russian and six Armenian churches, and five mosques, besides a citadel and a large bazaar. Close by resides the head of the Armenian Church (see ARMENIA, Vol. I.

p. 425). The town dates probably from the 7th century A.D.; in later years it was held alternately by Persians and Turks. Pop. (1880) 12,449. In 1827 it was stormed by the Russian general, Paskewich, who received the surname of Erivanski; and by the treaty of peace concluded at Turkmanjai, 22d February 1828, both town and province were given up by Persia to Russia. The province has an area of 10,165 sq. m., and a pop. (1885) of 667,464, nearly all Armenians and Tatars, with a small percentage of Kurds, and barely 5000 Russians.

**Erlangen**, a town of Bavaria, on the Regnitz, 12 miles N. of Nuremberg. As old as the 10th century, it owes its prosperity to the settlement here of French Huguenots after the revocation of the Edict of Nantes (1685), and to its university (1743), which is celebrated as a school of Protestant theology, and attended by from 600 to 900 students. A statue of its founder, the Margrave Frederick of Brandenburg-Bairreuth, was erected in the marketplace in 1843. Brewing is the staple industry; and besides its extensive stocking and glove manufactories, which provide the greater part of Germany with their goods, Erlangen has great mirror and tobacco factories. Burnt in 1449 and 1632, Erlangen came to Bavaria in 1809. Pop. (1875) 13,597; (1885) 13,814, of whom four-fifths are Protestants.

**Erlau** (Hung. *Eger*), a city of Hungary, on the river Erlau, 80 miles N.E. of Pesth by rail. The archiepiscopal cathedral, built since 1837, at a cost of £87,000, is a domed cruciform building, 328 feet long. The lyceum (1761-99) has a valuable library and an observatory; and there is a richly-endowed hospital (1830). Two warm baths are much resorted to. The Erlau wine is the best red wine of Hungary. Pop. (1870) 19,150; (1880) 20,669. Dating from 1010, Erlau suffered much at the hands of the Turks, who held it from 1396 till 1687.

**Erlikönig**, a German mistranslation (meaning 'alder king') of the Danish *Ellerkonge* (i.e. *Elverkonge*, 'king of the elves'). It was first used by Herder instead of the corresponding German word *Elfenkönig*; and Goethe followed Herder in his famous ballad (set to remarkable music by Schubert), in which a human child is carried off by the Elking, and dies in his cold arms. See FAIRIES.

**Ermland**, or **ERMILAND**, one of the eleven districts of the old province of Prussia, extending inland from the Frisches Haff, was created in 1250 one of the four bishoprics of the country of the Teutonic Knights. In 1354 the Bishop of Ermland, who hitherto had been subject to the Archbishop of Riga, was made directly dependent upon the pope, and elevated to the position of a prince of the empire. When, in 1466, West Prussia was transferred to Poland, the Bishop of Ermland became a member of the Polish senate, with sundry privileges. Since 1722 Ermland and its bishop have again been Prussian. The name is still borne by a Prussian district (area, 1640 sq. m.; pop. in 1885, 225,076), with sandy soil, but well wooded, in which a large quantity of flax is grown.

**Ermenonville**, a village in the French department of Oise, 18 miles NNE. of Paris. It was the death-place of Rousseau (q.v.).

**Ermine**, or **STOAT** (*Putorius erminea*), a well-known carnivore in the marten family (*Mustelidae*), belonging to the genus which includes pole-cat, weasel, ferret, mink, &c. The body is long and slender, and the legs are short, as in the more familiar weasel. The length of the body is about 10 inches, to which 3 or 4 inches of tail are added. The colour of the stoat is ruddy brown in summer, yellowish beneath; but in winter, in the more northern parts of its distribution, the ermine

changes its fur into a beautiful white. That this change occurs in direct association with the lowered temperature seems certain, though the physiology of the process is not understood. Observations seem to show that not only is the new growth of hair at the beginning of winter white, but persistent old

Ermine (*Putorius erminea*): Summer and Winter Fur.

hairs may also change. The end of the tail always remains black, and the change is sometimes only partial. The protective value of the white fur in snowy regions is obvious. Like related species, the ermine is a very lithe, restless, brave, and blood-thirsty animal; it moves rapidly, and can both climb and swim well; it is terrestrial in its general habit, and finds a home among rocks and stones, in walls and the like. It sucks the blood of small mammals and birds, and, while valuable in destroying rats and mice, is sometimes a troublesome poacher on the poultry-yard. It breeds at the end of the winter season.

The ermine occurs in Britain, especially in the north, is generally distributed in the northern parts of Europe, Asia, and America, but is common as far south as the Pyrenees and the Italian Alps. The white fur, which has long been used for trimming or lining the robes of dignitaries, is not so much prized as it used to be. The skins are usually imported from Norway, Lapland, Siberia, and the Hudson Bay Territories. The yellow and black tails are inserted to contrast with the white fur. Ermine is the fur of most frequent use in Heraldry (q.v.). See FERRET, MARTEN, POLE-CAT, WEASEL.

**Erne**, a river and lake in the south-west of Ulster province, Ireland. The river rises in Lough Gowna, on the borders of Longford and Cavan counties, and flows 72 miles north-west through Loughs Oughter and Erne into Donegal Bay. Lough Erne, one of the finest lakes in the kingdom, extending for 40 miles through Fermanagh county, consists of two lakes, the Upper and Lower, joined by a network of channels 10 miles long. Both divisions are studded with green hilly lands, and contain abundance of salmon, trout, and other fish.

**Erne** (*Haliaeetus*), one of the 'bare-legged' eagles. The genus includes some seven species, represented apparently in all parts of the world except South America. The Common Erne or White-tailed Sea-eagle (*H. albicilla*) is widely distributed in northern Europe and Asia. It occurs in Britain more commonly than the Golden Eagle (*Aquila chrysaetos*), but, like the latter, with rapidly increasing rarity. The two cannot be readily confused, for the leg-feathers of the erne do not extend to the toes, the bill is longer, and the habit is different. The erne is rather smaller than

the golden eagle, measuring about 3 feet in length. The general colour is brown, but the head may be paler, and the tail (which only extends very slightly beyond the points of the wings) is white above in the adults. The young erne is a grayer bird. In Britain the erne is now most at home in the remote north—e.g. in the Hebridean and Shetland islands.

Common Erne (*Haliaeetus albicilla*).

It there builds by the precipices of the coast, but in North Germany it finds a home in wooded inland regions where water is abundant. The same habit has also been noticed in the British Islands—e.g. at Killaney. While continuing the depredations on birds and mammals characteristic of most eagles, the ernes also find in fish a favourite diet.

Another notable species is the White-headed or Bald Eagle (*H. leucocephalus*), the emblem of the United States. In powers of soaring the emblem may be a happy one, but Franklin regrets that the habits and disposition of the bird are not more praiseworthy. This erne is common in North America, both by the coasts and by inland lakes, and also occurs in northern Europe. The general colour is again brown, but the head and neck of the adults are milky-white, and the same is true of the rounded tail. The size is slightly less than that of the British species. It feeds like other eagles, but is very fond of fish, which it gets for itself by wading, or obtains by theft from other birds. The White-bellied Sea-eagle (*H. leucogaster*), found round the Australian coasts, and from Ceylon to Cochin-China; the beautifully marked *H. vocifer* of Africa and Madagascar; and the Asiatic Erne (*H. pelagicus*), are other important species. See EAGLE.

**Ernest**, the name of several German princes, for whom see HANOVER, SAXONY, SAXE-COBURG, ALTENBURG.

**Ernesti**, JOHANN AUGUST, a celebrated classical and biblical critic, was born at Tennstädt, in Thuringia, 4th August 1707. He studied (from 1726) at Wittenberg and Leipzig, and, devoting himself to classical studies, became rector of the Thomas School at Leipzig in 1734, a post which he held till 1759, along with first a chair of Humanity (from 1742), and then that of Rhetoric (from 1756) in the university. Becoming professor of Theology in 1759, he resigned the chair of Rhetoric in 1770, and died 11th September 1781. He prepared editions of Homer, Callimachus, Polybius, Suetonius, and Tacitus, and of Xenophon's *Memorabilia* and Aristophanes' *Clouds*, and an excellent edition of Cicero (3d ed. 5 vols. 1776-77), to which he added a valu-

able *Clavis Ciceroniana* (6th ed. by Rein, Halle, 1831). Ernesti was the chief founder of a correct exegesis of Scripture by the laws of grammar and history, independent of dogmatic prepossessions. Of his numerous theological writings the most notable is his *Institutio Interpretis Novi Testamenti* (1761; 5th ed. 1809), of which there are English translations by Moses Stuart (2d ed. Andover, 1824) and C. H. Terrot (2 vols. Edin. 1832-33). In his *Anti-Muratorius* (1755) he shows that a fair and thorough investigation of the history of doctrines is the best polemic against Roman Catholicism. His Latin speeches gained for him the name of the 'German Cicero.' They are collected under the title *Opuscula oratoria* (2d ed. 1767), with a supplementary volume (1791).

**Eros**. See CUPID.

**Erosion**, the influence of rivers or of flowing water in hollowing out their channels, and in wearing down and sculpturing the surface of the earth. See COLORADO, DENUDATION, GEOLOGY, MOUNTAINS, RIVERS.

**Erostratus**, or HEROSTRATUS. See EPHEBUS.

**Erotic Poetry** (from the Greek *erōs*, 'love') comprises poetical pieces of which love is the predominating subject.

**Erotomania**. See MANIA.

**Erpenius** (Latinised from Thomas van Erpen), one of the earliest and most eminent of European Orientalists, was born at Gorkum, in Holland, 7th September 1584, studied at Leyden, and at Paris learned Arabic from an Egyptian. In 1613 he became professor of Oriental Languages at Leyden, where he erected an Arabic press in his own house, caused elegant new types to be cut, and not only wrote but printed a great number of important works bearing on his favourite studies. At the time of Erpenius's translation to the university of Leyden, a second Hebrew chair was founded. As oriental interpreter to the government, he read and wrote replies to all official documents coming from the East. Tempting offers of honours and distinction reached him from all parts of Europe; but he was never prevailed upon to leave his native country, where, in the midst of an eminent career, he died of the plague, 13th November 1624. Eastern, and especially Arabic, studies owe much of their development to Erpenius's labours. In spite of his poverty of materials, his famous grammar (*Grammatica Arabica*, Leyden, 1613) enjoyed an undisputed supremacy for two hundred years, till the time of Silvestre de Sacy; and there are many who think his *Rudimenta* (1620) unsurpassed, even at the present day, as a work for beginners. Among his other important works the best known are his *Proverbiorum Arabicorum Centuria Duca* (1614), and his edition and translation of El-Mekki's *Historia Saracenica* (1625).

**Errata**, the list of errors with their corrections placed at the end of a book. From greater carefulness in correcting the sheets of a work in passing through the press, errors in sense or typography are now much more rare than formerly; but few books are yet produced without more or less noticeable typographical errors.

**Erratics**. See BOULDERS, BOULDER-CLAY, GLACIAL PERIOD.

**Error**, in English law, is any mistake in fact, in law, or in the form of process, requiring to be set right by the court before which an action is tried, or by a court of review. If the error was in fact, the case, under the old system, was heard before the court in which the action was originally tried; if the error was in law, proceedings had to be taken before the Court of Exchequer

Chamber (q.v.). Where a party disputed the ruling of the judge, the form was by Bill of Exceptions (q.v.). According to the former practice, it was necessary, in order to obtain a review on the ground of error, that an original writ, called a Writ of Error, should be issued. The writ, if the error was in fact, was styled *coram nobis*, where the case was in the King's Bench, the sovereign being presumed to preside in that court; if in the other courts, the writ was *coram vobis*. Writ of error in civil cases in the High Court is abolished by the Judicature Acts, and so is Bill of Exceptions. Since 1875 all appeals are to the Court of Appeal by way of rehearing, and are brought by notice of motion in a summary way, and no petition or other formal proceeding other than such notice of motion is now necessary. The appellant may by the notice of motion appeal from the whole or part of any judgment, and this does not usually stay proceedings. Nearly all the judgments of the Divisional Courts of the High Court are subject to appeal to the Court of Appeal and thence to the House of Lords. The jurisdiction was transferred to the High Court of Justice in 1875, which used formerly to be vested in the Common Pleas at Lancaster and at Durham, and which used to be by writ of error to the Queen's Bench. Writs of error used formerly also to be brought on judgments of inferior courts. But since the establishment of County Courts and the changes introduced by the Judicature Acts, the analogous proceeding is an appeal by way of a case stated for opinion of the High Court, and sometimes by motion in a summary way. In criminal cases, error does not now lie for formal defects in the indictment; these should be objected to before the jury is sworn, and may then be amended. A writ of error will lie for a defect in substance appearing in the indictment, as in the case of *Bradlaugh v. the Queen*, where an indictment for publishing an obscene book was held defective because it mentioned the book by title only, instead of setting out the passages alleged to be obscene. A prisoner has therefore three opportunities of taking legal objections; he may demur to the indictment, or move in arrest of judgment, or sue out a writ of error. On the facts in a criminal case there is no appeal from the verdict of the jury. In the United States, the procedure of the State Courts follows the analogy of the English common law; in the Federal Courts the term error is also known; for further details reference may be made to the Acts of Congress and of the several state legislatures.

**Errors.** In all observations errors must be made. The best instruments have imperfections; and no man, however equable his temperament, can always rely on his making a proper use of his senses. As in astronomy numerical correctness in the results of instrumental measurements is of the first consequence, it is the constant care of the observer to detect and make allowance for errors. The three principal sources from which they may arise are—(1) External or incidental causes, such as fluctuations of weather, which disturb the amount of refraction; changes of temperature, affecting the form and position of instruments, &c.; (2) Errors of observation, being such as arise from inexactness, defective vision, slowness in seizing the exact instant of an occurrence, atmospheric indistinctness, &c.; and such errors as arise from slips in clamping and momentary derangements of the instrument; (3) Instrumental defects, owing to errors in workmanship, and such as arise from the instrument not being properly placed—called errors of adjustment. The first two classes of errors, so far as they cannot be reduced to known laws, vitiate the results of observations to their full extent; but being accidental, they necessarily sometimes

diminish and sometimes increase them. Hence, by taking numerous observations under varied circumstances, and by taking the *mean* or *average* of the results obtained, these errors may be made to destroy one another to a great extent, and so far may be subdued. With regard to the third class, it is the peculiarity of astronomical observations to be the ultimate means of detection of all defects of workmanship and adjustment in instruments, which by their minuteness elude every other mode of detection. It may be mentioned, however, that the method of subduing errors of the first two classes by the law of average is not applicable in all cases. In certain cases recourse must be had to the Method of Least Squares. See SQUARES, and PROBABILITY.

**Ersch, JOHANN SAMUEL**, a great German bibliographer, was born at Grossglogau, in Lower Silesia, 23d June 1766; studied theology, next history, at Halle; and after some years of journalism at Jena and Hamburg, became in 1800 librarian to the university of Jena. Three years later, he was called to Halle as professor of Geography and Statistics; and in 1808 was also appointed principal librarian. He died at Halle, 16th January 1818. Ersch was long engaged in miscellaneous bibliographical work for other scholars; but in 1818, along with Gruber, commenced the publication at Leipzig of the famous yet unfinished *Allgemeine Encyclopädie der Wissenschaften und Künste* (see ENCYCLOPÆDIA). By his *Handbuch der Deutschen Literatur seit der Mitte des 13. Jahrh.* (4 vols. 1812-14) he first established modern German bibliography in the technical sense of the word.

**Erse** (a corruption of *Irish*), a name given less frequently now than formerly to the Gaelic (q.v.) of both Ireland and the Scottish Highlands.

**Erskine, EBENEZER**, the founder of the Secession Church in Scotland, was the son of the minister of Chirnside, in Berwickshire, a scion of the noble family of Mar (q.v.), and was born June 22, 1680. He studied at Edinburgh, and, after acting as tutor and chaplain in the family of the Earl of Rothes, was licensed by the presbytery of Kirkcaldy in 1703. His abilities soon brought him into notice, and in the same year he was appointed minister of Portmunk, in Kinross-shire; and here the unction and piety which marked his discourses became exceedingly attractive to the people accustomed to the chilling 'legalism' which then predominated in the Scottish pulpit. He took a deep interest in all public questions, both in church and state, and consequently, on the rise of the Marrow Controversy (q.v.), he was one of the most prominent on the evangelical side. After having discharged the pastoral office in Portmunk for about twenty-eight years, Erskine was in 1731 translated to Stirling. Just then the patronage dispute arose, and Erskine distinguished himself by his powerful advocacy of the right of the people to choose their own pastors. Declining to receive censure for certain statements made by him on this question in a Synod sermon which had given offence to the prevailing party in the church, he, with other three ministers who adhered to him, was in 1733 suspended and then deposed from the ministry. The sentence, however, was recalled in the following year, and Erskine was invited to return. But this he declined to do unless the evils he contended against were removed. The invitation remained open until 1740, when, finding further effort hopeless, the Assembly again deposed Erskine, and ejected him from his church. On the first deposition, Erskine and those adhering to him stated a formal secession from the judicatories of the Established Church, and at Gairney Bridge, near Kinross, erected themselves into the 'Associate Presbytery.' This was

the origin of the Secession Church (see UNITED PRESBYTERIANS). In the division in 1747 of the Seceders into Burghers and Anti-burghers, Erskine took the leading part on the side of the Burghers. He was twice married, and had fifteen children. He died 2d June 1754. His *Sermons and Discourses* fill 4 vols. (Glasgow, 1762). See Lives by D. Fraser (1831) and Harper (1849); and *The Erskines: Ebenezer and Ralph*, by John Ker, D.D., and J. L. Watson (Edin. 1882).

**Erskine, HENRY**, second son of the tenth Earl of Buchan, was born in Edinburgh, 1st November 1746, and was educated at the universities of St Andrews, Glasgow, and Edinburgh. He joined the Scottish bar in 1768. His rise was immediate, and commenced, like that of his rival Henry Dundas, from his appearances in the debates of the General Assembly. Under the short-lived coalition ministry of Fox and North, he became Lord Advocate (1783), an office to which he was again appointed in 1806. In 1785 he was elected Dean of the Faculty of Advocates, but in 1796 was deposed in favour of Robert Dundas of Arniston. This mark of professional censure was intended by the Faculty to stigmatise Erskine's conduct in attending a public meeting and supporting a resolution protesting against the 'Seditious Writings Bill' proposed by the government. Lord Cockburn justly says, 'It was the Faculty of Advocates alone that snuffed.' Erskine was elected member for the Haddington burghs in March 1806, and in the following November for the Dumfries burghs. He died at Amondell, his seat near Midcaldor, 8th October 1817. During his second tenure of the office of Lord Advocate, Erskine practically carried into effect some of the legal reforms for which a pamphlet, published in London in 1807, and attributed to him on good authority, pleaded forcibly—viz. the introduction of jury trial in civil cases, and the abolition of the rule by which the fifteen judges of the Court of Session sat together. He was the author of several metrical translations from the classics, and other poems, of which the best known is *The Emigrant* (1773), inspired by the depopulation of the Highlands. Erskine's forensic style was the delight of his contemporaries, and the recorded fragments of his speeches justify his high reputation as an orator and a wit, and warrant the conclusion that, had Henry Erskine, in his own witty language, 'played at the guinea tables' in London, instead of 'at the shilling tables' in Edinburgh, he would have been no unworthy rival to his distinguished brother, Lord Erskine. See Colonel Alexander Fergusson's *Henry Erskine* (1882).

**Erskine, JOHN**, of Dun, Scottish Reformer, was born in 1509. All through the reign of Mary Queen of Scots, and through part of that of her son James, Erskine took an active share in public affairs, leading steadfast support to the reformed preachers, especially to Wishart and Knox, whilst at the same time his moderate and conciliatory temper not only secured him against the enmity of the leaders of the Catholic party, but gave him considerable personal influence in the country. He was frequently chosen to negotiate between the Reformers and the representatives of the sovereign, and to mediate between the different sections amongst the Reformers themselves. From 1560 down to about 1589, two years before his death, he held the office of superintendent for the reformed district of Angus and Mearns. Although a layman, he was elected on at least five separate occasions moderator of the General Assembly, and was one of the compilers of the *Second Book of Discipline* (1578).

**Erskine, JOHN**, Scottish jurist, was born in 1695, the son of the Hon. Colonel Erskine of 183

Carnock, Fife. He was called to the bar in 1719, but did better as a lecturer than a practitioner, having in 1737 been appointed to the chair of Scots Law in Edinburgh University. He resigned it in 1763, and died on 1st March 1768 at Cardross, near the Lake of Menteith, which estate he had purchased in 1746. His two works are still held in deserved repute—*Principles of the Law of Scotland* (1754; 17th ed. 1886), and the more important *Institutes of the Law of Scotland* (1773; 9th ed. 1871). As a legal writer, indeed, he is second only to Stair, the sterling merits both of the *Principles* and of the *Institutes* being their plainness and sound common sense.

**Erskine, JOHN, D.D.**, son of the preceding, was born June 2, 1721. He studied at the university of Edinburgh, and, licensed to preach in 1743, was appointed minister successively of Kirkintilloch (1744), Culross (1753), New Greyfriars Church, Edinburgh (1758), and the collegiate charge of Old Greyfriars (1767), where he had for his colleague Dr Robertson. In 1766 the university of Glasgow conferred on him the honorary degree of D.D. In the General Assembly he was for many years the leader of the popular or evangelical party; and between him and Principal Robertson, the leader of the Moderate party, there was a courteous and honourable friendship. Erskine's twenty-five publications are of a high order of ability. They consist of essays, letters, sermons, dissertations, and pamphlets, &c., mainly of a religious character, even when dealing with the political American controversy, on which he wrote largely. He also edited a number of British editions of works of American divines. Sir Walter Scott, in his *Guy Mannering*, gives a graphic description of his powers as a preacher. See the Life by Sir Henry Moncrieff Wellwood (1818).

**Erskine, RALPH**, brother of Ebenezer, was born at Monikrags, in Northumberland, March 18, 1685, and, after studying at Edinburgh, was ordained to the parish church of Dunfermline in 1711. Like his brother, he took part on the evangelical side in the Marrow Controversy (q.v.); and, after the formation of the Associate Presbytery, he withdrew from the communion of the Established Church, and joined the former in 1737. In the controversy concerning the burgess oath he also took part with the Burghers, and wrote several pamphlets in defence of their position. He was, however, less a controversial than a practical writer. Being a very popular preacher while he lived, his sermons were greatly prized after his death, and many of them were translated into Dutch and widely circulated in Holland. His *Gospel Sonnets* and *Scripture Songs* are well known. He died November 6, 1752. See the Life by James Fisher, prefixed to his *Practical Works* (2 vols. 1764).

**Erskine, THOMAS, LORD ERSKINE**, the youngest son of Henry David, tenth Earl of Buchan, was born in Edinburgh, 21st January 1730, and was educated at St Andrews. In 1764, much against his will, he was sent to sea in the *Tartar* man-of-war, under Sir David Lindsay. After cruising about for four years in the West Indies and on the coast of America, he obtained an ensign's commission in the 1st Royals, at a price which absorbed his whole patrimony (1768), and was for some time stationed at Minorca, where he employed his leisure time in a minute and devoted study of Shakespeare, Milton, Dryden, Pope, and other masters of English literature. On his return to London in 1772, Erskine mingled freely with the best social and literary circles, and acquired a distaste for military life, which an accidental visit to an assize court, and an interview with Lord Mansfield, turned into a determination to

prosecute the study of law. He was admitted to Lincoln's Inn, 26th April 1775; and in 1776 entered Trinity College, Cambridge, where he took an honorary M.A. in 1778, just before being called to the bar. His professional career was one of immediate and unprecedented success. Accident threw in his way a retainer in the case of Captain Baillie, lieutenant-governor of Greenwich Hospital, who was threatened with a criminal prosecution for libel, at the instance of Lord Sandwich, the First Lord of the Admiralty. Erskine's advocacy secured the discharge of the rule for leave to file an information (24th November 1778), and as he left Westminster Hall from the scene of this signal victory the attorneys flocked round him with their retainers to the number, as he afterwards used to tell, of sixty-five. The next year saw an equally successful defence of Admiral Lord Keppel against charges of professional misconduct and incompetence. In 1781 Erskine secured the acquittal of Lord George Gordon, indicted for high-treason in connection with his conduct during the notorious riots, and on this occasion delivered his first assault upon the doctrine of *constructive* treason, by which it was sought to make persons who aimed at effecting a change in the sovereign's

appointed a King?

on the special recommendation of Lord Mansfield, and at the same time was returned as member of parliament for Portsmouth. The high expectations of his friends were rudely disappointed by his first political appearance in the House of Commons, and, although he subsequently made effective and eloquent speeches, he never became a parliamentary orator. 'I'll tell you how it happens, Erskine,' said Sheridan, 'you're afraid of Pitt; and that is the flabby part of your character.' Erskine's sympathy with the French Revolution, aroused by a visit to Paris in 1791, led him to join the 'Society of the Friends of the People'—whose object was to bring about parliamentary reform—and to undertake the defence in the principal political prosecutions of 1793-94. His courageous acceptance of a retainer from Tom Paine resulted in his removal from the office of Attorney-general to the Prince of Wales, to which he had been appointed in 1786. But his speeches for this unpopular defendant, and for Frost (1793), Hardy (1794), and Horne Tooke (1794), are among the finest specimens of forensic skill, and in the language of Hardy, 'will live for ever.' Erskine's defence of Hadfield (April 26, 1800), indicted for shooting at George III. in Drury Lane Theatre, was a powerful and logical analysis of a theory of criminal responsibility in mental disease, which had hitherto done bloody duty in English courts of law. In 1802 Erskine was appointed Chancellor to the Prince of Wales, an office which had lain dormant since the time of James I., but was now revived in his favour. In 1806 he was raised to the peerage and the woolsack, but soon retired into private life. He died at Amondell, Linlithgowshire, 17th November 1823.

Erskine had married first, in 1770, Frances, daughter of Daniel Moore, M.P. for Marlow; and secondly, at Gretna Green, when he must have been about seventy, a Miss Mary Buck. He published a pamphlet on the abuses of the army in 1772; a view of the causes and consequences of the war with France in 1797; a political romance, *Armata*; a pamphlet in favour of the Greeks; and some poems.

Erskine's decisions as Lord Chancellor were styled by his contemporaries the 'Apocrypha,' and have added nothing to his permanent fame. His

reputation is purely forensic, and in this respect is unrivalled in the history of the English bar. The charm of voice and presence and gesture may have contributed something to his unique influence over judges and jurymen; but the careful student will not fail to note in his speeches the enduring qualities of genuine sentiment, profound acquaintance with life and character, singular fertility in illustration, and powers of exposition and reasoning to which the history of advocacy hardly offers a parallel. See Campbell's *Lives of the Chancellors*, vol. viii.; Fergusson's *Henry Erskine* (1882); and Duméril's *Lord Erskine, a Study* (Paris, 1883).

**Erskine**, THOMAS, of Linlathen, was born in 1788, and educated at Edinburgh High School, at Durham, and at the university of Edinburgh. He was admitted advocate in 1810, but ceased to practise after his elder brother's death gave him the family estate of Linlathen, near Dundee, and devoted himself for the remainder of his uneventful life to his favourite theological studies. He never married, but his devoted sister helped him to make his house at Linlathen a hospitable centre of Christian culture. Among his intimate friends were such spiritual leaders as M'Leod Campbell, Maurice, Stanley, Ewing, Vinet, as well as Carlyle and Prévost-Paulod. He died 20th March 1870. Erskine was brought up an Episcopalian, but in later life was at least nominally a member of the Church of Scotland. His theological opinions and religious sympathies hardly fell within the lines of the usual creed definitions, while a belief in the ultimate universal salvation of mankind and the worthlessness of miracles as evidence for inspiration were scarcely consistent with formal citizenship within any church so recently as fifty years ago. His books were *Remarks on the Internal Evidence for the Truth of Revealed Religion* (1820); *An Essay on Faith* (1822); *The Unconditional Freedom of the Gospel* (1828); *The Brazen Serpent, or Life coming through Death* (1831); *The Doctrine of Election* (1837); and *The Spiritual Order*, a posthumous work (1871). See his Letters, edited by Dr W. Hanna (1877-78).

**Eruptive Rocks.** See IGNEOUS ROCKS.

**Eryngo** (*Eryngium*), a genus of Umbelliferae, but of curiously thistle-like aspect, since the sessile flowers of the umbel form what is practically a capitulum. The large, spiny leaves recall those of holly, but have a glaucous bloom, which in some species gives the foliage an opalescent blue colour. These especially are cultivated in flower-gardens, but the young leaves of *E. maritimum* (Sea-holly) are occasionally eaten as a salad; the Mediterranean species were also valued by the ancients. Falstaff mentions the use of the candied root. An American species is also used in domestic medicine.

Sea-holly (*Eryngium maritimum*).

**Erysimum**, a genus of Cruciferae allied to Hedge-mustard (*Sisymbrium*) and Dame's Violet

(Hesperis). The seeds of *E. cheiranthoides* were formerly employed as an anthelmintic, hence the name of Worm-seed. It is also called Treacle Mustard, because an ingredient in the famous *Venice Treacle*. The seeds of *E. perfoliatum* are used as a source of oil in Japan.

**Erysipelas** (Gr., 'red skin'), an inflammatory and febrile disease of the skin, attended by diffused redness, pain, and swelling of the part affected, and in the end by either desquamation or vesication of the cuticle, or scarf-skin, in the milder forms, and by suppuration of the deeper parts in the severer varieties of the disease (*phlegmonous erysipelas*). It is characterised by a marked tendency to spread over the skin from the place where it arises. Erysipelas affects, in a large proportion of instances, the face and head; it is apt to be attended with severe fever, and often with great disorder of the nervous system, arising in some instances from inflammation of the membranes of the brain. In other parts of the body, severe or phlegmonous erysipelas is apt to be succeeded by protracted and exhausting suppurations, and sometimes by diseases of the bones, or inflammations of the internal organs. Erysipelas in its severer forms usually commences in a wound or sore, and is extremely apt to be communicated to any one with a breach in the continuity of the skin who comes in contact with a case of the disease. Epidemic outbreaks of erysipelas used therefore to be common and disastrous in surgical hospitals; but since the general introduction of antiseptic treatment they have almost disappeared. Erysipelas is very apt to recur in a person who has been attacked once or oftener; and this is especially true of the form which affects the face. It is believed to be due to the presence of a micrococcus in the affected tissues. It is seldom that depletion is allowable in erysipelas, but the bowels should be well cleared out in most cases, and a Diuretic (q.v.) given, after which the treatment consists for the most part in watching narrowly the progress of the case, keeping up the strength as well as possible, and obviating special dangers as they occur. In some cases iron is used as a specific remedy in the form of large doses of steel drops. It is of course important that no one liable to the disease should be exposed to the infection. St Antony's Fire (see ANTONY) and Rose are common names for erysipelas.

**Erythema** (Gr. *eruthainō*, 'I redden'), a name applied to certain skin diseases, but scarcely used by any two writers on the subject in exactly the same sense. It is used, generally speaking, of eruptions where there is circumscribed or diffuse redness, without any break in the skin surface, with or without elevation of the affected part. The chief forms described under the name are rashes like a persistent blush occurring in the course of some fevers, in consequence of drugs, or without ascertainable cause, but usually of short duration: *E. multiforme*, where the eruption is raised, and generally in the form of papules, rings, or irregular lines; *E. nodosum*, consisting of dark-red, painful swellings, usually on the front of the leg, and believed to be connected with the rheumatic diathesis; and cases closely resembling erysipelas, except that the symptoms, both local and constitutional, are very much less severe. The cause, if known, should be treated; but no general rules for treatment can be laid down.

**Erythraea**. See CENTAURY.

**Erythrina**. See CORAL FLOWER.

**Erythronium**, a genus of Liliaceae. *E. dens canis*, the Dog-tooth Violet, so called because of the resemblance of its little white bulbs to dogs' teeth, is a well-known ornament of English flower-

borders in spring. It is a native of southern Europe and Siberia, where it is used as a source of food, and also medicinally.

**Erythrophleum**, a genus of leguminous trees (sub-order Mimoseae). The red juice of the bark of *E. guineense* is administered in ordeals and used for arrow-poisoning by the natives of Guinea and the Gold Coast.

**Erythroxylaceae**, a small order of dicotyledonous trees or shrubs, chiefly South American, allied to Malpighiaceae. *Erythroxylon suberosum* is a red dye-wood of Brazil. That of *E. hypericifolium* is the *Bois d'huile* (Oil-wood) of Mauritius. The most important member of the order is, however, *E. coca*. See COCA.

**Eryx**, the ancient name of a mountain in the NW. of Sicily, near Drepanum (mod. Trapani), on which stood a famous temple of Venus, who was thence called *Erycina*.

**Erzberg**. See EISENERZ.

**Erzerûm**, an important town in Turkish Armenia, in 39° 55' N. lat., and 41° 20' E. long., not far from the Kara-Su, or western source of the Euphrates. It is situated on a high but tolerably well cultivated plain, 6200 feet above the level of the sea, surrounded by mountains. The climate is cold in winter, but hot and dry in summer. Erzerûm is the residence of English, Russian, German, and French consular agents; and its population is estimated at 40,000, consisting of 30,000 Turks, 8000 Armenians, and 2000 Persians, who carry on a brisk trade, and have thus attained to a degree of prosperity unusual in the East. The copper and iron wares of Erzerûm have acquired a wide celebrity. Situated at the junction of the important highways leading from Trebizond, Transcaucasia, Persia, Kurdistan, Mesopotamia, and Anatolia, Erzerûm forms an entrepôt of commerce between Europe on the one hand and the interior of Asia, and particularly Persia, on the other. The streets, the houses of which are built chiefly of volcanic stone cemented with mud, are narrow, crooked, and filthy; and ruins of fortifications and of buildings formerly magnificent everywhere meet the eye. The town consists of the fortress, strictly so called, and four suburbs. The fortress, which is inclosed by a high wall, has, on the west, a citadel (El-Kal'a), with many curious monuments, and a mosque of Christian origin. The fortress also contains fifteen other mosques, the residence of the chief-magistrate, some caravanserais, and a few elegant houses belonging to the higher order of officials and Mohammedan merchants. The suburbs boast twenty-four mosques, several Armenian churches, and a number of large bazaars and caravanserais. Erzerûm imports shawls, silk goods, cotton, tobacco, rice, indigo, &c., and exports corn, sheep and cattle, horses, mules, and gall-nuts. The principal trades carried on are tanning, dyeing morocco leather, and blacksmiths' and copper-smiths' work. But since Russian Transcaucasia has provided a safe trade-route to Persia, the prosperity of Erzerûm has greatly suffered. It was first conquered by the Arabs in 700, but retaken by the Byzantines fifty years later. After various vicissitudes, it fell into the hands of the Seljuks; the Mongols took it in 1241; and finally, in 1517, it passed into the possession of the Turks. It still, however, continued to be the most important city in the country, and at the commencement of the 19th century had a population of 100,000 inhabitants. In the war of 1829, between the Turks and Russians, the taking of Erzerûm by Paskievich decided the campaign in Asia. Erzerûm was an important military centre during the wars of 1854-55 and 1877-78, and much hard fighting was done in its neighbourhood. In December 1877 the

Russians closed round the city, already hard pressed, and reduced its defenders to the utmost distress; in February 1878 it was surrendered to Russia, who held it till October, when it was restored to the Turks. See CURZON, *Armenia* (1854); NORMAN, *Armenia and the 1877 Campaign* (1878).

**Erzgebirge** ('Ore Mountains'), the name given to the chain of mountains, rich in metals, stretching SW. and NE. for 96 miles on the confines of Saxony and Bohemia, from the valley of the Elbe to the Fichtelgebirge. In the south it rises to a height of from 2500 to 3300 feet, forming a steep wall of rock; in the north it forms broad, slaty plateaus, broken by deep valleys, and gradually slopes down towards the level districts of Altenburg and Leipzig. Many of these valleys are well wooded and romantic, and occasionally fertile and thickly peopled, being watered by the Mulde, the Pleisse, and their numerous tributaries. The chain rises to its highest elevations in the so-called 'Saxon Siberia,' over against Zwickau. Here, in 12° 54' E. long., stands the town of Gottesgabe, the highest in Germany, at an altitude of 3363 feet; and here, too, are the loftiest peaks of the range (Keilberg, 4032 feet; Fichtelberg, 3980; Spitzberg, 3675). The Erzgebirge is chiefly of the gneiss-granite formation, with argillaceous and micaceous slates, porphyry, and basalt. Silver and lead are the principal metals; next come tin, iron, cobalt.

**Esaias.** See ISAAH.

**Esarhaddon.** See ASSYRIA.

**Esau,** the eldest son of Isaac, and twin-brother of Jacob. See JACOB, EDM., JEWS.

**Esbjerg,** a port of Denmark, 56 miles W. of Fredericia by rail, with a large export trade in cattle, &c., mostly to England. Its harbour, the only one of importance on the west coast of Jutland, was constructed by the state at great expense in 1868-74; and in 1887 an annual subsidy of about £7000 was granted by government for steamship communication with Britain. Pop. (1880) 1529.

**Escalade** (Lat. *scala*, 'ladder'), in siege operations, a method of gaining access to the enemy's works; passing ditch, curtain, bastions, by means of ladders. See FORTIFICATION, SIEGE.

**Escarp'.** See FORTIFICATION.

**Escarpment,** a long line of cliff, formed by the outcrop of a relatively hard stratum of rock interbedded amongst more yielding strata, the dip or inclination of which is generally gentle. This structure is the result of denudation—the hard rock projects simply because it has yielded less readily to the agents of erosion. In a country composed of an alternation of such relatively hard and soft rocks, dipping in one and the same direction, we usually meet with a succession of escarpments, with their steep faces all turned towards the direction to which the strata rise, while the ground falls away with a gentle slope in the direction of the dip or inclination of the beds.

**Escars.** See ASAR.

**Eschar** (Gr. *eschara*), a slough or portion of dead or disorganised tissue, is commonly applied to artificial sloughs produced by the application of caustics. *Escharotic* means causing an eschar.

**Eschatology** (Gr. *eschatos*, 'last,' and *logos*, 'a discourse'), the doctrine of the last things, a theological term for what Scripture reveals and Christian speculation has concluded about a future state. But although the term is thus limited, an eschatology existed among all the great nations of antiquity, dark and ill defined as in the Greek, or elaborate as in the Egyptian religion. Together with it grows up more or less definitely the idea of retribution. For an account of the more elementary

forms of this conception, see TRANSMIGRATION. Protestant eschatology is generally confined in practical discourses to a consideration of these four last things—Death, Judgment, Heaven, and Hell (see IMMORTALITY, RESURRECTION, DEVIL, and HELL). The principal religious parties which do not recognise eternal punishment as a Scriptural doctrine are treated at UNIVERSALISM and CONDITIONAL IMMORTALITY; the question of an intermediate state, at PURGATORY. See also MILLENNIUM.

**Escheat** (Fr. *échoir*, from Lat. *cadere*, 'to fall or happen'), an incident of the feudal law whereby, when there was no tenant qualified to perform the services, land reverted to the lord. In England, escheat took place *per delictum tenentis*, as e.g. when the tenant was convicted of a capital felony; this kind of escheat 'with attainder' was abolished in 1870, as also the Forfeiture (q.v.) of land to the crown for high-treason (see ATTAINDER). According to the existing law, a criminal's property is forfeited only in so far as may be necessary for the purpose of making compensation; but the old doctrine of 'corruption of blood' is now entirely done away; no person is barred by the crime of his ancestor from succeeding to property. Escheat still takes place *per defectum sanguinis*, for want of heirs, when the owner (the feudal tenant) of land dies intestate, leaving no heir; in such case the feudal superior (usually the crown) may claim the land. When land falls to the crown, the 'prerogative of grace and bounty' is sometimes exercised in favour of persons having claims on the deceased; subject to this prerogative the land becomes part of the crown-lands, and the profits are carried to public revenue.

Escheat in Scotland is of two kinds: (1) The total forfeiture to the crown of all property heritable and movable belonging to a person who has been convicted of treason. (2) It signifies the forfeiture of goods by a debtor who has failed to make payment of debt in obedience to legal Diligence (q.v.). This species of escheat for debt was abolished by 20 Geo. II. chap. 50. It was of two kinds: single escheat, and liferent escheat. By the former, all the debtor's movables were forfeited to the crown; by the latter, the annual profits of the debtor's estate were forfeited to the superior. Single escheat still exists in Scotland as a punishment of crime. In all capital convictions it is ordered that the prisoner's 'whole movable goods and gear be escheat and inbrought to his majesty's use.' In cases of debarment, bigamy, perjury, and some others, single escheat is imposed by statute as a portion of the penalty on conviction. Single escheat also falls upon denunciation for outlawry; and, if the rebel continues for a year under denunciation, his liferent escheat falls to his superior.

In the United States, the rules of feudal tenure are, for the most part, obsolete; but all property, real or personal, which is left without a legal owner, is claimed by the state in which it is situated.

**Eschenbach, WOLFRAM VON.** See WOLFRAM VON ESCHENBACH.

**Eschscholtz Bay,** the innermost part of Kotzebue Sound, in Alaska, barely outside the polar circle. It was named after the naturalist Johann Friedrich Eschscholtz (1793-1834), who sailed as surveyor with Otto von Kotzebue.

**Eschscholtzia,** a genus of Papaveraceæ, of which *E. californica* and other species are common as showy garden annuals.

**Eschwege,** a town in the Prussian province of Hesse-Nassau, on the Werra, 40 miles ESE. of Cassel by rail. It has manufactures of woollen, cotton, and linen fabrics, of machines, and of

tobacco; also tanneries, and some trade in fruit and pork, and agricultural produce. Pop. 9492. The town was twice plundered and once burned during the Thirty Years' War.

**Eschweiler**, an industrial town of Rhenish Prussia, 8 miles ENE. of Aix-la-Chapelle, has important iron, zinc, and tin works, machine-shops, manufactories for making copper plates, needles, wire, gas-pipes, and firebricks, besides tanneries and breweries. In the vicinity are productive coal-mines. Pop. (1875) 15,540; (1885) 16,889.

**Escobar y Mendoza**, ANTONIO, Spanish casuist, was born at Valladolid in 1589. Entering the order of the Jesuits in 1604, he became celebrated as a preacher and writer. At his death in 1669 he left more than 40 vols. in folio, mostly in theology and morality, the principal being the casuistical *Liber Theologicæ Moralis* (1646), which has several times been printed.

**Escorial**, or, less correctly, **ESCURIAL**, a royal palace, mausoleum, and monastery of Spain, 31 miles NW. of Madrid, on the south-eastern slope of the Sierra Guadarrama, at an altitude of 3700 feet. This immense pile of buildings, built of dark-gray granite, has a stern, austere, forbidding appearance, which is not at all relieved by the bleak, wind-swept, mountainous region in which it stands. It owes its existence to Philip II., who erected it partly to provide a royal burying-place for the kings of Spain, partly to commemorate his victory over the French at St Quentin on St Lawrence's day, 10th August 1557. Its general shape is that of a quadrangular parallelogram, 706 feet long by 550 broad, with a smaller square projecting from the east side. The current belief is that it was planned to represent a gridiron, the object upon which St Lawrence was martyred; but this has been questioned. At anyrate, each corner of the parallelogram is fenced with a tower, about 200 feet high; and above the church, in the centre of the pile, rises a cupola, its summit 312 feet from the floor. The first stone of the edifice was laid in 1563, the architect being Toledo, after whose death in 1567 his pupil Herrera carried on the work to its completion in 1584. The finest individual building is the church, a square basilica, in the shape of a Greek cross, and in the Doric order of architecture. It was formerly rich in paintings; and, although in 1837 a hundred of the best were removed to Madrid, there still remain specimens by Coello, Carabajal, Tibaldi, Zuccaro, Luca Giordano, Trezzo, Zurbaran, Ribera, Tintoretto, Titian, and Veronese. The Pantheon, or royal mausoleum, an octagonal chamber beneath the church, contains the bones of the kings of Spain from Charles V., father of Philip II., onwards (except Philip V. and Ferdinand VI.) to Alfonso XII., with queens, regents, and mothers of kings; the rest of the royal family, with Don John of Austria, are buried in the 'Panteon de los Infantes.' The library, once one of the richest in Europe, but greatly diminished by a fire in 1691, and by thefts by the French soldiery in 1808, still contains 32,143 vols. and 4611 valuable MSS., including 1905 written in Arabic. In the palace the most interesting apartment is the cell of Philip II., in which he spent his last days. The Escorial was again greatly injured by fire in 1872.

**Escort.** See CONVOY.

**Escrow.** See DEED.

**Escutcheon** (Fr. *écusson*, in contradistinction to *écu*, an ordinary shield), in Heraldry, the shield on which arms are painted; also a small representation of the knightly shield used as an armorial charge, and generally reckoned among the sub-ordinaries. The name inescutcheon in modern

heraldry is used where there is more than one such charge. From the escutcheon as a charge must be distinguished the escutcheon *en surtout*, charged with some particular coat, and placed in the centre of a heraldic shield, which is much used in marshalling of arms in regal, continental, and Scottish heraldry. Such an escutcheon, placed with the arms of an heiress in the centre of her husband's coat, is known under the name of an escutcheon of pretence. The escutcheon of pretence used in this way is unknown out of Britain.

**Esdraelon**, or PLAIN OF JEZREEL, a broad valley of Palestine, constituting the basin of the Kishon, extends westwards from Mount Hermon to the slopes of the Carmel range. Although it was a flourishing and fertile region in antiquity, it fell in modern times out of cultivation, and so recently as 1867 was annually harried by Bedonins; now, however, it is once more in the highest state of cultivation. Here Gideon defeated the Midianites, and here in 1799 the Turks were defeated by the French. See Laurence Oliphant's *Haiju* (1887).

**Esdras**, Books OF. The word *Esdras* is the Greek form of Ezra, and indicates that the books so named do not exist in Hebrew or Chaldee. What is now usually called 1st Esdras is in the oldest Greek texts also called 1st Esdraz; what is there 2d Esdraz being our canonical Ezra. The oldest form of our 2d Esdraz, though originally written in Greek, is in Latin only. Hence it has been proposed to call our 1st Esdraz the *Greek Esdraz*, and our 2d the *Latin Esdraz*. The Council of Trent, though recognising most of the Apocrypha as canonical, did not so regard either 1st or 2d Esdraz of the Apocrypha (their 1st Esdraz being Ezra, and their 2d, Nehemiah). Yet in the authoritative Roman Septuagint of 1587 1st Esdraz stands before the canonical Ezra; and modern Vulgates print 1st and 2d Esdraz along with the Prayer of Manasseh as a kind of separate appendix. In all the earlier editions of the English Bible the order of the Vulgate is followed. The Geneva Bible was the first to adopt the classification now used, according to which Ezra and Nehemiah give their names to two canonical books, and the two apocryphal become 1st and 2d Esdraz; and in the sixth article of the Church of England 1st Esdraz is called the 3d book of Esdraz. As regards the *first* book of Esdraz, it is for the most part a transcript—and not a very accurate one—of Ezra and a portion of Nehemiah, together with the last two chapters of 2d Chronicles. Josephus quotes it extensively in his *Antiquities*, even when it contradicts Ezra proper, a fact which indicates that it was highly valued by the Jews. The book seems to have been written rather with a hortatory than a purely historical aim, in order to stimulate to the more zealous keeping of the law. The author was probably a Jew, writing in Egypt possibly as early as 146 B.C., and certainly a century before Christ. The familiar phrase, *Magna est veritas et prevalebit* ('Truth is great, and will prevail'), is taken from the 41st verse of the 4th chapter of this book, where, however, the text reads *prevaleat*. The *second* book of Esdraz, or Revelation of Esdraz, is wholly different in character from the first. It consists of a series of angelic visions and revelations made to Ezra regarding the mysteries of the moral world and the final triumph of the righteous. It might fairly be called the apocalypse of Ezra, had not Tischendorf published a later and inferior work under this title in 1866. The book is not all by one hand. The oldest part—chaps. iii.—xiv.—seems to have been written by a non-Christian Jew of Alexandria about 81–96 A.D.; while chaps. i. ii. xv. xvi. are the work of a Christian Jew of

Alexandria as late as 263 A.D. See Fritzsche's *Handbuch* to the Apocrypha; and Lupton in the *Speaker's Commentary* (1888).

**Esenbeckia**, a genus of Rutaceæ. The bark of *E. febrifuga* of Brazil was formerly used as a substitute for Cinchona.

**Eserin**, the alkaloid of the Calabar Bean (q.v.).

**Esher**, a pretty village of Surrey, on the Mole, 15 miles SW. of London by rail. Here are Esher Place, a brick gate-tower of Wolsey's palace, and Clarendon (q.v.). Pop. of parish, 1993.

**Esk** (Cymric *wysg*, Gael *uisge*, 'water,' akin to *Eze*), the name of several small Scotch rivers. The Dumfriesshire Esk, formed by the Black and White Esks (12 and 14 miles long), runs 22 miles south-south-eastward, next 5 furlongs along the Border, and lastly 8 miles south-south-westward through Cumberland, till it falls into the head of the Solway Firth. It passes Langholm and Longtown, receives the Tarras, Liddel, &c., and affords capital fishing.—The Edinburghshire Esk, formed by the North and South Esks (17 and 19 miles long), flows 4 miles northward to the Firth of Forth at Musselburgh. Its scenery is very pretty, the northern branch passing Habbie's Howe, Roslin, Hawthornden, and Melville Castle; the southern branch Dailionsie Castle and Newbattle Abbey; and the two uniting in Dalkeith Park. The fishing is recovering from the injurious effects of the paper-mills.—Of the two Pofarshire rivers, the South Esk runs 49 miles south-eastward and eastward to the North Sea at Montrose, and the North Esk 29 miles south-eastward (over the last 15 along the Kincardineshire boundary), until at a point 4 miles N. of Montrose it likewise falls into the North Sea. Both traverse fine scenery; both afford first-rate sport; and both give earl's titles to branches of the Carnegie family.—Southesk (1633) and Northesk (1692).

**Esker**. See ÅSAR, and GLACIAL PERIOD.

**Eski-Djumna**, a town of Bulgaria, 20 miles WSW. of Shumla, with a noted fair in May. Pop. 10,038.

**Eskimo**, the name of a nation which constitutes the aboriginal inhabitants of the whole northern

miles of the nearest Asiatic coast. Only in the southern limits of the American Eskimo region do their abodes touch the northern limit of wooded land, while on the other side their tracks have been met with as far as Arctic discoverers have hitherto advanced towards the pole. They prefer, however, the vicinity of the seashore, from which they rarely withdraw more than 20, and hardly ever 80 miles. Their number is not ascertained with exactness, but it scarcely amounts to 40,000. Nevertheless they are scattered as the sole native occupants of regions stretching from east to west as far as 3200 miles in a straight line, to travel between the extreme points of which would necessitate a journey of no less than 5000 miles. This distance, taken in connection with their homogeneous nature and manners, makes their small bands the most thinly scattered people of the globe. Their extraordinary persistency in maintaining their language and habits must be due to the difficulties they have had to face in procuring subsistence where no other nation can live, and to the consequent obligation of preserving as a precious inheritance all the contrivances, and of maintaining the hardness, developed by their ancestors during their first settling on the Arctic shores.

As to their bodily form, they used to be classed most generally among nations of the Mongolian stock, but now they are considered by some almost as much akin to the American Indians, the coast tribes serving as an intermediate link. Their height nearly equals the average of the North-west Indians. They appear comparatively taller sitting than standing. Their hands and feet are small, their faces oval, but rather broad in the lower part; their skin is only slightly brown; they have coarse black hair and very little beard. The skull is high and mesaticephalic, with a tendency in some individuals to the dolichocephalic type.

Though occasionally they find food by pursuing the chase on land, and by fishing, the Eskimos get their subsistence mostly from hunting by sea, using for this purpose their skin-boats where the sea is open, and their dog-sledges on the ice. From the skin, blubber, and flesh of the seal and the cetaceous animals, they procure clothes, fuel, light, and food. Their most interesting as

well as important invention for hunting is the well-known small skin-boat for one man, called a *kayak*. It is formed of a framework covered with skin, and, together with his waterproof jacket, it completely protects the man against the waves, so that he is able to rise unhurt by means of his paddle, even should he capsize. A Greenland's kayak is almost 18 feet long and 2 feet broad, and can carry 200 lb. besides the man. The special weapon of the kayak is the large harpoon, connected by a line with an inflated bladder. The hunter throws it when but 25 feet from the seal, and at once drops the bladder overboard, thus retarding the speed of the wounded animal, which runs off with it until finally killed by a lance-thrust.

In winter the Eskimos are undoubtedly stationary in their habits. But during the summer, when sufficient open water is found, they roam about in their large skin-boats, the *umaks*, which are from 25 to 37 feet long, 5 feet broad, and  $2\frac{1}{2}$  feet deep, and are capable of carrying from  $1\frac{1}{2}$  to 3 tons—

Eskimo Winter Station, Greenland.  
(From a Drawing by the Author.)

coast of the American continent down to 60° N. lat. on the west, and 55° on the east, and is spread over the Arctic Islands, Greenland, and about 400

large skin-boats, the *umaks*, which are from 25 to 37 feet long, 5 feet broad, and  $2\frac{1}{2}$  feet deep, and are capable of carrying from  $1\frac{1}{2}$  to 3 tons—

the tent, with all the necessary implements for the summer household.

The winter dwellings vary with regard to the materials of which they are built, as well as in their form. In the farthest west they are constructed mostly of planks, covered only with a layer of turf or sod; in Greenland the walls consist of stones and sod; in the central regions the houses are formed merely out of snow. In Alaska the interior is a square room, surrounded by the sleeping-places, with the entrance on one side, while a hearth with wood as fuel occupies the middle of the floor. In Greenland the room is heated only by lamps, and the sleeping-places or family stalls are arranged in a row occupying one of its sides. The house for this reason is lengthened proportionally to the number of its inhabitants. Nowadays, however, the houses are not made so long as formerly—a curious fact corresponding to the disuse of the Indian 'long houses,' and like it a result of contact with civilisation. In East Greenland, in the autumn of 1884, the isolated pagan tribe of Angmagssalik numbered 413 individuals, inhabiting thirteen houses, of which one had fifty-eight inmates; while on the semi-civilised west side, where formerly houses with fifty persons also were frequent, the average number has now sunk to ten persons per house. In Alaska, on the other hand, the wintering stations have communal buildings for common use and public assemblies, the so-called *kages* and *kashim*. In East Greenland a house of ordinary size accommodated thirty-eight persons, divided into eight families, each having its part of the sleeping-bench assigned and separated from the next by a low curtain, but all comprised in the same one room of the whole dwelling, which was 28 feet long, 15 feet broad, and 6½ feet high along the ridge line. The number of inhabitants at an Eskimo station is most frequently under forty, but in rare cases more than two hundred are found. A funnel-shaped, half-underground passage forms the entrance of the narrow dwellings.

The dress is almost the same for women as for men, consisting of trousers or breeches and a tunic or coat fitting close to the body, and covering also the head by a prolongation that forms the hood. For women with children to carry, this hood is widened so as to make it an excellent cradle, the *amaut*. Tattooing has been general among all the tribes, but only in the west is found the curious custom of wearing labrets, or lip-ornaments of bone or stone, inserted in holes of the lip, pierced for the purpose. The ordinary materials of which clothes are made are the skins of seals, land animals, and birds. Besides these, the intestines of seals are utilised in manufacturing an outer clothing used for waterproof coats.

The Eskimo language exhibits in a high degree the polysynthetic structure of the American tongues, characterised by the power of expressing in one word a whole sentence in which are embodied a number of ideas which in other languages require separate words. This is effected by means of radical words, to which affixes or imperfect words are attached. The Greenland dictionary contains 1370 such radicals and about 200 affixes, of which from one to ten, rarely more, can be appended to one of the former. As far as a rough estimate seems to prove, in many cases a radical may in this way be made the foundation of, strange to say, many thousands of derivatives, and a word can be composed which expresses with perfect distinctness what in our civilised languages might require twenty words. In Greenland and Labrador the missionaries have adapted the Roman letters for reducing the native language to writing. The printed Greenland literature, including what has been published by the Moravian

Brethren, amounts with pamphlets and the like to what might make seventy to eighty ordinary volumes. About half of it is of a religious character. A sort of journal has been published annually since 1861, containing many articles by native writers. The Labrador literature, as far as we know, contains about ten books. The two dialects, of course, show some difference, but probably less than, for instance, Danish and Swedish. A similar difference may prevail between the idioms of Greenland and Alaska, without rendering them mutually unintelligible. Works in which the Eskimo language is occasionally treated are numerous.

As to *sociology*, it is doubtful whether an organisation like that of the Indian 'families,' in a stricter sense, has been discovered among the Eskimos, although a tendency to it certainly may be traced. Its maintenance must probably have been found incompatible with the extraordinary dispersion and isolation of the race. But a division into tribes, each with their separate territories, is ascertained as actually existing. The tribe again is divided into groups constituting the inhabitants of the different wintering-places. Finally, in the same station, the inhabitants of the same house are closely united with regard to common housekeeping. In this, and perhaps similar ways, their general communism in living, characteristic of their stage of culture, is governed by rules for partnership in householding, for distribution of the daily game during the winter, and for the possessions of the individual, the family, the housemates, and the place-fellows. One of the oldest, and most respectable men, called in Greenland *itok*, in Labrador *angajorkuk*, is obeyed as chief of a house or wintering-place, although his authority, perhaps, may rest on tacit agreement only. In a similar way, more or less public assemblies constitute councils, and may be considered the courts of justice. Social organisation has been more highly developed in Alaska than in Greenland, altogether apart from the later European influence.

The inhabitants of Danish West Greenland, numbering about 10,000, the greater part of the Labradorians, and the Southern Alaska Eskimos are Christianised. As for the rest, the religion of the Eskimos is what is generally designated as Shamanism. According to the traditions of the Greenlanders, their heathen ancestors had a very distinct belief in the existence of the soul as independent of the body, and able to continue its existence after death. The souls of this deceased were venerated as guardian spirits of their surviving offspring, but besides them numbers of invisible rulers, called *inuk*, or owners of things, filled the universe. The religious observances, with the aim of propitiating or calling for assistance on these supernatural powers, consisted of *serranek* ('prayer'), *kerranek* ('invoking'), and the use of amulets. Moreover, many regulations were observed concerning modes of life, fasting, abstinence, and sacrifices (*atsirinek*). Some people were endowed with a peculiar skill (*nulussaerunek*, 'clairvoyance') in discerning the spiritual beings and influencing them. The highest stage of this kind of knowledge was that of the *Angakoks*, or Shamans, who invoked their guardian spirits (*tornat*) by means of *torninek* ('conjuring'). A supreme being, *tornarsuk*, ruler of the *tornat*, is also spoken of, but in very indistinct terms. In Alaska religious festivals, performed by large assemblies, and with the use of masks, were held in high esteem as a means of propitiating the invisible powers. The opposite of religious actions and *angakok* wisdom was *itiscenek* ('witchcraft'), also consisting without doubt in an application to

supernatural powers, but that secretly, for selfish purposes, to the detriment of others.

The Christianised natives still preserve their ancient folklore. It represents at the same time their original poetry, religious ideas, and history, praising the deeds of their great men in braving the dangers to which their race has been continually subjected. The *Tales and Traditions of the Eskimo* (Edin. 1875), collected and translated by the writer of this article, comprise a collection of 150 tales founded on versions supplied by about fifty narrators from different parts of Greenland, and a few from Labrador. A valuable collection has since been acquired from East Greenland, some tales from Baffin Land, and a number of the simplest fragments of the same from Behring Strait.

The name Eskimo is said to be formed by corruption out of an Indian word signifying 'eaters of raw meat.' They call themselves *Inuit*, in Greenland partly *Kalallit*. Their origin most generally has been derived from Asia, but now they are believed by some to have come from the interior of America, and, following the river-courses, to have arrived at the Arctic Sea, where they have developed their abilities as an Arctic coast people. The writer is inclined to believe that this development has issued from the north-western corner of America, while others suggest that the same process has been going on around Hudson Bay too. In Alaska they almost appear to form a continuation of the North-west Indians—a gradual one, as towards the north and east they have become a more exclusively maritime and Arctic people; their relation to the inland people takes a decidedly hostile character, and murderous fights have been frequent on the borders of the Mackenzie and the Coppermine rivers. The Eskimos may now be divided into the following groups with a roughly estimated census: (1) The Western Eskimos, inhabiting the Alaska Territory and the Asiatic side of Behring Strait, rated at 13,200 souls; (2) the Mackenzie Eskimos, or Tchiglit, from Barter Island to Cape Bathurst, 2000; (3) the inhabitants of the central regions, including the Arctic Archipelago, 4000 (?); (4) the Labradorians, 2200; (5) the Greenlanders, upwards of 11,000. A side branch, moreover, inhabits the Aleutian Islands, numbering 2400; their habits and mode of life are almost like those of their Inuit neighbours, but their language, except its grammatical system, differs widely from the Eskimo.

As to the influence of the Europeans, the missionary work is mentioned above. In Greenland much care has been bestowed by the Danish government to avert the hurtful influence of contact with civilised strangers. But communism forms an essential element in the native life as does even hunting, and, since the traditional obligations which counterbalanced its ill effects have fallen gradually into desuetude, the general result has been impoverishment. The curtailment of the houses mentioned above is owing to a rather ineffectual attempt by the natives themselves to escape this calamity.

See the article GREENLAND; also, for the books upon the Eskimo, Pilling's 116-page *Bibliography of the Eskimo Language* (Washington: Government Printing Office, 1888). Among the books enumerated therein may be selected those by Beachy, Craws, Dall, H. Egede, O. F. Hall, Parry, Petitot, Ray, J. Richardson, H. Rink, and J. Ross. Besides these may be mentioned two, not in Pilling, *Memoirs of Hans Eendrik, the Arctic Traveller*, translated from the Eskimo original by Dr H. Rink (Lond. 1878); also Dr H. Rink, *The Eskimo Tribes* (in English, Copenhagen and London, 1887).

**Eskimo Dog**, a half-tamed variety widely distributed in the Arctic regions, and indispensable for drawing the sledges. They are strong and

powerful, like shepherds' dogs in form, with long black and white, brown, or dingy white hair.

Eskimo Dog.

Often ill fed and overworked, they retain much of the original wildness of their wolf ancestry, and are subject to a fatal epidemic which kills them in large numbers, to the serious impoverishing of their owners.

**Eskei-Sagra**, a town of Eastern Rummelia, at the southern base of the Balkans, 70 miles NNW. of Adrianople. It was almost destroyed during the Russo-Turkish war of 1877-78, and the population has dwindled from 20,000 to 10,000.

**Esla**, a river of Spain which rises in the Cantabrian Mountains, and flows SSW. through Leon, joining the Douro near the frontier, after a course of 160 miles.

**Esmeraldas** (Span., 'Emeralds'), the most northerly maritime province of Ecuador, with a climate hot, moist, and on the coast malarial, and still largely covered with dense forest. Area, 5200 sq. m.; pop. (1885) 11,146.—The capital, Esmeraldas (pop. 3000), stands 10 miles from the mouth of the river of the same name, which is navigable to this point for ships drawing 16 feet of water.

**Esné** (hieroglyphic *Sne*, Gr. *Lutopolis*—the city of the *Latus nobilis*—the fish there worshipped) is a considerable town of Upper Egypt, and is situated on the left bank of the Nile, in 25° 15' N. lat., 36 miles above Luxor. It contains about 7000 inhabitants, including many Copts and a large colony of dancing-girls, and has manufactories of fine cotton, shawls, and pottery. Indigo dyeing is a staple industry, and until the Egyptian troubles of 1881 and following years there was a considerable trade with the Soudan. The climate is considered particularly healthy, and invalids are frequently ordered there by the native doctors. The ancient temple, dedicated to the god Khnum, is buried beneath the accretions of the modern houses, except the noble portico or hypostyle hall, of 24 columns, four deep, which was excavated to the pavement by Mohammed Ali, to serve as a gunpowder cellar. Of the older temple behind nothing is known, but Champollion ascribed it to Thothmes III. The back of the portico of the temple of Khnum presents the name of Ptolemy Philometer; but the rest is more modern, and belongs to the time of the Cæsars. The sculptures are poor in design and execution. It has a Roman zodiac like that of Dendera, formerly thought to be of the most remote antiquity. A smaller temple, with a zodiac, erected in the reign of Ptolemy Evergetes, formerly stood at Ed-Deyr, 2½ miles N. of Esné, but has been destroyed. At Esné is also a stone quay bearing the name of M. Aurelius. This city

was the capital of a nome, and the coins struck in it in the reign of Hadrian, 127-128 A.D., represent the fish latus.—Champollion, *Not. Descr.*; Wilkinson, *Anc. Egyptians*; Mariette, *Mon. of Upper Egypt*; Lane-Poole, *Egypt*.

**Esocidæ.** See PIKE.

**Esoteric** (Gr.) is a term derived from the ancient mysteries, in which it was applied to those doctrines that were designed for the initiated, in contradistinction to those that were imparted to the uninitiated, which were termed *exoteric*. It is now used in various relations of an analogous kind. For Esoteric Buddhism, see THEOSOPHY.

**Espalier**, a term borrowed from the French, and signifying a railing on which fruit-trees are trained as on a wall. Such railings are very variously constructed—sometimes of wood, sometimes of iron, sometimes of upright rails held together by a horizontal rail at top, sometimes chiefly of horizontal rails with upright posts for their support. Espaliers may be very conveniently and cheaply made of strong iron wire, sustained by upright iron or wooden posts, as in ordinary wire-fences. They vary in height from 4 to about 8 feet, according to situation and the size of the garden. On the Continent they are often constructed horizontally or at a more or less oblique angle to the sun at a few feet above the ground; but, although their introduction in this form into British gardens has been recommended by some writers, they have only been adopted here and there experimentally and with no satisfactory result. They have the advantage of securing the fruit in a great measure from the effect of winds, which often shake off great part of the crop of standard trees whilst still unripe; and owing to the full exposure to sun and air excellent fruit is produced, although there is no reflected heat as from a wall, which is therefore still superior. Espaliers are very common in gardens in Britain, and add at once to the beauty and the productiveness of a garden, the ground not being overshadowed as by standard trees, although, of course, the roots of the trees render it unsuitable for many crops to some distance on both sides of the espalier. Espaliers are often used to separate flower-borders from plots occupied by culinary vegetables. Apples and pears are considered more suitable for espaliers than any other kinds of fruit-trees commonly cultivated in Britain. The treatment is generally similar to that of wall trees, but the training is usually by horizontal branches. It is not unusual, when trees have become old and their branches thick and firm, to dispense with great part of the rails necessary in their earlier training.

**Espartero**, BALDOMERO, Duke of Vittoria, was born 27th February 1792, the son of a cartwright at Granatula, in La Mancha. He was intended for the priesthood, but in 1808, on the invasion of Spain by the French, he volunteered into the *Batallion Sagrado* ('Sacred Battalion') of students, and after the close of the war of independence in 1814 went to South America, where he fought against the insurgents, until Bolivar's great victory at Ayacucho in 1824 put an end to the Spanish rule on the American continent. In 1833 he declared for the succession of the daughter of Ferdinand VII., became in 1836 general-in-chief of the army in the north, viceroy of Navarre, and captain-general of the Basque provinces. Next year he drove the Carlists from before Madrid across the Ebro, defeated their forces at Luchana and Burgos, and drove Don Carlos across the frontier into France. For his success Espartero was made Grandee of Spain and Duke of Vittoria. In 1840 the queen-mother Christina was compelled to resign her office of regent, and next year Espartero was appointed

by the Cortes to supply her place until the queen (Isabella) should have reached her majority. He guided the helm of the state through socialist and Carlist troubles with energy, firmness, and ability, until a combination of the Republicans and the Moderados brought about his fall in 1843. He resided for four years in England, then, returning to Spain, lived quietly at Logroño from 1847 till 1854, when they again called Espartero to the head of the government. For two years he conducted the affairs of the nation; but in 1856 was supplanted by O'Donnell, and in 1857 resigned his dignity as senator. After the revolution of 1868, which resulted in the expulsion of Queen Isabella, Espartero gave his full and hearty support to the provisional government, though he took no part in their proceedings. In 1870 his name was put forward for the throne of Spain; but he soon withdrew it, and in 1875 tendered his adhesion to Alfonso. He died at Logroño, 9th January 1879. There is an elaborate Life by Florez (Madrid, 1843-45).

**Esparto** (*Stipa tenacissima*), a grass nearly allied to the well-known and beautiful Feather-grass (q.v.), a native of the south of Europe (especially Spain, between Alicante and Malaga) and North Africa (between Oran and Tripoli). From very ancient times it was used on both sides of the Mediterranean for the making of carpets, sandals, ropes, baskets, nets, and sacks, and as a substitute for horse-hair; but its chief application is now as a material in paper-making (see PAPER), for which it is mostly exported to Britain, which from all parts receives about 150,000 tons of esparto annually. The grass grows wild, requires little rain, and is pulled once a year; but two crops are taken in some parts of Spain, where it has also been the practice to pluck, not cut, the plant. It covers large areas from the seashore up to a considerable altitude, and accustoms itself to the poorest rocky and sandy soils. Its reckless and excessive exploitation, with the resultant injury alike to the supply and to the soil itself, has recently led to official inquiry and governmental regulation in Algeria, as already in Spain, and has also induced the extension of our knowledge of the whole life-history and relations, biological and economic, of this important plant. See Trabut, *Étude sur l'Halfa* (Algiers, 1889).

The name esparto, the Spanish form of the Latin *Spartium*, as well as the Arabic name *halfa* now naturalised in French, is also applied, especially in Tunis and Tripoli, to another somewhat similar and related grass, *Lygium spartium*, more accurately known, however, in French as *Albardine* and in Arabic as *Sennoc*. A third grass, also of similar habit, uses, and distribution, is the Byss (*Ampelodesmos tenax*). In Egypt the name halfa is applied to *Eragrostis cynosuroides*, and in Fezzan to

Esparto Grass  
(*Stipa tenacissima*).

*Imperatu cylindrica*. Esparto is sometimes even confusedly applied to *Spartium junceum* and other leguminous plants. See BROOM.

**Espinasse.** See L'ESPINASSE.

**Espinel**, VINCENT DE, a Spanish poet and musician, was born at Ronda in Granada, 28th December 1551. He studied at Salamanca, and afterwards served as a soldier in Flanders, meeting with some of the adventures which he relates in his *Vida y Aventuras del Escudero Marcos de Obregon* (Madrid, 1618 and 1804; Eng. trans. by Langton, 1816), a book that was largely drawn upon by Lesage for his *Gil Blas*. Espinel afterwards returned to his native country, and took holy orders. Although holding the office of chaplain to the hospital at Ronda, he spent most of his time in Madrid, where he died in 1634. He was a friend of Lope de Vega. He also published a volume of poems (1591), chiefly lyrics, and a translation of the *Ars Poetica* of Horace. He was, if not the inventor, the improver of the ten-line octosyllabic stanza. Verses written in this form have, since his day, been called in Spain *espinelas*. Espinel was a performer on the guitar, to which he added the fifth string.

**Espirito Santo**, a small maritime province of Brazil, lying immediately to the north of the province of Rio Janeiro. Area, 17,053 sq. m.; pop. 100,717. The surface is mostly flat and swampy, the climate moist and hot, and the vegetation luxuriant. Sugar, coffee, cotton, and timber are exported, but the trade is not of much importance. The former capital, Espirito Santo, founded in 1535 on a bay of the same name, has sunk to a fishing-village; the present capital is Victoria, on the same bay.

**Espiritu Santo** (Span., 'Holy Spirit'), the largest and most westerly island of the New Hebrides, with an area of 1868 sq. m., and a pop. of 20,000. The soil is fertile, but the climate is unhealthy.—Espiritu Santo is also the name of an island in the Gulf of California, 30 miles N. of La Paz; of a cape of Tierra del Fuego, near the entrance to the Strait of Magellan; of the mountains separating Honduras and Guatemala; and of several other places in the old Spanish colonies.

**Espy**, JAMES POLLARD, meteorologist, born in Pennsylvania in 1785, practised law in Ohio, and was afterwards a classical teacher in the Franklin Institute of Pennsylvania. His theory of storms excited considerable attention at the time (see STORMS); and his work on the *Philosophy of Storms* (1841) was highly praised by the French Académie des Sciences. Appointed in 1843 to the Washington observatory, Espy there laid the basis of the Weather Bureau, which has since become an important branch of the War Department. He died 24th January 1860.

**Esquimalt**, a small port at the south end of Vancouver Island, on Juan de Fuca Strait. It is used as a British naval depot. Pop. 614.

**Esquimaux.** See ESKIMO.

**Esquire** (Old Fr. *esquier*, 'a shield-bearer'), originally the shield-bearer or armour-bearer of a knight. A knight fully equipped was in the days of chivalry attended by two esquires, whose spurs were of silver, not of gold, like the knight's. And when the sovereign created esquires, silver spurs were placed on their heels, and collars of SS round their necks. It is difficult to define exactly who in strict law is now entitled to the designation esquire. A Gentleman (q.v.) is one who bears coat-armour (*insignia gentilitica*), but not every gentleman is an esquire. Blackstone quotes with approval Camden's definition of four classes of esquires: (1) 'The eldest sons of knights, and their eldest sons in perpetual succession.' (2) The eldest sons of

younger sons of peers, and their eldest sons in like perpetual succession; both which species of esquires Sir Henry Spelman entitles *armigeri natalitii*. (3) Esquires created by the king's letters-patent or other investiture, and their eldest sons. (4) Esquires by virtue of their offices, as justices of the peace, and others who bear any office of trust under the crown.' 'To these,' continues Blackstone, 'may be added the esquires of Knights of the Bath, each of whom constitutes three at his installation, and all foreign, nay Irish peers.' The mention by Blackstone of Irish peers arises from the fact that peers of Ireland were before the Union legally foreigners. Camden's third class no longer exists, creation by letters-patent or investiture having long ago ceased. Christian, in his notes to Blackstone, would limit the holders of 'offices of trust under the crown' to those who are styled esquires by the king in their commissions, and he remarks the omission in Blackstone's enumeration of barristers, who have been decided by the Court of King's Bench to be esquires by office. No esquires to Knights of the Bath have been appointed since 1812, and by the statutes of 1847 these knights have no longer the power to nominate them. It is needless to add that in common usage the designation of esquire is loosely given in the present day, both in Britain with its colonies and in the United States, to all persons supposed to be in comfortable circumstances.

**Esquirol**, JEAN ÉTIENNE DOMINIQUE, one of the greatest physicians for the insane, was born at Toulouse, 4th January 1772. He served in the military lazaretto at Narbonne in 1794, and was appointed physician to the Salpêtrière at Paris in 1811. After 1817 he delivered clinical lectures on the diseases of the brain, and their cures; in 1818 his exertions secured the appointment of a commission, of which he became a member, for the remedy of abuses in mad-houses; in 1823 he became inspector-general of the University, and in 1825 first physician to the *Maison des Aliénés*, while managing his private asylum at Charenton. The July revolution deprived him of all his public offices, and he withdrew into private life. He died 12th December 1840. Esquirol's writings embrace all the questions connected with the treatment of insanity; his influence on the treatment of the insane has been very powerful for good, and most of the modern lunatic asylums in France have been built according to his advice. He published *Des Illusions chez les Aliénés* (1832) and *Des Maladies Mentales* (1838).

**Esquiros**, HENRI ALPHONSE, a French poet and politician, was born at Paris, 24th May 1814. At twenty he made his début with a volume of poems, which was followed by two romances, *Le Magicien* (1837) and *Charlotte Corday* (1840). His *Évangile du Peuple* (1840), a democratic commentary on the life of Jesus, cost him eight months' imprisonment and a fine of 500 francs, but gave him leisure and inspiration for his *Chants d'un Prisonnier*. His *Vierges Folles*, *Vierges Martyrs*, and *Vierges Sages* (1841-42) showed further his socialistic sympathies. After the revolution of February 1848, Esquiros was elected a member of the Legislative Assembly, but the *coup d'état* of 1851 drove him to England, where he gathered the materials for his *English at Home*, *Cornwall and its Coasts*, and *Religious Life in England*. Permitted by the amnesty of Napoleon III. to return to France, he was appointed supreme administrator of Bouches-du-Rhône by the government of the National Defence in 1870, next year was returned to the National Assembly, and in January 1875 was made a member of the senate, but died at Marseilles, 12th May 1876.

'**Essays and Reviews**,' the title of a remarkable volume published in 1860, containing the following seven papers: (1) 'The Education of the World,' by Dr Temple; (2) 'Bunsen's Biblical Researches,' by Dr Rowland Williams; (3) 'On the Study of the Evidences of Christianity,' by Professor Baden Powell; (4) 'The National Church,' by H. B. Wilson; (5) 'The Mosaic Cosmogony,' by C. W. Goodwin; (6) 'Tendencies of Religious Thought in England, 1688-1750,' by Mark Pattison; (7) 'The Interpretation of Scripture,' by Professor B. Jowett. All the writers, except Mr Goodwin, were clergymen of the Church of England, and their work, which was censured for its heterodox views by nearly all the bishops, and formally condemned by convocation in 1864, caused much excitement and controversy. Dr Williams and Mr Wilson were sentenced by the ecclesiastical courts to suspension for a year, but on appeal the sentence was reversed by the Privy-council; and Dr Temple's election to the see of Exeter in 1869 was also ineffectually opposed. The most important replies to the *Essays and Reviews* were those edited by Bishop Thomson (afterwards Archbishop of York) and by Bishop Wilberforce.

**Essek**, the capital of Slavonia, on the right bank of the Drave, 12 miles above its confluence with the Danube, and 189 S. of Pesth by rail. The Roman *Mursia*, and the seat of a bishopric since 335 A.D., it has a prosperous trade in corn, livestock, wood, &c. Pop. 18,201.

**Essen**, a town in Rhenish Prussia, 22 miles by rail N.E. of Düsseldorf, stands in the midst of a rich coal and iron district. It possesses numerous establishments for manufacturing iron, chief among them being the celebrated Krupp works and cannon-foundries, which employed 74 men in 1848, and 20,960 in 1888; in the same year there were in the Krupp works 1193 furnaces, 92 steam-hammers—some of great size—236 boilers, and 370 steam-engines, 2735 tons of coal and coke being used, and nearly 800 tons of iron produced in the works daily. Besides this great establishment, there are also manufactures of tobacco, walking-sticks, and vinegar, with dye-works and breweries. Pop. (1875) 54,852; (1885) 65,074. Although the industrial activity of Essen is recent, the town itself dates from the foundation of the Benedictine nunnery in 873. One of the churches of the place, also founded in the same year, presents several architectural features of interest.

**Essence** (Lat. *essentia*, from *esse*, 'to be'), as a philosophical term, the equivalent of the Greek *ousia*, was originally used in the same sense as *Substance* (q.v.). Later, substance came to be used for the undetermined substratum of a thing, essence for the qualities expressed in the definition of a thing; or, as Locke put it, 'Essence may be taken for the very being of a thing, whereby it is what it is.'—In Chemistry, and in popular parlance, essences are solutions of the essential oils in alcohol, and may be prepared (1) by adding rectified spirit to the odoriferous parts of plants, or to the essential oils, and distilling; or (2) simply by adding the essential oil to the rectified spirit, and agitating till a uniform mixture is obtained. Thus the essence of lemons is merely a solution of the volatile oil of lemons in rectified spirit. The term has, however, received a wider significance, and is applied to any liquid possessing the properties of the substance of which it professes to be the essence. Thus essences of coffee, beef, and rennet contain in a concentrated form the virtues of coffee, beef, and rennet, and in some circumstances may be substituted for them.

**Essenes** (*Essēnoi*, *Essaioi*), a small religious fraternity among the Jews, whose name and origin,

as well as character and history, are alike involved in obscurity. The Essenes bore one of the most momentous parts in the development of Judaism. Christianity stands in so close connection with them that John the Baptist and Christ himself have by some been pronounced to have issued from their ranks; and Islam still bears traces of an original connection. Josephus, Philo, Pliny, Eusebius, and the Fathers generally were long considered the sources, and the only sources, from which the genuine history of this fraternity could be deduced. Strange that for so many centuries the real and genuine sources—the Talmudical writings—should never have been thought of. These, together with Josephus and Philo, Pliny, Makrisi, and Alulfaraj, better enable us to form an idea of the real state of this community. Exception must be taken to the opening statement of Josephus, that there were three different 'sects' among the Jews—the Pharisees, the Sadducees, and the Essenes. The Sadducees were a political party, nothing more or less; and the Pharisees, forming as they did the bulk of the nation, cannot rightly be called a *sect*. Least of all were the Essenes such. They were Pharisees of stronger convictions, and carried out the Pharisaic views with a consistency which made them ridiculous even in the eyes of their own mother-party. The comparatively modern name of Essenes may be derived either from a Chaldee word *sacha*, meaning 'bathers' or 'baptists,' or from *asri*, meaning 'healers.' The Mishna, Beraitha, and Talmud speak of these advanced Pharisees in general as Chasidim (*Assiduiot*, 'pious men'), Nazirim ('abstinents'), and Toblé Shacharith ('hemerobaptists').

The Nazirim, a kind of voluntary priesthood, enjoining abstinence from wine, flesh, and other sensual enjoyments, had in the troublous times of anti-Syrian agitation, and the general upheaving of society, found numerous adherents; and gradually there sprang up a host of men calling themselves 'Nazirs for ever' (*Nazire olam*). Pharisees of a spiritual and contemplative bias took this vow of Nazirism for life, and constituted themselves into a sort of religious club. Levitical purity in its strictest and highest sense made them draw closer and closer the innumerable 'fences' which the traditional law had erected round the Biblical law. Thus it became necessary, or at least expedient, that those among them who could break all ties of friendship and family should retire into a solitude not easily approachable by a stranger to their community. Food, again, could not be prepared save by those of the brethren who knew and strictly obeyed the hyper-traditional injunctions. Their dress, every implement of daily use, had to be made under similarly stringent laws of purity. A natural consequence of this exalted notion of outward priesthood was their general celibacy. In this state of voluntary isolation, trading was out of the question: they tilled the ground, and lived on the fruits of the earth. Taking their meals, and these of the coarsest and plainest description, in common, they idealised the table into an altar, and, prayer having been said, they remained standing silently round it during the repast. That they had no individual property follows of course, and their communistic motto, which the Mishna (Aboth) has preserved to us—'Mine is thine, and thine is mine'—explains itself. We need not enlarge further on their small eccentricities—on the white linen garment, the apron, the scoop or shovel; they are one and all signs and symbols of Levitical purity. Every morning they bathed, like the priests who ministered in the temple, in pure spring-water. They abhorred blood as a source of impurity, and for this reason, probably, some of them abstained

also from going up to the temple, where sacrifices were daily offered; others we find present at a festival in the temple (Succah, 51, 53). But these were but outward signs of purity, stepping-stones to inner piety, to communion with God, which was only to be acquired, according to their notion, by solitude and an ascetic life. The belief in the efficacy of the most rigid simplicity and willing self-sacrifice they held in common with the Pharisees; their horror of oaths, their frequent prayers, their occupation with mystical doctrine were their own. Untroubled by the noise of war or the strife of parties, leading a life divided between ablutions, contemplation, and prayer, despising the body and bodily wants—what more natural than that by degrees they should be led into a kind of mystical enthusiasm and fanaticism? They allegorised, they symbolised; and their efforts culminated in seeing the unseen.

Angelology, derived from the Magi, formed a prominent feature of their creed. In course of time, they were looked upon by the vulgar as saints and workers of miracles: they cast out demons, and healed the sick. Jehovah is the original light; from him proceed a number of spirits, and at their head stands the Wisdom, or *Logos*, into which, after death, the soul is again absorbed. Their code of ethics was threefold—the love of God, of virtue, and of man, their scale of perfectibility reaching its acme in the communion with the Holy Spirit—*Ruach Hakodesh* (Mishn. Sota, 99). In fine, mixing up, in the strangest manner, the most exalted and the most puerile notions, they became the forerunners of the Christian Gnostics and of the Jewish Cabbalists. One fragment of their literature alone remains; it is quoted in the Talmud (Jerusalem. Berachoth) in the following words: 'It is written in the book of the *Chasidim*, If thou leavest it (the divine law) for one day, it will leave thee for two.'

They seem never to have numbered more than four thousand, including even those Nazirs or Essenes who remained in their own families. Their colony appears to have been established chiefly near the Dead Sea, and it is undoubtedly this colony which has served Josephus as a basis for his romantic Essene republic. But, however distant from each other they might be, a constant intercommunication was kept up through a body of delegates, or angels (Malachim). As they had sprung from the Pharisees, so they again merged into them; the remaining part became Therapeutæ, or Christians. The Talmud gives a distinct account of their ceasing to exist as a separate community (Bechorot, 27).

See the Talmud, the Midrash, Josephus, Philo; the histories of the Jews by Ewald and Grätz; Sprenger, *Leben Muhammads* (1861); Reuss, *La Théologie Chrétienne*; Keim, *Jesus of Nazara*; Lightfoot on the Colossians; Zeller, who, in his *Philosophie der Griechen*, makes them indirectly influenced by non-Jewish, neo-Pythagorean doctrines; Lucius, *Der Essenismus* (Strasburg, 1831).

#### Essential Oils. See OILS.

**Essequibo**, the most westerly of the great rivers of British Guiana, rises in the Aearai Mountains, 46 miles N. of the equator, and after a course of 620 miles enters the Atlantic, forming an estuary 15 miles wide, in which lie numerous fertile islands. The entrance to the river is rendered difficult owing to the sand and mud collected at its mouth; its course, which is through magnificent forest scenery, is much broken by cataracts, and it is navigable for 35 miles only. It receives a number of large tributaries, as the Rupununi, and the united Cuyuni and Mazaruni; on the Potaro, another affluent, is the grand Kaieteur Fall, 741 feet in sheer descent, discovered in 1870. The county of Essequibo, lying to the west of the river,

has a coast-line of about 120 miles, nearly to the mouth of the Orinoco.

**Essex**, a maritime county in the east of England, washed by the North Sea, and separated from Kent by the Thames estuary, from Suffolk by the Stour. Measuring 57 miles from east to west, and 44 from north to south, it has an area of 1657 sq. m. The low flat sea-board is close on 100 miles long, deeply indented by shallow creeks, and much of it fringed by the desolate salt-marshes described so well in Baring-Gould's *Mohalah*. Inland the surface becomes gently undulating or even hilly, the principal eminences being Danbury Hill (600 feet), Landon Hill (620), and High Beech (759). The rivers are the Thames, Stour, Lea, Stort, Colne, Blackwater, Crouch, Rodling, and Chelmer—rivers that sometimes flood the low-lying lands, as notably in the summer of 1888. Four years before, an earthquake, proceeding from north-east to south-west, did almost £10,000 damage. Chiefly occupied by the stiff London clay, but with chalk in the north-west, and crag near Harwich, Essex offers a great variety of soil. Nearly 79 per cent. of the entire area is in cultivation; and as Essex is more than most counties purely agricultural, so it has suffered more than most through the agricultural depression, 21,472 acres being thrown on the landlords' hands in 1887. Epping Forest (q.v.) is a mere remnant of the once wide woodlands, whose total area throughout the whole county is now reduced to less than 44 sq. m. Fishing is prosecuted, though not very actively; and the Colne has long been famous for its oysters. Brewing is an important industry, especially at Romford; but outside of the metropolitan area there are no great manufactures. Essex since 1877 has been included in the new diocese of St Albans, and since 1885 has returned one member to parliament for each of its eight divisions—South-west or Walthamstow, South or Romford, West or Epping, North or Saffron Walden, North-east or Harwich, East or Maldon, South-east, and Mid or Chelmsford. The County Council consists of eighty-four members. Chelmsford is the county town; and towns other than the above are Colchester, Stratford, Barking, Braintree, Brentwood, Coggeshall, Dunmow, Halstead, Harlow, Ilford, Ongar, Witham. Pop. (1801) 227,682; (1841) 344,979; (1881) 576,434; (1891) 785,399. Essex, named after the East Saxons, has little history apart from Colchester (q.v.); its only battlefield is Ashington (Assandun). The palaces of Havering and Theobalds are no more; but the Norman keep of Castle Hedingham still stands, and Andley End, a splendid Jacobean mansion. Old halls too are plentiful; and there are ruins of more than a dozen monastic houses. Of Essex worthies the chief have been Tusser, John Ray, Quarles, Sydney Smith, and Isaac Taylor. See the county histories of Morant (2 vols. 1768) and Snelling (1845); also E. Walford's *Guide to Essex* (1882).

**Essex**, EARL OF, a title conferred in 1572 on Walter Devereux (1541-76), scion of a very old Herefordshire house, the daring but luckless coloniser of Ulster. The title had been previously borne by the Mandevilles, the Bohuns, the Bourchiers (Devereux's ancestors), and by Thomas Cromwell (q.v.).

ROBERT DEVEREUX, Walter's eldest son and successor, was born at Netherwood, near Bromyard, on 10th November 1567, at nine was sent by Burghley, his guardian, to Trinity College, Cambridge, and at thirteen got his M.A. He had been taken to court the Christmas of 1577; in 1580 Leicester had become his step-father; and under Leicester he first saw service in the Netherlands (1585-86), for his valour at Zutphen being made a

knight-banneret. Back at court, the young gallant quickly won the 'singular countenance' of the elderly queen. In the words of his college-friend Bagot, 'when she is abroad, nobody near her but my L. of Essex; and at night my Lord is at cards or one game or another with her, that he cometh not to his own lodging till birds sing in the morning.' There were tiffs between them, over his bickerings with Raleigh, his duel with Blount, his stealing off to fight in Portugal, moneys lent by Elizabeth, his favouring of Puritanism, and, worst of all, his clandestine marriage in 1590 with Walsingham's daughter, Sir Philip Sidney's widow. Ere long, however, he was once more 'in very good favour,' and in 1591 commanded the forces despatched to help Henry IV. in Normandy against the League; in 1593 was sworn a privy-councillor; and by 1594, thanks to Bacon, who made him his stalking-horse, was acting as a sort of foreign secretary. His was the principal glory of the brilliant capture of Cadiz (1596); but his, too, largely the failure next year of the 'Islands Voyage' (see **RALEIGH**). In 1597 Essex became Earl Marshal, in 1598 Chancellor of Cambridge; but meanwhile occurred his great quarrel with Elizabeth, when he turned his back on her, exclaiming that her conditions were as crooked as her carcass. A box on the ear and 'Go and be hanged' was her answer; and, clapping hand to sword, Essex vowed he would never put up with so great an indignity. They never were properly reconciled. His six months' lord-lieutenancy of Ireland proved an utter fiasco; his army of sixteen thousand dwindled to barely four; and, concluding a truce with the arch-rebel Tyrone, he hurried back to England, and burst into Elizabeth's bedchamber. She received him not ungraciously at first; still, imprisonment followed, and deprivation of all his dignities. And now he formed the mad plot for removing Elizabeth's counsellors, in pursuance of which, on Sunday, 8th February 1601, he attempted vainly to raise the city of London. On the 19th he was found guilty of high-treason, on the 25th beleagued in the Tower. Elizabeth signed his death-warrant reluctantly; but the story of the ring, given him by the queen for a safeguard, but kept back by the Countess of Nottingham, is an invention of fifty years afterwards. A patron of letters, Essex was himself a sonneteer; and Cooper's *Athena Cantabrigienses* (1861) gives a longish list of his writings. See the authorities cited there and in our articles **BAUCON** and **ELIZABETH**.

**ROBERT DEVEREUX**, eldest son of the preceding, was born in January 1591, and in 1604, soon after James I.'s accession, was restored in blood as third Earl of Essex. When just fifteen, he was married to a daughter of the Earl of Suffolk, but during his two years' travels on the Continent (1607-9) she and Carr fell in love with each other, and Carr, on getting a divorce, she married (1613). Essex's own second marriage (1631) was almost as unhappy as the first. From 1626 he had attached himself to the popular party, and the Long Parliament brought him to the front; in July 1642, withstanding all Charles's blandishments, he received the command of the parliamentary army. A dull, worthy soul, a striking contrast to his brilliant sire, he was brave enough personally, but a very poor general; and to his hesitancy and inactivity the prolongation of the war was largely due. The drawn battle of Edgehill, the capture of Reading, and the relief of Gloucester were followed by his blundering march into Cornwall, whence he himself fled by sea. On 2d April 1646 he resigned the command, and on 14th September he died. The title died with him; but in 1661 it was revived in favour of Arthur, second Lord Capell (1635-83), the ancestor of the present earl. See works cited at **CHARLES I.**, and

Walter Bouchier Devereux's *Lives of the Devereux, Earls of Essex* (2 vols. 1853).

**Esslingen**, a manufacturing town of Würtemberg, on the Neckar, in the centre of a pleasing and fertile district, 9 miles by rail ESE. of Stuttgart. It consists of the inner town, which retains much of its old walls and towers, and of several suburbs, embosomed in gardens and vineyards. The chief buildings are the old citadel, the Liebfrauen Church (1440)—a splendid Gothic edifice, with a beautiful spire 246 feet high—the old (1430) town-honse, and the new (1742). It has the greatest machine-shops in the kingdom, a lithographic establishment, and manufactures of a wine called Esslingen champagne, of woollens, of cotton and woollen yarns, lackered iron, silver-plate, and tin wares, with a good trade in wine and fruit. Pop. (1875) 19,602; (1885) 20,851. Esslingen was founded in the 8th century, and received in 1209 the rights of a free city of the Gennan empire. During the 15th century it was engaged in a bitter contest with the counts and dukes of Würtemberg. In 1802 the town, with its territory, was assigned to the duchy of Würtemberg.

**Essonan**. See **ASSOUAN**.

**Established Church**. See **ENGLAND (CHURCH OF)**; **SCOTLAND (CHURCH OF)**; and for the question of the duty of the state towards religion, **STATE CHURCH**, **VOLUNTARIYISM**.

**Estaing**, **CHARLES HECTOR THÉODAT, COMTE D'**, naval officer, was born in Auvergne in 1729, became brigadier in 1756, and afterwards served in the East Indies with Lally. In 1778, as vice-admiral, he sailed with sixteen vessels to co-operate with the colonists against the British. He captured St Vincent and Grenada in 1779, but his efforts on the mainland were uniformly unfortunate; and in 1780 he returned, severely wounded, to France, where he persuaded the ministry to send 6000 men to the colonists' aid. His loyalty to the royal family, and especially to the queen, outweighed his services to his country, and he was guillotined in Paris, 28th April 1794.

**Estate**, in the law of England, is the state or legal relation in which a person stands to his property, or, in other words, the quantity of interest he has in it. The first division of estates is into legal and equitable. By the former is signified the estate which a man has by the common law; by the latter, the interest which has been created by the operation of a court of equity (see **EQUITY**, **USES**, **TRUST**). Estates in land may be considered with reference to the quantity of the estate, the time of enjoyment, and the number of persons who may unite in the enjoyment. Under the first head, estates are either freehold or less than freehold. Freehold estates, again, are divided into freeholds of inheritance, or Fees (q.v.), and freeholds not of inheritance, or for life. An estate for life may be for the life of the person to whom it is granted, or for that of another person, or for more than one life. A person holding an estate for the life of another is called tenant *pur autre vie*. An estate *pur autre vie* granted to a man and his heirs descends, in case of the death of the tenant intestate, during the life for which he holds to his heir. An estate by the courtesy of England, and an estate in dower, are estates for life. A conveyance by deed to A. B., without words giving him an estate of inheritance, makes the grantee tenant for life. An estate to a woman during her widowhood, or to a man until the occurrence of a specified event, as till he receive a benefice, will be construed to be an estate for life, but the estate is determinable on the event happening. Tenants for life are entitled to take Estovers (q.v.), but

they must not commit Waste (q.v.). The representatives of a tenant for life are also usually entitled to take the emblements on the expiry of the term. Estates less than freehold are called also chattels real. This species of estate, on the death of the tenant, passes, like other Chattels (q.v.), to the executor, and not to the heir. They are divided into estates for years, estates at will, and estates on sufferance (see LEASES). Estates, with reference to the time of their enjoyment, may be either in possession or in expectancy. An estate in possession comprehends not only an estate in the actual occupation of the tenant, but one from which he has been wrongfully ousted. In this latter case the law regards the rightful tenant as having the actual estate, to which is attached the right of entry. An estate in expectancy may be either in Reversion (q.v.) or Remainder (q.v.). Estates of this character form a large portion of the rights to land in England, and are the subject of some of the most subtle learning of the English law. With reference to the number of persons entitled to the enjoyment, estates may be in severalty, in joint-tenancy, in co-parcenary, or in common. An estate in severalty is where the sole right to the estate is in a single person. See CO-PARCENARY, LAND-LAWS, REAL, TENANCY IN COMMON.

**Estates of the Realm.** The three estates of the realm are not King, Lords, and Commons, as is popularly believed, but the Lords, the Clergy or Spirituality, and the Commons, which estates, together with the king or queen, form the parliament of the United Kingdom of Great Britain and Ireland. (For an apology for the common error, see Lister's *Life of Clarendon*, vol. i. p. 190-196; see also the article PARLIAMENT.) The ancient parliament of Scotland consisted of the king and the three estates of the kingdom, by which latter was meant—(1) the archbishops, bishops, abbots, and mitred priors; (2) the barons, under which head were comprehended not only the nobility, but the commissioners of shires and stewartries; and (3) the commissioners from the royal burghs. In Sir David Lindsay's *Satire of the Thrie Estaitis*, it is before Spirituality, Temporality (landholders), and Burghesses that John the Common Weill makes his complaint. The expression *Fourth Estate* for the newspapers is ascribed by Carlyle to Edmund Burke, who said that in the reporters' gallery there was a fourth estate more powerful than any of the other three. In France the nobles, the clergy, and the third estate (*tiers état*) remained separate down to 1789 (see FRANCE); in England the greater clergy became Lords Spiritual, the lesser clergy became, for political purposes, part of the Commons, and parliament was organised in two houses. In Sweden there were, till 1866, four estates or houses—nobles, clergy, citizens, and peasants.

**Estate Tail.** See ENTAIL.

**Este** (ancient *Ateste*), a town of Italy, on the southern slope of the Euganean Hills, 17 miles SSW. of Padua. It is an old place, with a decidedly Lombard appearance, many of the houses being supported by arches. Its most interesting buildings are the *Rocca*, or castle, overhanging the town, and a Romanesque church, surmounted by a leaning campanile. Este has some manufactures of porcelain and finience wares. Pop. 5979.

**Este**, one of the oldest and most illustrious families of Italy, possibly of Langobard origin, whose heads from an early date ranked as keepers of the marches of upper Italy, and afterwards received from the emperors several districts and counties, to be held as fiefs of the empire. In 1097 the family divided into two branches, the German and Italian. The former was founded by Welf IV., who had

received the investiture of the duchy of Bavaria from the Emperor Henry IV. in 1070. From him are descended the Houses of Brunswick and Hanover, and consequently the sovereigns of Great Britain, also called Este-Guelphs (see GUELPHS). The Italian branch was founded by Welf's brother, Fulco I.; and for several centuries the history of the Este family as heads of the Guelph party is interwoven with the destinies of the other ruling families and small republics of Northern Italy. During this period they first gained possession of Ferrara and the march of Ancona, and afterwards of Modena and Reggio, and were widely celebrated as the patrons of art and literature. Among the most illustrious members of the family was Alfonso I. (died 1535), equally distinguished as a soldier and a statesman, and celebrated by all the poets of his time, particularly by Ariosto. His second wife was the notorious Lucrezia Borgia. A quarrel with the Popes Julius II. and Leo X. brought about the forfeiture of his papal fiefs, which were restored by Charles V. after the siege of Rome in 1527. His successor, Ercole II., who married Renate, daughter of Louis XII. of France and Anne of Brittany, attached himself to Charles V. His brother, a dignitary of the Catholic Church, erected the magnificent Villa d'Este at Tivoli. The next prince, Alfonso II. (died 1597), would have been no ways inferior to the preceding but for his immoderate love of splendour, his inordinate ambi-

Italian houses, separated since 1070. The male line of the House of Este became extinct on the death of Ercole III. in 1803, whose only daughter married the Archduke Ferdinand, third son of Francis I. of Austria. Their eldest son, Francis IV., by the treaty of 1814-15, was restored to the duchy of Modena, and on his mother's death obtained the duchies of Massa and Carrara. He was succeeded in 1846 by his son, Francis V., who in 1859 was obliged to resign his territories to Victor Emmanuel. With the death of Francis V. in 1871 the Austrian branch also became extinct.

**Estella**, an ancient city of Spain, in the province of Navarre, on the Egra, 27 miles SW. of Pamplona. Pop. 6749. Here Don Carlos was proclaimed king in 1833; and Estella was again the Carlist headquarters from 1871 to 1876.

**Estepa**, a town of Spain, 60 miles ESE. of Seville. Pop. 8190.

**Estepona**, a maritime town of Spain, 26 miles NNE. of Gibraltar. It supplies Gibraltar with fruits and vegetables. Pop. 9994.

**Esterházy de Galantha**, one of the most powerful families of Hungary, raised in the 17th century to the rank of princes of the empire, the representative of which is at present one of the greatest landed proprietors in Austria. The family divided into three main branches—the Csesznek, Altsóhl or Zolyom, and Fraknó or Forchtenstein lines. Count Paul Esterházy of Fraknó (1635-1713) served in the Austrian army with such distinction as to gain a field-marshal's baton at the age of thirty, and for his successes against the Turks, and still more for his support of the House of Hapsburg, was made a prince of the empire in 1687. A descendant, Prince Nicholas IV. (1765-1833), founded the splendid collection of pictures at Vienna, and by this and other expenses brought his vast estates into sequestration. When Napoleon, in 1809, entertained the notion of weakening Austria by the separation of Hungary, he made overtures to Prince Esterházy respecting the crown of Hungary, which, however, were declined. His son, Prince

Paul Anton (1786-1866), entered at an early age on a diplomatic career, and represented the Austrian government at London until 1842. In 1848 he was for some time Minister of Foreign Affairs under Batthyányi. He added greatly, by his profusion, to the burdens imposed on the family property. The Esterházy estates include 29 lordships, with 21 castles, 60 market-towns, and 414 villages in Hungary, besides lordships in Lower Austria, and a county in Bavaria; but until its liabilities have been met, the family receives from its vast possessions only a limited yearly rental.

**Esther.** THE BOOK OF, relates how a Jewish virgin Hadassah (Heb. 'myrtle'), or Esther (Pers. 'star'), who was a foster-daughter of Mordecai, was chosen by the Persian king Ahasuerus (Xerxes) as his wife in room of the disgraced queen Vashti, and brought about the great deliverance of her people which is commemorated in the Feast of Purim ('lots'). Haman, the king's prime-minister, had issued a decree for the extirpation of all the Jews, and had prepared to hang Mordecai; but Mordecai, who had formerly detected a conspiracy against the king's life, was raised to great honour, and Haman was hanged on the gallows 50 cubits high that he had prepared for Mordecai. After this Esther, at Mordecai's instance, revealed her Hebrew lineage, and prevailed upon the king to counteract the former edict by another permitting the Jews everywhere to destroy their enemies. The Book of Esther stands alone among the Hebrew Scriptures as an expression of the uncompromising spirit of Hebrew nationality, containing hardly a trace of religious feeling. The name of God is not once mentioned, while the great king of Persia is referred to nearly 200 times. A possible explanation is the fact that the book was meant to be read at the merry revels of the Purim festival. It has continued in constant use and favour among the Jews, and of the five Hagiographical rolls it is called emphatically 'The Roll' (*Megillah*). The author is quite unknown, and the date is probably the latest Persian or the earliest Greek period. It has been much disputed whether the Book of Esther contains authentic history, or only 'the Legend of the Feast of Purim' (Reuss). It was discredited by such early Christian writers as Melito of Sardis in the 2d century, and Athanasius, Gregory of Nazianzus, and Amphilochius of Iconium in the 4th century. Luther, in his *De Servo Arbitrio*, says: 'Though they have this book in the canon, in my judgment it deserves more than all to be excluded from the canon;' and in his *Table-talk* he says: 'I am so hostile to the book that I would it were not in existence, for it Judaizes too much, and hath a great deal of heathenish naughtiness.' There are two Greek versions of the Book of Esther, containing a multitude of interpolations and additions, the earlier of which, it is clear, was known to Josephus. They are printed together in Usher's *De Græca LXX. Interpretum versione* (Lond. 1655), and in O. F. Fritzsche's *Libri Estheræ græci textus duplex* (Zurich, 1848), and *Libri Apocryphi Veteris Testamenti græci* (1871). In Jerome's translation all the Greek additions are placed at the end, and marked with an *obelus*. Hence in our Bibles they do not appear, being relegated to the Apocrypha. The story of Esther afforded a subject for the genius of Handel and of Racine.

See Zuntz, *Die Gottesdienstliche Vorträge der Juden* (1832); Fritzsche, *Exegetisches Handbuch zu den Apokryphen* (1851); Oppert, *Commentaire du Livre d'Esther* (1864); Langen, *Die deuterokanonischen Stücke des Buches Esther* (1862); and the commentaries by Bertheau (1862), Keil (1878), F. W. Schultz (1876), and Cassel (1878 *et seq.*). See ARABIAN NIGHTS; and the too ingenious *Helienistische Bestandteile im biblischen Schriftum* (Vienna, 1887), by J. S. Bloch.

**Esthonia**, called by the natives Wiroma, the most northerly of the Baltic provinces of Russia, is bounded E. by the river Narova, S. by Livonia, W. and N. by the Baltic, with an area of 7818 sq. m. It constitutes a broad flat ridge extending from west to east, with a very gentle slope towards Livonia, but a terrace-like steeper declivity next the Gulf of Finland. A large part of the surface is covered with forests, moors, and small lakes; rivers are numerous, but mostly small and sluggish in flow; erratic boulders of granite are common everywhere. The climate is changeable, and often very hot in summer and very cold in winter. Agriculture is the chief occupation of the people, the principal crops being rye, oats, barley, and potatoes. The coastal waters are rich in fish, especially anchovies. A large quantity of brandy is made, and some cotton spun and wool woven. The chief town is Revel (q.v.), the principal port. The population (387,085 in 1885) consists of two divisions, the Esths and the Esthlanders. The latter are a mixed race of immigrants, the German element strongly preponderating. German, which was until quite recently the official language and the language of the educated classes, is now being superseded by Russian, the use of the latter tongue having been made compulsory in all places of instruction by a decree of May 1887. The Esths, a people of Finnish race, constitute the peasantry, some 290,000 in number, and the original possessors of the soil. About 440,000 of this people are also found in Livonia, and 11,500 more in the governments of St Petersburg, Pskov, and Vitebsk. In spite of six centuries of slavery to their German lords, the Esths have preserved their national characteristics almost unaltered—language, customs, clothing, dwelling, physical attributes. There are two principal dialects, Dorpat and Revel Esthonian, which differ considerably. The people have a well-supported newspaper press, and excellent national songs, closely resembling those of the *Kalevala*. See Neuss, *Esthnische Volkslieder* (Revel, 1850-52, and St Petersburg, 1854); *Kalevi Poeg*, edited by Kreutzwald (Dorpat, 1857); and Jannsen's *Esthnische Mæren* (1881-88). In religion they are mostly Lutherans, though the Russians are making strenuous efforts to bring them over to the Greek Church; superstitious beliefs are widely prevalent. Esthonia was conquered by Waldemar II. of Denmark in 1219; but in 1346 it was sold to the Teutonic Knights, and incorporated with Livonia. From 1561 it belonged to Sweden, until in 1710 it was seized by Peter the Great, who definitively united it to his own dominions by the treaty of Nystad in 1721. Serfdom was abolished in Livonia in 1816, and in Esthonia in 1819.

**Estienne.** See STEPHENS.

**Estoile**, or STAR, in Heraldry, is distinguished from the Mullet (q.v.) by having six waved points, while the latter consists of five plain points.

**Estoppel**, a conclusive admission, which cannot be denied or controverted by the party whom it affects. Coke says that it is so called 'because a man's own act or acceptance stoppeth or closeth up his mouth to allege or plead the truth.' Estoppels are usually divided into three kinds—(1) By matter of record, where any judgment has been given in a court of record, the parties to the suit are estopped from afterwards alleging such matters as would be contradictory to the record. Where the judgment is wrongfully signed, the remedy is to apply to the court to set it aside. (2) By matter in writing. Thus, a party who has executed a deed will be precluded from afterwards denying, in any action brought upon that instrument, the fact of which it is evidence. (3) By matter in *pays*, as by acceptance of an estate, where e.g. a tenant cannot

dispute his landlord's title, or, a licensee of a patent is estopped from denying the patentee's right to the patent. Besides these, some other modern rules are referred to the doctrine of estoppel. Where a man's misrepresentation or negligence induces in another a belief in the existence of a certain state of facts, and action is taken upon that belief, the person guilty of misrepresentation or negligence is estopped or barred from denying the existence of that state of facts. Thus, the acceptor of a bill of exchange is barred from denying the handwriting of the drawer; and, where a person draws a cheque in so careless a way that the amount may be easily changed, he is estopped by his own negligence from suing his banker for paying any so increased amount. There is, further, equitable estoppel, or estoppel by acquiescence, where a person, by tacitly representing his own position to be more favourable to another than it is, has induced that other to act on the belief that the representation is true. The doctrine of estoppel prevails in America as well as in England. In Scotland, also, the same principle is recognised, under the name of Personal Exception (q.v.). See Michael Cababé, *The Principles of Estoppel* (1893).

**Estover**, the right which a tenant has to take a reasonable portion of the wood on an estate for certain definite purposes. Estovers, or *botes* (Saxon), are of three kinds—housebote, which is twofold—viz. *estoverium edificandi et arandi*, a right to wood for fuel and repairs of the house; ploughbote, *estoverium arandi*, wood for repairing instruments of husbandry; and haybote, *estoverium claudendi*, wood for repairing hedges and fences.

**Estrays**. See POUND.

**Estreat** (Lat. *extractum*), in English law, a true extract copy or note of some original writing or record, and specially of fines or amercements, as entered in the rolls of a court, to be levied by bailiffs or other officers. When, however, it is applied to a Recognisance (q.v.), it signifies that the recognisance itself is estreated for execution. If the condition of a recognisance be broken, the recognisance is forfeited; and on its being estreated the parties become debtors to the crown for the sums in which they are bound.

**Estrées**, GABRIELLE D', mistress of Henry IV. of France, was born about 1571. She had already parted with her virtue before she became acquainted with Henry, in 1590. For the sake of appearances, she was married to a gentleman of Picardy, named Liancourt, from whom, however, she soon separated. The king was so fond of her that, in spite of the opposition of Sully, he was about to divorce his consort, Marguerite de Valois, in order to marry Mme. de Liancourt, when the latter died suddenly at Paris on 10th April 1599.

**Estremadura**, a district of Spain, lying between Portugal and New Castile, and watered by the Tagus and the Guadiana. It is bounded on the N. by Leon, on the S. by Andalusia, and since 1833 has been divided into the two provinces of Badajoz (q.v.) and Cáceres (q.v.). Area, 16,701 sq. m.; pop. (1886) 799,639. Like the New Castilians, the inhabitants present a mixture of Mozarabic and Spanish blood, but are still graver and more taciturn than the former. The lower classes are rough and uncivilised, but honest and hospitable, modest, good-tempered, and brave.

**Estremadura**, a coast-province of Portugal, south of Beira, with an area of 6850 sq. m., divided into nearly equal portions by the river Tagus. The northern section is mountainous, with bare but picturesque continuations of the Castilian ranges; south of the river and along parts of the coast the country is hilly and better wooded. Many dis-

tricts are extremely fertile, others utterly barren; scarcely half the province is under cultivation, but in the most favoured localities all the vegetation of middle and southern Europe flourishes. The silk-culture has greatly increased of late years; manufactures are confined to Lisbon, and this city, with Setubal, monopolises also nearly all the trade. Sea-salt, soda, and fruits are the chief exports. The other principal products of the country are wine, oil, corn, and cork; but even the sandy plains are covered with cistus, rosemary, myrtles, and other flowering and fragrant plants. Pop. (1881) 946,472, over a fourth of the whole belonging to Lisbon and its suburbs.

**Estremoz**, a town of Portugal in the province of Alentejo, 23 miles N.E. of Évora. It is built round the base of a hill which is crowned by a once formidable castle, erected in 1360. Estremoz is famous for its jars of red porous earthenware for keeping water cool. Pop. 7575.

**Eszek**. See ESSEK.

**Étampes**, a town in the French department of Seine-et-Oise, 35 miles S.W. of Paris by rail. An ancient place, with a street 4 miles long, it has a fragment of a royal castle, the 'Tour de Guinette' (circa 1160), three interesting churches, a statue of the naturalist Geoffroy Saint-Hilaire, a medieval hôtel-de-ville, large flour-mills, market-gardens, &c. Pop. 8197.

**Étang** (Lat. *stagnum*) is the name given (*Étangs salés*) to large lagoons along the French coast, frequently salt, and generally communicating with the sea by channels. See BERGE.

**Etawah**, a town of the Doab, picturesquely situated among the ravines near the left bank of the Jumna, about 70 miles S.E. of Agra, is on the East Indian Railway, and at the junction of the Agra-Mainpuri and Gwalior-Farrukhabad roads. Half-hidden among trees, the town contains some handsome streets, and carries on a considerable trade. A native cloth, hair combs, and sweetmeats are manufactured. Close by are some famous Hindu places of worship, and the *ghats*, or lights of stairs leading to the river for the purpose of ritual ablution, are lined with handsome shrines. Pop. (1881) 34,721.—The district of Etawah, lying entirely in the basin of the Jumna, and almost exclusively within the Doab, has an area of 1693 sq. m., and a pop. (1881) of 722,371, nearly all Hindus.

**Etching**. See ENGRAVING.

**Etchmiadzin**. See ARMENIA.

**Eternal Punishment**. See HELL, CONDITIONAL IMMORTALITY, UNIVERSALISM.

**Ethelbert**, king of Kent, and third in direct descent from Hengist, was born in 552, and succeeded to the throne about the ninth year of his age. In a contest with Cenwlin, king of Wessex, for the title of Bretwalda, in 568, he was defeated at Wiltandune, now Wimbledon, in Surrey. About the year 590, however, he was acknowledged as Bretwalda of the Saxon octarchy. The most important events of his reign were his own conversion to Christianity, and the formal introduction of that religion into his kingdom, by St Augustine in 597. Ethelbert was also the author of the first written Saxon laws, the collection called *Dooms*, by Bede, 'which he established with the consent of his Witan in the days of St Augustine.' Ethelbert died in 616.

**Etheldreda**, St., a daughter of the king of East Anglia, was born about 630, and was twice married, her second husband being Oswy, king of Northumbria. To escape, however, from the married state, she withdrew first to the monastery founded by her aunt, Ebba, on St Abb's Head, and then to the Isle

of Ely (q.v.), where, in 673, she herself founded a monastic house. She died on 23d June 679, and was canonised, her festival falling on 17th October, the day of the translation of her body to its shrine in 695. Her name was popularly abbreviated or corrupted into St Andrey; and at a fair in the Isle of Ely, a common kind of lace was sold, which came to be known as St Andrey's lace. Hence *tawdry*, applied to any kind of frippery.

**Ethelred I.**, elder brother and predecessor of Alfred the Great, was king of Wessex and Kent from 866 till his death on 23d April 871, shortly after his great victory over the Danes at Æscedune or Ashdown, a victory supposed to be commemorated by the White Horse (q.v.).—**ETHELRED II.**, the 'Unready,' was only seven at the death of his father, King Edgar, and ten when in 978 the murder of his half-brother, Edward the Martyr, placed him on the English throne, and brought about Dunstan's fall. From boyhood he was swayed by unworthy and traitorous favourites, and his reign, 'the worst,' says Freeman, 'and most shameful in our annals,' was a series of raids and invasions by the Northmen, and endeavours to buy them off with ever-increasing bribes. Still, 'Unready,' his nickname, stands for 'redeless,' deficient in counsel; of misplaced energy he had more than enough. This showed itself in his treacherous massacre of the Danish settlers on St Brice's Day (13th November), 1002, a crime that was punished by fierce invasions, until in 1014 he was forced to take refuge in Normandy. In 1002 he had married Duke Richard's daughter, Emma; the marriage was fraught with important consequences, as the earliest link between England and Normandy. Sveyn's death soon allowed his recall, but on 23d April 1016 he himself died in London. He was succeeded by Edmund Ironside, third of seven sons by a first marriage; by Emma he was the father of Edward the Confessor.

**Ether**, or **ÆTHER**. Many physical phenomena are supposed to be due to the propagation of a state of stress or motion through a medium filling all space. Such a medium is called an ether. The theory of propagation through an ether is the exact opposite of the theory of direct action at a distance. Newton said that it was inconceivable to him that any one who was capable of thinking correctly in such matters could admit that direct action at a distance was possible. He suggested that Gravitation (q.v.) might be due to diminution of pressure in a fluid filling space in the neighbourhood of material bodies. Sir W. Thomson has shown that this diminution of pressure would be accounted for if we suppose that each particle of matter is a source at which an incompressible fluid is being constantly created at a rate proportional to the mass of the particle, the fluid being also constantly annihilated at an infinite distance. Or, conversely, we might suppose that the fluid is created at infinity, and absorbed and annihilated at each particle, at a rate proportional to its mass. In either case the motion of the fluid would be greatest in the neighbourhood of material bodies; but it is a known fact in hydrodynamics that, in a fluid, the pressure is least where the speed of motion is greatest. Thus the state of stress assumed by Newton would be accounted for.

Light and the so-called radiant heat are supposed to consist in waves of transverse vibrations which are propagated through the ether. Indeed, the phenomena of interference (see LIGHT) cannot be explained in any other way. Similarly, electric and magnetic effects are supposed to be due to the propagation of some state of stress through an ether. But it would be utterly unscientific to fill space over and over again with a new

medium for every special phenomenon which has to be explained in this way, and it seems probable that one medium can explain all. Maxwell has assumed the existence of, and has investigated the state of stress in, a medium through which electro-magnetic action is propagated. The equations which he obtains are identical in form with the equations of motion of an elastic solid, and the rate of propagation of an undulation is, in his theory, numerically equal to the ratio of the electro-magnetic and electrostatic units. This ratio is found by experiment to be numerically equal to the speed of propagation of light. Thus the medium which Maxwell assumed in order to explain electro-dynamic phenomena is identical, in his electro-magnetic theory of light, with the luminiferous medium; and the theory gives an explanation of reflection, refraction (single and double), and various other phenomena. Additional support has lately been given to the theory by the experiments of Hertz and others, which prove the existence of these electro-magnetic undulations, and show that they have properties identical with those of light. See ELECTRICITY, and LIGHT.

The ether seems to be of the nature of an elastic solid; and, in order to account for the immense rapidity of its vibrations when radiation passes through it, its rigidity must be excessively large compared with its density. It may be asked how, if this be so, the earth can move through the ether at the rate of nearly a million miles per day. But, if we consider that shoemaker's wax is so brittle a solid that it splinters under the blow of a hammer, and that it yet flows slowly like a liquid into the crevices of a vessel in which it is placed, and that bullets sink slowly down through it, and corks float slowly up through it, the motion of the earth through the ether does not seem so incomprehensible. The bullet moving through the wax experiences great resistance to its motion when it has to move, say, an inch in some weeks; but if we give it some years to move an inch, the resistance would be very small. So it may be that the motion of planets through the ether is relatively much the same as that of the bullet moving with excessive slowness through the wax. From magneto-optic phenomena it seems certain that something of the nature of molecular rotation is going on in the ether (see MATTER, and VORTEX).

There is no evidence of the existence of a condensational-rarefactional wave (as in the case of sound in air) in the ether. In the electro-magnetic theory it is got rid of from its velocity being infinite. In a theory of the ether recently advanced by Thomson, in which it is supposed to have negative compressibility, and to be made stable by being infinite or having rigid boundaries, the speed of propagation of the condensational-rarefactional wave is zero. The question of a contractile ether had been previously considered by Green, but was dismissed by him with the statement (erroneous, as Thomson has shown) that it is essentially unstable. The theories of an ether of zero or positive compressibility lead to results which are inconsistent with experiment. On the other hand, Thomson's theory leads to the known experimental results, as also does the electro-magnetic theory.

**Ether**, ( $\text{C}_2\text{H}_5\text{O}$ ), otherwise called **ETHYLIC ETHER**, **VINIC ETHER**, and **SULPHURIC ETHER**, is prepared from alcohol by the action of sulphuric acid at an elevated temperature. Alcohol is placed in a retort or still, and about an equal volume of sulphuric acid is added. Heat is at once developed by the mixing of the liquids, and on raising the temperature ether vapour passes over along with a proportion of alcohol. At the same time a stream of alcohol is allowed to pass into the still, and the heat is so regulated that a constant

temperature of about  $266^{\circ}$  ( $130^{\circ}$  C.) is maintained. When five volumes of alcohol in all have been added, the temperature is allowed to rise to  $286^{\circ}$  ( $141^{\circ}$  C.), at which point impurities commence to pass over. The ether so obtained contains alcohol, sulphurous acid, and water, and these may be removed by treatment with solution of chloride of calcium, &c., and subsequent redistillation.

The chemical reactions which take place in this process are of great interest, and may be divided into two stages. (1) The sulphuric acid acts on alcohol, forming ethyl-sulphuric acid and water.

Sulphuric Acid. Alcohol. Ethyl-sulphuric Acid. Water.

(2) This acid again is acted on by alcohol, with the re-formation of sulphuric acid and the production of ether.

Ethyl-sulphuric Acid. Alcohol. Ether. Sulphuric Acid.

From this it will be plain that the sulphuric acid is restored again, and is ready to attack alcohol anew, so as to form more ether. This process would go on indefinitely, were it not that the water liberated in the first reaction dilutes the sulphuric acid, and ultimately renders it too weak for further action.

Ether is a colourless, transparent, volatile liquid of great mobility and high refractive power, and possessing a fragrant odour and a fiery, passing to a cooling, taste. It has a specific gravity of  $\cdot 720$  at  $60^{\circ}$  ( $15.5^{\circ}$  C.), and boils at  $96^{\circ}$  ( $35.6^{\circ}$  C.), forming a vapour more than two and a half times as dense as air. When reduced to a temperature of  $-24^{\circ}$  ( $-31^{\circ}$  C.), ether freezes. It volatilises spontaneously when placed in an unconfined position, as in the palm of the hand, and vaporises so quickly as to produce intense cold. Indeed, when water is covered with ether, and the latter assisted in its evaporation by being blown upon, it escapes so readily as to reduce the temperature of the water to the freezing-point. It is very inflammable, burning with a yellow-white flame; and mixed with air or oxygen, it gives rise to a dangerous explosive mixture, and hence great care requires to be taken in its distillation to keep all lights and fires out of the room where the vapours are condensing. When ether is added to its own bulk of water, briskly agitated, and allowed to settle, the two liquids appear to separate again; but it is found that the ether has taken up one-eighth of its volume of the water, whilst the latter has dissolved the same quantity of ether. It is readily miscible with alcohol in all proportions. Ether is one of the best solvents for the oils and fats, and hence is employed in analysis for the solution and separation of the oils from other organic matters, as in the analysis of oil-cakes, &c. It is also a good solvent of iodine, sulphur, phosphorus, and of strychnine and other alkaloids, as well as of corrosive sublimate and other salts.

Ether enters into combination with many acids, forming compound ethers possessing great fragrance, such as

Acetic Ether. ....	$\text{C}_2\text{H}_5\text{C}_2\text{H}_3\text{O}_2$	
Butyric Ether. ....	$\text{C}_2\text{H}_5\text{C}_4\text{H}_7\text{O}_2$	Pine-apple Oil.
Valerianic Ether. ....	$\text{C}_2\text{H}_5\text{C}_5\text{H}_9\text{O}_2$	Essence of Quinces.

Cinnathic ether, on which the flavour and smell of wines, brandy, &c. so much depend, originally supposed to be a distinct ether, has been proved to be a mixture of various ethyl ethers, chiefly ethyl caprate.

Ether is useful in the preparation of freezing mixtures, the mixture of ether and solid carbonic acid giving rise to a very low temperature indeed. When inhaled by man and the lower animals, ether first produces stimulating and intoxicating effects, but afterwards it gives rise to drowsiness, accom-

panied by complete insensibility, which entitles ether to be regarded as an important anæsthetic agent; and, indeed, for some time it was the only agent used for producing Anæsthesia (q.v.) in operations, but in many places it has been entirely superseded by the employment of chloroform.

**Etheredge**, SIR GEORGE, a Restoration dramatist, was born most probably in London about 1636. Almost nothing is known of his personal history save that he must have lived much in his early life at Paris, that he studied law, was 'gentle George' and 'easy Etheredge' in the circle of Sedley and Rochester, the most brilliant young reprobates of their time, that he had an intrigue with the famous actress, Mrs Barry, afterwards settling £6000 on her daughter, was knighted and married, not with his entire good-will, to a wealthy widow, and in 1686 was sent to be Resident at the Imperial court at Ratisbon. This banishment he found intolerably tedious, but he contrived to vary its monotony with courting, moderate drinking, sometimes immoderate play, and flirtation with passing actresses, as well as with correspondence with Middleton, Dryden, Betterton, and others. Fortunately, drafts of some hundred of his letters (many of these official), along with poems and other papers, have been preserved in a letter-book acquired by the British Museum in 1837, and help to reveal to us a man of whom our knowledge otherwise would have been singularly scanty. It is not true that Etheredge broke his neck at Ratisbon in 1689, by falling down-stairs after a banquet; he seems to have died in Paris, most likely about the close of 1690. In English literature Etheredge holds a place scarcely as the founder of the comedy of intrigue, which reached its perfection in the masterpieces of Congreve and Wycherley. He himself had found his inspiration in Molière, and out of him grew that great master of comedy's English counterpart, the legitimate comedy of manners, and the dramatic triumphs of Sheridan and Goldsmith. Etheredge was more important in the impulse he gave the drama than in the magnitude of his own performance. His habitual indolence hindered him from producing more than three plays, *The Comical Revenge*; or *Love in a Tub*, the earliest play of which any large part was written in rhymed heroics (1664); *She Would if She Could* (1668); and *The Man of Mode*; or *Sir Fopling Flutter* (1676). These were all highly popular in their day, and it may be said that we have no better helps to an understanding of the time. The figures we meet are real creations, instinct with life, and some, as Dorimant and Sir Fopling Flutter, possess the supreme merit of having gone into literature as concrete types of the qualities they were meant to represent. See the fine essay on Etheredge in Edmund Gosse's *Seventeenth-century Studies* (1883), and the admirable complete edition of his works, with Introduction, by A. Wilson Verity (1888).

**Ethics** is that branch of philosophy which is concerned with human character and conduct. It deals with man as a source of action, and not merely as the subject of knowledge. It is thus brought into the closest relation with psychology, which explains the nature and origin of the mental processes of the individual, and with the investigations into the development of human customs and institutions made by the new science of sociology. In this way a number of questions arise which are in their terms psychological or sociological, although they have nearly always been discussed with a view to their ethical bearing. Such are (1) the psychological question concerning the way in which ethical or moral principles are apprehended—the question of Conscience or the moral faculty; (2) a series of inter-connected psychological questions concerning

the motives to action, or the way in which morality is realised in conduct—e.g. (a) whether reason can be a motive to action—the question of the relation of Reason to Sentiment, (b) whether motives can be reduced to a common formula in terms of pleasure and pain—the question of the relation of Pleasure to Desire, (c) whether and how far spontaneity is involved in voluntary action—the time-honoured question of Free-will; (3) a psychological question as to the way in which character is moralised—the question of the nature and relation of the Virtues. Besides these, there is (4) the historical question of the connection of moral ideas and practice with the social customs of the time, and its political, religious, and other institutions.

The preceding questions all deal with the actual facts of conduct and character—their order and historical connection. But it is characteristic of properly ethical inquiry to seek to determine the principles or end by which conduct is to be regulated. Ethics thus looks at things from a point of view foreign to the theoretical sciences. It has to do not merely with what is, but with what ought to be. This is indicated by the familiar opposition between Right and Wrong in conduct, Virtuous and Vicious in character, and in the notion of Duty, in which the human will is conceived as under an obligation to obey a certain law, or follow a certain end, which obligation, however, may or may not be fulfilled in actual conduct. This notion of moral obligation or Duty does not come to the front in the Greek philosophies, to whom the origin of our philosophical conceptions of morality is mainly due. Its present fullness of signification is largely due to legal and to religious modes of thought; and, owing to its influence, modern ethics has frequently received a distinctly legal or theological stamp—being represented as a system of duties, prescribed by God, or by Conscience, in which certain kinds of action are enjoined and others forbidden. But, underlying this notion, there is the conception of certain kinds of conduct, or certain types of character, as better than others, or preferable to them. This, at least, is involved in all ethical thought. And the attempt to reach a synthesis of what is called morally good, or to give a reason for preferring certain objects to others, necessarily leads to the inquiry after an ultimate end, which is not desired as a means to anything else, but is held to be good in itself. This is the ethical end, or Chief Good, which formed the leading subject of discussion in Greek ethics, and to the explicit investigation of which modern ethical speculation has to a large extent returned.

The nature of this chief good has been differently defined by different schools. But it was remarked by Aristotle, at a time when ethical terminology was less complex than it is now, that, in spite of their different views as to the nature of this good, all men are agreed as to its name; calling it *eudaimonia*—a term equivalent to 'well-being,' but unfortunately rendered, according to the universal tradition of translators, by the English word *happiness*. The word happiness in modern ethical discussions signifies a maximum of pleasures, or an experience in which the pleasures greatly exceed the pains. In this sense of the word, however, the assertion that the good is happiness would have been denied by Aristotle, as well as by Plato. While arguing that the good for man must be something obtainable by man, Aristotle did not find the end in pleasure, but rather in the perfect development of a man's self, in moral and intellectual excellence. But the doctrine that pleasure is the highest good was held by predecessors and contemporaries of Aristotle, and was afterwards formulated by Epicurus into an ethical theory.

This view that pleasure or happiness is the chief

good has been held in two very different forms. According to the one view, the chief good and moral end for each individual is his own happiness or pleasure; according to the other view, it is the happiness or pleasure of the community, or of mankind, or even of sentient creatures generally. The former was the doctrine of Epicurus, and has been called Egoistic Hedonism. The latter view—called Universalistic Hedonism or Utilitarianism—owes its development to modern and especially to English writers. A principle similar to that of modern utilitarianism was laid down very early in the history of English ethics. Thus, it has been pointed out that Richard Cumberland, in his treatise *De legibus Naturæ* (1672), put forward the 'common good of all' as the supreme end to which all rules of conduct are subordinate, though, according to him, this good includes perfection as well as happiness. In a similar way, Shaftesbury (*Inquiry concerning Virtue and Merit*, 1699), Joseph Butler (in his *Sermons*, 1726), and Francis Hutcheson (*System of Moral Philosophy*, 1755) speak of the 'good of society' as equivalent to virtue. But the real founder of modern utilitarianism was David Hume (*Treatise of Human Nature*, 1739; *Inquiry into the Principles of Morals*, 1751). He defined Virtue as a quality approved by the spectator, and Vice as a quality blamed or censured by the spectator, and endeavoured to show, by a review of the virtues, that the qualities approved are either immediately agreeable or useful (i.e. indirectly agreeable) to ourselves or to others. In this way, utility is made the ground of the distinction between Virtue and Vice. The *Moral Philosophy* of Paley (1785) contributed largely to define and render applicable to practice the utilitarian criterion of morality; though, in his system, the utilitarian principle is based upon an 'other-worldly' selfishness. Subsequently, utilitarianism was defended and applied to morals, politics, and law by Jeremy Bentham (1748–1832), who was surrounded by an energetic school of writers, including Ricardo, James Mill, J. S. Mill, Austin, and George Grote. J. S. Mill's remarkable essay on *Utilitarianism* (1861) is chiefly occupied with defending the theory against the popular objections to it, which had been increased rather than obliterated by Bentham's uncompromising polemics. He especially contended against the representation of utilitarianism as a selfish and a sensual theory. It is not selfish (he argued), for it requires that a man should be impartial in deciding between his own interests and those of others. It is not sensual, for man possesses faculties of a kind which sensual pleasures cannot satisfy. The being of lower faculties may have more contentment, because without the desire for anything further, but has not more pleasure or happiness. In defending this position Mill does not rely merely on the greater permanence, purity, and fruitfulness of the intellectual and social pleasures as compared with the pleasures of sense. He asserts that pleasures differ from one another in kind as well as in degree or intensity, and that the pleasure of higher quality or kind is to be preferred to one of lower quality, even although the intensity of the latter be greater than that of the former. It is now, however, generally admitted that this distinction is inconsistent with the hedonistic basis of utilitarian ethics, seeing that it makes not the pleasure itself, but that which distinguishes one pleasure from another, the real ground of moral preference.

Owing to the definiteness of its principle, and the facility (within a certain range) with which it can be applied, the utilitarian maxim admitted, in the hands of Bentham and his school, of fruitful application to political and legal questions. The proof, or philosophical basis, of the theory presents greater difficulty. Pleasure, indeed, may be obviously

desirable, though it is not so obvious that it is the ultimate or highest moral end. But it is plainly due to confusion of thought that this desirableness of pleasure is given (by J. S. Mill) as a sufficient reason for holding that the general happiness is the ethical end for the individual. The gulf between egoistic hedonism and utilitarianism requires to be bridged over. The transition from one position to the other has frequently been made by the help of religious or of political considerations. Thus the utilitarianism of Paley was founded on the belief that the happiness of mankind was the ethical end prescribed by God; that of Bentham resulted from looking at action from the point of view of the community and its interests rather than from that of the interests of the individual. In this connection, consideration is given to the sanctions of morality, or pains following the breach of moral law. These sanctions are enumerated as religious, political, social, and internal. The religious sanction is that relied on by Paley. Bentham and Mill lay greater stress on the others. But it is admitted that the political sanction does not exact from an individual beneficence, or active regard to his neighbour's happiness, but only prohibitory, or non-interference with that happiness. The social sanctions, again, are incomplete and variable, and have no exact correspondence with the utilitarian principle; while the internal sanctions depend on the individual conscience, which utilitarian writers commonly hold to be a growth in the individual mind, due to and imitating the social sanctions. The unsatisfactoriness of the proof of utilitarianism is recognised in the chief recent exposition of the theory—that in Sidgwick's *Methods of Ethics* (1874). The utilitarian theory of the moral end or standard is there associated with an intuitive theory of knowledge not usually held by utilitarians: the justification of the theory is based on the axioms of justice and benevolence, which the exhaustive examination of intuitive ethics carried out in the same work has left standing as formal axioms of the practical reason. Owing to the influence of the doctrine of evolution as applied to character, a still more radical transformation has been effected in the utilitarian theory (Spencer's *Data of Ethics*, 1879; L. Stephen's *Science of Ethics*, 1882). Applied only to the method of utilitarianism in Spencer's hands, the evolution theory has been used by other writers to show the inadequacy of the utilitarian principle; but few attempts have been made to substitute for the latter an ideal in better correspondence with the facts and laws of moral development.

Utilitarianism is a morality of consequences: finding the moral quality of conduct and character in the kind of feeling actions tend to produce in sentient beings. As this pleasant or painful feeling can only be ascertained by experience, the theory is nearly always associated with an empirical theory of the origin of our knowledge of morality. The controversies, especially of English ethics, have been largely occupied with the debate on this question between the Empirical and Intuitive schools of ethics. The latter school lays stress on the immediateness and universality of the moral judgments passed by each man's conscience. A doctrine of the Moral Sense, as a feeling, or perception, by which actions or motives were morally distinguished apart from their consequences, was developed by Shaftesbury and Hutcheson; and Butler formulated the doctrine that conscience is the supreme authority as to what is right or wrong. It is true that in Butler's *Sermons* Self-love, or a calm regard to one's interests on the whole, is frequently spoken of as co-ordinate with, and indeed, in one place, as superior to Conscience. But this is inconsistent with Butler's explicit statements even in that work, and the view

does not reappear in the *Dissertation on Virtue* appended to the *Analogy* (1736). In the latter work, also, the virtuous action which conscience prescribes is no longer asserted to be conforming with action aiming at the good or happiness of society. In this way Butler's severance from utilitarianism is complete, and he may be fitly regarded as the head of the modern intuitive school. Of this school Dr Martineau (*Types of Ethical Theory*, 1885) is a prominent representative; differing, however, from the majority of the school in holding that moral quality belongs primarily to motives, not to action. The weakness of the intuitive position, as stated by Butler and many of his successors, lies in the fact that the source of ethical principles, conscience, is not brought into intelligible relation with the rational or spiritual nature of man. Hence the force of the objection urged against Butler—that he moves in a circle, defining the right as what conscience approves, and conscience as what approves the right. The doctrine of Conscience holds an insecure position in his system, because it is unrelated to reason, because, in a word, his ethics is without foundation in metaphysics. On this account, the position has been peculiarly liable to be undermined by empirical analyses, such as Bain's attempt (*The Emotions and the Will*, 1859; *Mental and Moral Science*, 1868) to trace the growth of conscience in the individual from fear and love with a perception of utility added, or the more elaborate efforts of evolutionist writers, by whom it is represented as the result of countless experiences of the effects of action transmitted from individual to individual, until, in the form of a moral sense or conscience, they have become part of the common mental inheritance of the race. A further difficulty connected with the view of conscience held by Intuitionists is the mutual relation of the kinds of actions it approves, or of the laws for action laid down by it. Justice, veracity, beneficence, &c. are said to be its laws; but the attempt is seldom made to show how these are connected with one another.

These obvious difficulties meet at least with an attempted solution in the ethical system of Kant (*Groundwork of the Metaphysics of Morals*, 1785; *Critique of Practical Reason*, 1788). For Kant, conscience is simply practical reason; and its laws are reduced to unity. Reason, although limited in its knowledge of objects to the phenomena of sense, is yet in the practical sphere capable of laying down absolute or unconditional laws. This is shown by the moral law, with its categorical 'thou shalt,' prescribing a principle of conduct irrespective of desire or any ulterior end. Only the action which proceeds from a good will (that is, a will in accordance with moral law) is completely good. External conformity to the law gives legality; morality requires that the law, or respect for it, should be the moving principle of action. This, according to Kant, may prove to us that the will is free: 'thou shalt' implies 'thou canst.' Thus, in the order of our knowledge, it is the moral law that convinces us of freedom. But in reality the moral law is simply the law of the will itself, and the will is free when acting under its own law; it is under constraint only when influenced by the sensuous nature with which it is connected in man. The 'categorical imperative' of the moral law is expressed by Kant in the phrase, 'Act according to that maxim (or subjective principle) alone which thou canst at the same time will to be a universal law.' Reason is one in all men, and action to be rational must thus admit of being universalised. In this way reason gives a form for action. It also gives its end; for reason is an end in itself, and humanity, as rational, must therefore always be treated as an end, never as a mere means. Kant's

ethical principle remains, however, a formal principle, not admitting of the connection he sought to give it with the content of practical life. Its formality or emptiness is due to his purely formal conception of reason itself. To get rid of this formality has been the effort of the later ethical systems which have been most influenced by Kant. They base morality, as he did, on the reason or spiritual principle; but, with a less restricted view of this principle, they seek its content and realisation in practical life and its institutions. This position, largely due to Hegel, has been worked out independently in the most important recent English work of speculative ethics—T. H. Green's *Prolegomena to Ethics* (1883). 'The ultimate standard of worth is,' according to Green, 'an ideal of personal worth,' while, at the same time, 'it is equally true that the human spirit can only realise itself, or fulfil its idea, in persons, and that it can only do this through society, since society is the condition of the development of a personality.' It thus appears that at the present time the two leading ethical schools in Britain may both be called evolutionist—the one, that just described, looking upon morality as the gradual realisation of a spiritual principle in the forms and institutions of domestic, civic, and political life; the other holding that the evolution is a merely natural one, and giving the name morality to those habits of acting which have contributed to the preservation and development of the race. The former theory is connected historically with intuitionism, the latter with utilitarianism. Neither is able to give so precise a definition of the moral ideal as was attempted by the older theories; and it may be admitted, perhaps consistently, by both sides (though with some difference of meaning under the similarity of phrase), that no such precise definition is possible, but that our apprehension of the ideal itself becomes clearer and fuller as it is progressively realised in the individual life and in society.

Some of the more important ethical writings, of different schools, have been already mentioned. The best introduction to the history of the subject is Sidgwick's *Outlines of the History of Ethics for English Readers* (1886). See articles on the great ethical thinkers, ARISTOTLE, EPICURUS, STOICS, BUTLER, KANT, &c.; also EVOLUTION.

**Ethiopia**, the biblical *Kush*. Originally, all the nations inhabiting the southern part of the globe, as known to the ancients, or rather all men of dark-brown or black colour, were called Ethiopians (assumed by the Greeks to be from the two Greek words *aitiō*—*ops*, and to mean 'sunburned'; but it may be possibly a form of an unknown Egyptian word). Later, this name was given more particularly to the inhabitants of the countries south of Libya and Egypt, on the Upper Nile, extending from 10° to 25° N. lat., 28° to 40° E. long.—the present Nubia, Sennar, Kordofan, Abyssinia. The accounts which the ancients have left us with respect to this people are, even where they are not of an entirely fabulous nature, extremely scanty and untrustworthy, as both Greeks and Romans never got beyond Napata, 19° N. lat. From the Homeric age down to Ptolemy, these regions were understood to be peopled by Pygmies, Troglodytes ('dwellers in caverns'), Bleumnyes ('hideous men'), Macrobii ('long-lived men'), &c., besides being divided into the lands of cinnamon, myrrh, of elephant-eaters, fish-eaters, tortoise-eaters, serpent-eaters, &c. Homer frequently refers to the 'blameless Ethiopians.' The only portion of ancient records which does contain something akin to historical accounts is that which refers to Meroë, an island formed by the rivers Astaphus and Astaboras, tributaries of the Nile. There stood, from time immemorial, an oracle of Jupiter

Ammon. This and the central portion of the island, together with the extraordinary fertility of its soil, the abundance of animals, metals, &c., made it not only the chief place of resort for all the inhabitants of the adjacent parts, especially the numerous nomad tribes, but also the emporium for India, Arabia, Ethiopia, Egypt, Libya, and Carthage. Thus it grew so rapidly that about 1000 B.C. it counted among the most powerful states of the ancient world; and about 760, having ever since Sesostris been tributary to Egypt, it succeeded, under Sabacus, in shaking off the Egyptian yoke, and continued, in its turn, to hold Egypt for about sixty years. During the reign of Psammetichus, 240,000 Egyptians settled in Meroë, which, the greater part of the immigrants being artisans, traders, &c., rose still higher. Many new cities were built, and the state was in the most flourishing condition when it was conquered by Cambyses, about 530 B.C. He fortified the capital town, and called it Meroë. After the destruction of Thebes by Cambyses, most of the inhabitants of that city took refuge there, and made the country still more Egyptian. Ergamenes transformed its theocracy into a military monarchy in the 3d century. Under Augustus, Meroë was conquered, and a Queen Candace is mentioned as his vassal. Under Nero nothing but ruins marked the place of this once powerful and highly civilised state. Up to this day remnants of mighty buildings, covered with sculptures—representations of priestly ceremonies, battles, &c.—and half-defaced inscriptions hewn in rocks, besides rows of broken sphinxes and colossi, are frequently met with in those parts.

According to the scanty native chronicles, the son of Solomon and the Queen of Sheba (Makeda as they, Balkis as the Arabian historians call her), named Menilelek, was the first king of the Ethiopians. Few kings' names occur up to the time of Christ, when Bazan occupied the throne. The missionary Frumentius (330) found two brothers (Christians) reigning—Abreha and Azeba. During the time of the Greek emperor Justin (522), King Elezbaas destroyed the state of the Homerites in Asia, in order to revenge their persecutions of Christians, and was canonised. From 960 to 1300 another dynasty, the Zagwean, held the chief power, all the members of the Solomonic dynasty, save one, having been murdered by Esal, who made her son king. In 1300 Ikon-Amlak, a descendant of this one scion of the house of David, regained possession of the throne. The history of the country, down to the reign of the Negus John (killed near Galabat in May 1889, in battle with the dervishes), is given under ABYSSINIA.

Emigrants from the other side of the Arabian isthmus, as were, beyond doubt, the earliest settlers in Ethiopia, it is but natural that the structure of their language, as well as that of their own bodies, should bear traces of their Semitic origin. The fact of this emigration is expressed in the very name of this language, which is called *Ge'ez*—possibly 'free,' affording a parallel to the designation *Franc*—French, though more probably the word means 'migration,' hence 'emigrants.' The name Ethiopia, or, as they call it, *Ityōpiā* (adj. *Ityōpiāwī*), they adopted from the Greeks at a very late period. This their oldest language, *Lesāna Ge'ez*, was suppressed by a royal decree of Ikon-Amlak, in the 14th century, and the Amharic adopted as the court language. Ever since, it has, with exception of the province of Tigré, where it is still spoken (with slight idiomatic changes), remained the *Lesāna Mazhaf*, the language of books and of the church. It is exclusively used in writing, even of ordinary letters, and the educated alone understand it. Its general structure comes as close to that of the Arabic as a sister-dialect can

and must. A great many of its words are still classical Arabic; others resemble more the Hebrew and the Aramaic; others, again, belong to African dialects; and many, as the names of the months,

እስመ : ከመዝ : አፋቀር : እግዚአ  
ብሔር : ለዓለም : እስከ : ወልደ :  
ቀሕደ : ወሀበ : ቢዛ : ከመ : ከሉሉ :  
ዘየአምነ : ቦቱ : እደተሐገሉ : አላ :  
ደረክብ : ሕይወተ : ዘለዓለም ::

The text John, iii. 16, in Ethiopic, as printed by the British and Foreign Bible Society.

are Greek. It has twenty-six letters, twenty-two of which bear the ancient Semitic stamp, and exhibit the greatest likeness to the Phœnician—the common original alphabet—though no doubt derived immediately from the Sabæan or South Arabic alphabet (see ALPHABET). There are seven vowels, including a very short *e*, which sounds precisely like the Hebrew *Shēva*, when open, and like *e* in 'men,' when shut. These vowels are represented by little hooks, and remain inseparably attached to their respective letters; and as the Ge'ez, unlike all its sister-languages, is never written without vowels, the alphabet becomes a syllabary with 182 characters. In addition to this, four consonants (*g*, *k*, and *h* sounds) interject a *u* sound before the principal vowel, *qua*, *gui*, *guē*, &c. Another difference exists in its being written from left to right—a circumstance from which some have concluded that the Greeks introduced writing in Ethiopia; forgetting, in the first place, that Greek itself was frequently written from right to left, and that Zend, certain cuneiforms, hieroglyphs, &c. are likewise written from left to right. As was to be expected among emigrants from South Arabia, the verbal system has most resemblances to the Arabic, although it differs from this, and agrees with Aramaic, in discarding the passive and using for it the reflexive; there is a double infinitive, only a passive participle and participial words formed by *m* prefixed; traces of a dual remain, though it is no more in use; the formation of the so-called broken plural, and of declension generally, a special accusative termination, the distinction of the subjunctive from the imperfect, and other peculiarities distinguish the Ge'ez from the Northern Semitic, while the want of the article distinguishes it from Arabic; and in power to subordinate clauses by means of particles and form a concatenated sentence it is superior to all other Semitic dialects. There are no diacritical marks employed in writing; the letters are not combined, and the words are separated by two dots.

Although there may have been some literature in a flourishing country like Ethiopia anterior to Christ, still, owing both to frequent internal convulsions and other causes, no traces of it remain, even the few inscriptions that have been found being of the Christian age. The earliest existing document of post-Christian literature is a complete translation of the Bible, according to tradition by Frumentius, most probably by missionaries from the north, whose native language was Aramaean (see FRUMENTIUS). The Old Testament, a translation from the Alexandrine version, or LXX., consists of four parts: (1) the Law or Octateuchos (five books of Moses, Joshua, Judges, Ruth); (2) Kings; (3) Solomon; (4) Prophets, and two books of the Maccabees. The New Testament consists of: (1) Gospels; (2) Acts; (3) Paulus; (4) Apostolus. The Book of Enoch belongs also to

the literature of the Old Testament (see ENOCH), besides the Book of Jubilees, the Ascension of Isaiah, and some others. The New Testament comprises the Shepherd of Hermas, and likewise another book, Synodos, containing the pseudo-Clementine or Apostolical Constitutions, in two recensions, with the Apostolic Canons, the canons of various councils, and much other matter. The Ethiopians have a liturgy (*Kanon Kedās*—'Holy Canon'), and a symbolico-dogmatical work (*Haimanōta Abau*—'Belief of the Fathers'), containing portions of homilies of the Greek Fathers, Athanasius, Basil the Great, Chrysostom, Cyril, Gregory of Nyssa, and Gregory Nazianzen. Besides these they have martyrologies, called *Seneksār* (Synaxaria). They employ in this their sacred literature a peculiar kind of rhythm without a distinct metre. Any number of rhyming lines forms a stanza, without reference to the number of words constituting the verse, or of verses constituting the stanza. They also use certain phrases as a refrain. Ethiopic literature consists chiefly of translations, in earlier times from the Greek, and more recently from the Arabic. In the translations from Greek some interesting works have been preserved which had otherwise disappeared—e.g. the Book of Enoch. Among the translations from the Arabic are books of philosophy, medicine, jurisprudence, and history. The native literature consists chiefly of sacred poetry and chronicles, among the last the *Gloria Regum* (*Kebra Nagast*), a work in praise of Axum and the royal family of Ethiopia (*Chronicle of Axum*). They are very fond, however, of riddles, wise saws, and the like, so fascinating to the Eastern mind. They have native vocabularies, Ethiopic and Amharic, though not of great value to the modern lexicographer. No wonder the learned in Europe should have been sorely puzzled by such a language, and that they should, after long consideration, have pronounced it to be either 'Chaldee' or 'Indian,' while Bruce held it to be the language of Adam and Eve. Potken, a Cologne church-dignitary, happening to be at Rome at the beginning of the 16th century, there made the acquaintance of native Ethiopians, and became the first to enlighten the world on the nature of this occult language. After him came the Carmelite Jacob Marianus Victorinus from Reate, who wrote *Institutiones Linguae Chaldaicae seu Ethiop.* (Rome, 1548), an entirely worthless book; then Weimmers, who in 1683 published an Ethiopian grammar and dictionary. The principal investigator, however, was Job Ludolf from Gotha, who, aided by the Abba Gregorius, and supported by his own extraordinary linguistic talents and indomitable energy, acquired such a power over this language that, notwithstanding the number of eminent Orientalists, such as Platt, Lawrence, Dorn, Innpfeld, Hoffmann, Roediger, Ewald, Isenberg, Blumenbach, Dillmann, &c., who have since worked in this field, his books still hold their own place. It is hardly necessary to add that the Ethiopic is one of the most important and indispensable languages to the Semitic scholar.

The great advances made in Ethiopic studies in recent years have greatly superseded earlier works. (1) Texts: *The Psalter*, by Potken (Rome, 1513, 1518); by Ludolf (Frank, 1701, and often). *The Gospels* (Lond. 1826); *New Testament* (Lond. 1830), both by T. Pell Platt (already in Walton's Polyglott); *Jonah* in 4 oriental versions, by W. Wright (Lond. 1857); *Joel*, by Dillmann (in *Merx. Comm. on Joel*) (1879); *The Old Testament* (vol. i. 1853; vol. ii. 1861-71), by Dillmann. Dillmann has also edited the following: *The Book of Enoch* (1851; previously by Lawrence, Oxford, 1838; recent Eng. trans. by G. H. Schoedde); *the Ascension of Isaiah* (1877; previously by Lawrence, Oxford, 1819); *the Book of Jubilees*, or *Little Genesis* (1859). *The Pastor of Hermas*, by D'Abbadie

(1860); the *Ethiopian Dilascalia*, or *Apost. Constitutions*, by T. Pell Platt (1834). Besides these, various texts have been edited, including some parts of the secular literature. (2) Grammars and Dictionaries: Ludolf, *Gramm. Eth.* (Frank. 1702); Dillmann, *Gramm. d. Aeth. Sprache* (Leip. 1857); good small grammar by Prætorius (Leip. 1886); Ludolf, *Lec. Eth. Lat.* (Frank. 1699); Dillmann, *Lec. Ling. Eth.* (Leip. 1855); *Chrestomathy*, by same (Leip. 1856). The ancient Ge'ez is now represented by various dialects: (1) by the Tigré, which has best preserved the features of the original language, spoken in the north-east of Abyssinia, and particularly by populations just outside the north border of the kingdom; vocabulary by Munzinger in Dillmann's *Lexicon*; (2) by the Tigriña, or, more properly, Tigrā, spoken about Axum, the ancient seat of the kingdom, which, however, has suffered more from the influence of Amharic (Prætorius, *Gramm. d. Tigriña Sprache*, Halle, 1871; Schreiber, *Manuel de la langue Tigrā*, Vienna, 1887); (3) by the Amharic, the state language since end of 13th century, and extending far to the south, which has drawn into itself a multitude of elements from the African languages, and developed many forms altogether alien to Semitic (*Grammar and Dictionary* by Isenberg, Lond. 1841; Prætorius, *Gramm. d. Amh. Sprache*, Halle, 1879; *Dictionnaire de la langue Amariña*, par D'Abbadie, Paris, 1881). Since the English expedition to Abyssinia, the British Museum possesses a larger number of Ethiopic MSS. than any other library. Catalogue of Ethiopic MSS. in British Museum (Lond. 1847); Catalogue of Ethiopic MSS. in Bodleian, (Oxford, 1848), both by Dillmann; Catalogue of Ethiopic MSS. in British Museum, acquired since 1847, by W. Wright (Lond. 1877), including the Magdala Collection.

**Ethiops**, or **ÆTHIOPS** (Gr. *aitḥō*, 'I burn,' and *ops*, 'countenance'), is a term applied by the ancient chemists to certain oxides and sulphides of the metals which possessed a dull, dingy, or black appearance. Thus, *Ethiops Martialis* was the mixture of protoxide and peroxide of iron known as the black oxide.

**Ethmoid Bone**, THE (so called from *ethmos*, 'a sieve'), is one of the eight bones which collectively form the cranial box. It is of a somewhat conical form, and enters into the formation of the cranium, the orbits, and the nasal fossæ. See NOSE.

**Ethnology**, one of the numerous sciences, such as Anthropology, Philology, Psychology, and Sociology, which collectively constitute the complete study of man. But, owing to its comparatively recent origin, much diversity of opinion continues to prevail regarding the proper scope and limits of this branch of the subject. Thus, while Powell declares that 'there is no science of ethnology,' Adolf Bastian regards it as the 'sister' of anthropology, the latter dealing with the physical, the former with the psychic element in man. Between these extremes lie the more moderate and now largely accepted views of those who, with Broca, Latham, Topinard, Littré, De Quatrefages, and many others, regard anthropology as the science of man as distinguished from his nearest congeners in the animal kingdom—the bimanus as opposed to the quadrumanus—and ethnology as the science of man as a genus in relation to its more or less numerous species, or as a species in relation to its more or less numerous varieties. Thus, 'anthropology determines the relations of man to the other mammalia; ethnology, the relations of the different varieties of mankind to each other. . . . The simple record of facts constitutes ethnography, or descriptive ethnology' (Latham). 'Ethnology treats of the origin and distribution of peoples, ethnography of their description' (Littré). 'Medicine studies individuals; ethnography, peoples; ethnology, races; and general anthropology, man as a whole and in his relations to animals' (Broca).

As thus defined, and as also understood by this writer, ethnology embraces a comparative study

of the various races of mankind, their origin, physical and mental differences, dispersion, geographical distribution and interminglings, leaving human speech to philology, human culture (political and social institutions, usages, traditions, folklore, religion) to sociology—i.e. the science of man as a *zōon politikon* (Aristotle). These limitations have been necessitated by the continuous tendency of the sciences, as well as of the arts, to 'division of labour,' as here shown by the entirely independent development of philology, and by the recent creation of sociology, for which Herbert Spencer already claims the rank of a science. Nevertheless, such limitations cannot be always rigidly adhered to, and in dealing with such a complex theme as the human family there must necessarily arise certain collisions, so to say, certain overlappings in the direction of all the allied sciences. Thus, to give one instance, the important and much agitated question of language as a racial test could not be at all disensed without some reference to such strictly philological subjects as the origin and growth of articulate speech.

In accordance with the foregoing statement, the main points with which we are here concerned are the origin, nature, number, and distribution of the present human races, where the first question that presents itself is the specific unity or diversity of mankind. From the very nature of the case, this is a question that can never be decided one way or the other with absolute certainty. But the general tendency of modern inquiry points to the conclusion that the poet's 'one touch of nature,' which 'makes the whole world kin,' was not merely inspired by a vague sentiment, but rests on a solid foundation of fact. The physical and mental qualities characteristic of the leading types are not considered as sufficiently marked to constitute so many distinct species, while the now fairly established fact that all are mutually fertile between themselves is held to be all but conclusive of their primordial unity (Flower, Tylor). Hence the monogenist doctrine, which otherwise accords with orthodox belief, is daily gaining ground on the polygenist views, which were based partly on the erroneous assumption of the permanency of types (fixity of species), partly on the brief record of the Mosiac cosmogony, which certainly did not allow sufficient time for the differentiation of the existing human varieties. But this difficulty is now removed by the results of recent research, which place beyond all doubt the existence of Linnaeus's *homo sapiens* in early quaternary, if not even in late tertiary times (see MAN). Since then there has been ample time for the upward evolution even of the semi-simian pre-glacial 'men of Spy,' contemporaries of *Rhinoceros tichorinus*, and of *Elephas primigenius*. (Their remains were discovered in 1886 by MM. Lohest and De Puydt in a cave on the banks of the Orneau, commune of Spy, Namur, Belgium).

Apparently a more serious objection to the monogenist theory is based by Friedrich Müller, Professor Sayce, and others on the admittedly fundamental diversity of linguistic families. Thus is again raised the whole question of the relations of language to ethnology, a question by which this science has been from the first and still is unreasonably beset. It is argued that, if the languages of primitive peoples are radically distinct, the peoples themselves must have different origins; and, while some suggest twelve or more independent physical and linguistic groups, others attempt to avoid the seeming difficulty by supposing that, if originally one, the chief physical groups were differentiated before the evolution of speech, which was consequently independently evolved after dispersion of

*homo alalus* in so many independent geographical centres. But it is obvious, in the first place, that neither of these assumptions removes the difficulty; for if every fundamentally distinct linguistic presupposes a fundamentally distinct physical stock, then these latter must be reckoned not by units or tens, but by many hundreds, philology having clearly shown that, even excluding many extinct tongues, the radically different existing stock languages do not fall far short of a thousand. We have here therefore a *reductio ad absurdum*, and the assumption that physical and linguistic types coincide must be absolutely rejected. With its rejection is cleared away a fruitful source of endless confusion in ethnological studies. It follows, in the second place, that the difficulty itself is purely fanciful; for, if physical and linguistic types need not coincide, it is evident that within a given physical group we may have an indefinite number of independent linguistic groups. The further consideration that language changes much more rapidly than physique, a proposition that has become a commonplace with all anthropologists, leads us to expect that the relation must in fact be as here stated. Since the remote epoch when Haeckel's *homo primigenius alalus* ('speechless man') became Linnaeus's *homo sapiens* endowed with speech and reason, there has been time for the development of several more or less marked physical varieties. Consequently, there has been also time for the more complete development of a much larger number of linguistic forms, the existence of which is thus no longer antagonistic to the primordial unity of mankind.

How this unity became diversified within certain relatively narrow limits is a question which, strictly speaking, belongs to the domain of Evolution (q.v.). It is the province of ethnology to study the varieties as they are, to determine their number, character, and mutual relations, with a view to an ultimate classification of all existing human groups. Here one point, that of mixture, requires to be all the more specially emphasised, as it is usually the less attended to by writers on this difficult branch of the subject. It may be stated broadly that, after the first more or less marked differentiations, whether due to the outward influences of the environment, to natural selection, the struggle for existence, the correlation of parts, or all these combined, all subsequent modifications have been mainly caused by incessant intermingling, and consequently that there are no longer any pure races in existence. (One may perhaps except a few isolated groups, such as the Andamanese Islanders, the Kai Colos of Fiji, the Ainos of Yesso, the Fuegian Kahgans, and till recently the Tasmanians, completely extinct since 1876; but the statement may be accepted as substantially true.) Long isolation in new centres exposed to new conditions of life would undoubtedly tend to fix changes gradually brought about by natural causes. But, as the earth became more densely peopled, fresh shiftings necessarily arose, colonies were thrown off, contact and collision between the earliest evolved varieties became inevitable. To the influences of the surroundings were thus added the far more potent effects of crossings, and the development of fresh types and sub-varieties of all sorts proceeded at an accelerated rate. This process was necessarily continued down to the present time, resulting in ever-increasing confusion of fundamental elements, and blurring of primordial types.

To this confusion and blurring must be attributed the great difficulty now felt in determining the number and the distinctive characteristics of the original human stocks, and the amazing diversity of views that has always prevailed on this subject.

It cannot even be asserted that what we call the main divisions, the primary groups, are themselves original even in their ideal conception, and not the outcome of still more remote and earlier fusions. Who shall say that the dirty yellow tinge, for instance, of the average Chinese is not the result of a blend, as the light brown of the eastern Polynesians certainly appears to be?

This brings us to the consideration of the so-called 'ethnical criteria'—i.e. the various factors on which ethnologists rely in their different schemes of classification. These criteria are partly internal or anatomical—the skeleton in general, and particularly the cranium; partly external—colour of skin, colour and texture of hair, and such other determining elements, whether physical or mental, as may be studied on the living subject. Although opinion varies considerably as to the value of these several characteristics, there is a general consensus in attaching special, if not permanent, importance to the three elements of colour, hair, and form of the skull. Of these colour, probably because the most conspicuous feature, was the first to be considered, and formed the basis of all the early classifications, such as those of F. Bernier (1672), who distinguished four radical types—European White, African Black, Asiatic Yellow, and Northern Lapp; of Linnaeus (1738-83), whose *homo sapiens* comprised four species—the light-skinned European, the yellow Asiatic, the black African, and brown or tawny American; and of Blumenbach (1752-1840), whose groupings fluctuated, but whose terminology (Caucasic, Mongolic, &c.) has been largely retained.

Then followed a chaotic interval, during which almost every writer proposed with equal confidence a fresh division of the primary human groups. During this period, ethnology, in common with other studies affording large scope for the exercise of the imaginative faculties, became the battleground rather of partisans than of men of science. The wildest theories on the specific unity or disparity of mankind, the permanence or evanescence of types, the innate capacity or incapacity for progress, and so forth, were advocated, often with much erudition, but little common sense, by Nott and Gliddon, Morton, Knox, even Cuvier and Agassiz, apparently more eager to further their peculiar political and religious views than to promote the cause of truth. Some of these theories were even self-destructive, as for instance those of Agassiz on unity of species and difference of origin. Most of them are now interesting only to the historian of mental aberration, and, their standpoint being mainly polemical rather than scientific, they did little to advance ethnological studies.

Order was at last restored by the craniological school, founded by the elder Retzius (1796-1860), which made the shape of the head the basis of all classification, and thus introduced exact methods into this branch of the subject. The result has shown that craniology alone cannot be depended upon to supply sufficient, or even altogether trustworthy, materials for distinguishing the main divisions of mankind. Its chief elements, such as dolichocephaly and brachycephaly (i.e. length or shortness of the skull as measured from front to back), orthognathism and prognathism (less or greater projection of the jaws), are not constant in any given groups, and in many cases the most surprising diversity prevails where some degree of uniformity might be expected. Thus, the Eskimos, grouped with the more or less brachycephalic Mongol division, are marked by extreme dolichocephaly; the extinct Tasmanians, belonging to the prognathic Negro division, were highly orthognathic; no norma, either of gnathism or cephalism, can be established for the Oceanic Malay and Papuan races,

while every shade of cephalism prevails amongst the Caucasian peoples. Nevertheless, craniology can be neglected by no ethnologist, and its study has already thrown much light on various departments of anthropological science. See SKULL.

Of late years the colour and texture of the hair, the value of which had been anticipated by Linnæus, have steadily risen in the estimation of naturalists as a racial test. It is now regarded as the most constant of all the physical features, and has been made the foundation of their groupings by some of the most eminent modern anthropologists, such as Huxley, Fr. Müller, Haeckel, and Broca. Its constancy is shown by the Negro division, all branches of which, without any exception, have black and more or less frizzly hair, flat or highly elliptical in section; and by the Mongol division, which, including all the American aborigines, is uniformly characterised by straight black hair of the horse-tail type, cylindrical in section. In the Caucasian division this feature varies considerably, but still within certain limits. Thus, it may be straight, wavy, or curly, but never frizzly; the colour also may range from jet black through all shades of brown, and even red, to the lightest flaxen; but there still appears to be a certain correlation on the one hand between the black hair and dark complexion, on the other between the light hair and fair complexion of the two well-marked branches of the Caucasian division.

The other ethnical elements, whether physical or mental, are of little value taken apart, but are often useful aids in combination with themselves, and especially with the three above specified criteria. Such are stature; the shape, colour, and position of the eye; the weight or volume of the brain (cranial capacity); the form of the nose—remarkably constant in some groups; the form of mouth and lips; the superciliary and zygomatic arches, and all such other elements as collectively constitute the broad flat features of the lower, the oval and regular of the higher races—Kollmann's *champrosope* and *leptoprosope* types. Of mental or intellectual criteria immeasurably the most important is language, which, however, has had the misfortune of suffering from friends and foes alike, philologists rating it much too high, anthropologists depreciating it to a corresponding extent. Yet that speech cannot be neglected, even by the purely anthropological student, is obvious from the fact that different phonetic systems often involve different anatomical structure of the vocal organs. Owing to these differences, Europeans find it impossible, even after years of residence amongst the natives, to pronounce the various clicks of Bushman, Hottentot, and Zulu-Kafir tongues, or the many rasping sounds of the Tlinkit, Apache, and other American idioms. The 'absolute impossibility' of imitating certain tones in the Papuan languages of New Guinea is by Miklukho Maalay rightly attributed to 'fundamental differences in the anatomical structure of the larynx, and the whole innervated system of the organs of speech in the two races' (European and Melanesian). And he adds that 'not only the organ of speech, but also that of hearing, plays an important part, for the same word may be heard in a totally different manner by different persons' (*Ethnologische Bemerkungen*). Neither the Jews nor the African negroes in America have yet learned to correctly pronounce the European languages spoken by them as their mother-tongues for many generations. At the same time, 'philology and ethnology are not convertible terms' (Sayce), and extreme caution must always be used in the treatment of language as an ethnical test. It is a helpmate which, in the hands of uncritical writers, has too often proved a pitfall.

Of other mental or moral criteria it will suffice

here to mention *religion*, which, owing to the fundamental unity of the psychic element in man, can never be regarded as a true test of race, and *social pursuits*, such as the chase, pasture, and agriculture. On the latter point much misconception prevails, and it is especially a mistake to suppose that the order of progress is necessarily from the hunting through the pastoral to the agricultural state. Some of the lowest African tribes are, and always have been, tillers of the soil, while other peoples, such as the Kirghiz and Kal-mucks, ranking much higher in the social scale, are still nomad pastors. These pursuits, in fact, are questions not of race, but of the outward conditions of soil and climate, as we see in the Arabian peninsula, where the stock-breeders of the Nejd plateau become skilful husbandmen in the Yemen uplands.

Basing their conclusions on the comparative study of all these ethnical criteria, the most eminent naturalists, from Linnæus and Blumenbach to Huxley, Virchow, Flower, Broca, and Topinard, mainly agree in classifying the whole human family in three or at most four fundamental divisions. From the foregoing exposition of the subject, it follows of itself that all classifications must be regarded not as *genetical*—i.e. divisions according to common descent, but rather as groupings according to physical and mental resemblances. It also follows that the term *fundamental* is to be understood not absolutely, but only in a relative sense; for all races (this term being here taken as practically equivalent to 'breeds' or 'varieties') are necessarily regarded as belonging to a common primeval stock, constituting a single species. At the same time it does not follow that all must necessarily be supposed to have sprung from a single human pair. On the contrary, the more natural assumption would seem to be a gradual upheaval, so to say—i.e. the slow evolution of a whole anthropoid group spread over a more or less extensive geographical area, in a warm or genial climate, where the disappearance of an original hairy coat would be rather an advantage than otherwise. This view of gradual ascent in a more or less homogeneous mass has the advantage of obviating the many difficulties connected with *unity of species and unity of descent*, which are now seen no longer to be identical expressions. It also allows for differences in the physical habitus *from the first*, these differences, however slight, helping in combination with altered environments to account for the divergences that have in the course of ages resulted in the present fundamental human types. Thus, we no longer require to ask ourselves, for instance, whether the black hue shaded into the yellow, the brown into the white; whether prognathism grew into orthognathism, brachycephalic or round into dolichocephalic or long heads, and so on. None of these extremes, but only the germs of all, need be assumed as starting-points; and it is not a little remarkable that the Andamanese Islanders, declared by the highest authority to be 'the most infantile' of human races, are also amongst the least marked in these respects. Their colour is dark, but far from black; their prognathism is not pronounced; their stature is low, but not dwarfish—4 feet 10 inches as compared with the Akka, 4 feet 6 inches, and Batwa, 4 feet 3 inches (Wissmann, Flower, Man). The existing marked types may therefore be taken as collateral developments rather than independent primordial conditions, or gradual modifications of any one extreme type.

The difficulty of determining the exact number of these types is due to the fact, already pointed out by Blumenbach, that none of them are found in what may be called ideal perfection, but that all

tend to merge by imperceptible degrees in each other. But the issue now appears to be narrowed down to a choice between three, four, or at most five primary groups, with one or more marked subdivisions in each. These are the black, frizzly-haired *Ethiopic* (*Negro*); the yellow, lank-haired *Mongolic*; the white, smooth-haired *Caucasic*; the coppery, lank and long-haired *American*; and the brown, straight-haired *Malayo-Polynesian*. But the last is commonly rejected as evidently the outcome of comparatively recent mixture, in which the Mongolic elements predominate. In fact, the Oceanic Malays proper cannot be separated anthropologically from the Asiatic Mongol group. Most authorities also regard the American as a remote branch of the same group, and this view seems justified by the striking Mongolic features occurring in every part of the New World, as amongst the Utahs of the western States and the Botocudos of eastern Brazil. We are thus reduced to the three first-mentioned divisions, a grouping again adopted by Professor Flower (1885), who concludes that

primitive man has in the course of ages become differentiated into 'the three extreme types represented by the Caucasian of Europe, the Mongolian of Asia, and the Ethiopian of Africa, and that all existing members of the species can be ranged around these types, or somewhere or other between them.' But it is not to be supposed that all the distinctive characters of these three types are found co-existing in any considerable masses of the several groups. The ideal *homo Ethiopicus*, *Mongolicus*, and *Caucasicus* must therefore be constructed, so to say, by a sort of eclectic process, by selecting and grouping together the more salient features assumed to be characteristic of each. In this way has been prepared the subjoined comparative scheme of the three main divisions, the points of contrast or resemblance between which will be best shown by their juxtaposition. Here it should be noticed that the Caucasian is divided by Huxley into two distinct branches—the Xanthochroi, or fair, and the Melanochroi, or dark—which in this table are respectively indicated as 1 and 2.

TABLE OF THE CHIEF CHARACTERISTICS OF THE THREE FUNDAMENTAL HUMAN TYPES.

	Ethiopic.	Mongolic	Caucasic.
COLOUR AND CHARACTER OF SKIN .....	Blackish, sometimes almost sooty black; velvety and cool to the touch, emitting a distinct odour.	Yellowish, passing into olive, and almost every shade of brown; rough in texture; often with a <i>fade</i> , washed-out look.	Whitish; (1) very florid or ruddy; transparent, clearly showing the veins; (2) pale, but often dusky or swarthy; both merging in some places in a light olive, in others in various shades of brown.
HAIR AND BEARD.....	Jet black, frizzly or 'woolly,' rather short; flat in transverse section; sometimes said to grow in separate tufts; scant or no beard.	Dull black, coarse, lank, lustreless, sometimes (in America) very long; round in section; moustache developed; beard scant or absent.	(1) Flaxen, light brown, and even red, long, wavy, and silky; (2) black or dark brown, rather straight, but sometimes lanky or curly; both oval in section; both with full beard.
SKULL AND FACE.....	Skull mainly dolichocephalic (long and narrow), sometimes also very high (hyperstenocephalic); prognathous lower jaw; high cheek-bone; large, black, round, and prominent eye, with yellowish corners; broad flat nose; thick, everted lips, showing the red inner skin.	Skull mainly brachycephalic (round, but never quite circular); mesognathous jaw; large cheek-bone; narrow, almond-shaped, black eye, slightly oblique; very small, concave nose; features generally broad and full, something like bat-shaped.	(1) Skull mainly dolichocephalic; (2) mainly brachycephalic; both orthognathous; (1) eye blue, hazel, or brown; (2) eye large, black, and bright. Both long, straight nose, often arched or aquiline; small mouth, thinish lips; features mainly oval and regular.
STATURE AND FIGURE...	Generally tall, rather above the average, ranging from 5 feet 6 inches to 5 feet 10 inches and even 6 feet; large, bony frame, stout and robust, but weak in lower extremities.	Generally short, rather below the average, 5 feet to 5 feet 6 or 7 inches; but American branch often very tall; heavy, squat, angular frame, especially on the uplands (Tibet, Bolivia).	(1) Tall, above the average, 5 feet 6 inches to 5 feet 10 inches and 6 feet; (2) below the average, 5 feet 2 inches to 5 feet 6 or 7 inches; but much diversity within each group. (1) Powerful bony frames, often very strong; (2) lithe, active frames, often with much staying power (Jasques).
TEMPERAMENT.....	Sensuous, unintellectual, cheerful, and even boisterous, but fitful, passing suddenly from comedy to tragedy; hence at once affectionate and cruel; science, art, and letters undeveloped.	Sluggish, somewhat morose and taciturn; hence passive, with little initiative, but with great power of endurance, and subject at times to vehement outbursts; science slightly, art and letters moderately developed.	Highly imaginative, active and enterprising; hence at once spendthrift and practical; (1) somewhat solid, serious and persevering; (2) fiery, impulsive, but inconstant. Science, art, and letters highly developed in both.
LANGUAGE.....	All agglutinating, mostly with prefixes and alliterative harmony (Bantu); relatively few abstract terms.	Some isolating and uninflected, with tendency to monosyllabism and tone; some agglutinating, mostly with postfixes and vowel harmony; some polysynthetic; abstract terms numerous.	Nearly all inflecting, mainly by postfixes completely merged in modified root; hence more or less synthetic, with a general tendency towards analysis; abstract terms practically unlimited.
RELIGION.....	Non-theistic; nature-worship, with fetishism and witchcraft as conspicuous elements.	Polytheistic; spirit-worship (Animism); belief in dreams and visions (Shamanism); also Buddhism.	Monothestic (Unitarian, Trinitarian), with creeds based on revelations; priesthood (mediation) a prominent feature; also Brahmanism.

Subjoined is a brief summary of the main divisions and subdivisions of these three fundamental groups.

I. THE ETHIOPIC GROUP falls naturally into a western or African, and an eastern or Oceanic division. The western, occupying all Africa from the Sahara southwards, comprises a northern or *Soudanese* branch (African Negroes proper), and a southern or *Bantu* branch (more or less mixed Negro and Negroid populations), reaching north-

wards to about 5° N. lat. The former are marked by considerable physical unity and great linguistic diversity; the latter by almost absolute linguistic unity (Bantu languages) and great physical diversity. The chief members of the Soudanese branch are Mandingar, Wolof, Foulpy, Sonrhait, Hausa, Egbe, Ibo, Yoruba, Fanti, Nupe, Michi Batta (West Soudan, Upper Guinea, Adamawa); Kanuri, Kanembu, Tibu (?), Mosgn, Yedina,

Bagirmi, Maba (Central Soudan, East Sahara, Wadai); Shilluk, Nuba, Dinka, Janghey, Bongo, Bari, Monbuttu, Zandeh (East Soudan, White Nile, and Welle-Mobanji basins); Masai, Kavirondo, Elgeyo, Samburn (Masai Land, Lake Rudolph). The chief members of the Bantu branch are Wa-Pokomo, Wa-Sambara, Wa-Chaga, Wa-Swahili, Wa-Zaramo, Wa-Sagara, Wa-Nyam-ezi, Wa-Gogo, Ma-Nyanja, Ma-Kua, Ma-Vita, Ajawa (eastern seaboard); Zulu-Kafir, Ba-Suto, Be-Chuana, Tonga, Ba-Rotse, Mashona, Ba-Yeye, Makalaka, Makololo, Maganya (South Africa); Ova-Herero, Ova-Mho, Ganguella, A-Bunda, Ba-Fyot, A-Bongo, Ma-Yombe, Fan, Ba-Kale, Mpongwe, Ba-Koko, Dwalla, Bubi (western seaboard); Wa-Regga, Ba-Lolo, Tu-Shilonge, Ba-Ngala, Bu-Banghi, Ba-Teke, Ba-Lunda (Congo Basin).

The Oceanic division of the Ethiopic group comprises four branches: (1) The *Papuan*s of the Eastern Archipelago and New Guinea; (2) the closely allied *Melanesians* of the Solomon, New Hebrides, New Caledonia, Loyalty, and Fiji archipelagoes; (3) the now extinct *Tasmanians*; and (4) the *Australians*, the most divergent of all Negro or Negroid peoples.

Within both Ethiopic domains are scattered several dwarfish groups, the so-called *Negritos* or *Negrillos*—i.e. 'Little Negroes,' perhaps representing the true aboriginal element in these regions. In Africa the best known are the *Akkas* of the Upper Welle basin, the *Obongos* of the Gaboon, the *Batus* of the Middle Congo (smallest of men), and the *Bushmen* of South Africa, leading through the taller *Hottentots* to the Negroes proper. In Oceania still survive the *Aetas* of the Philippine Islands, the *Simungs* of the Malay Peninsula, the so-called *Mincopies* of the Andaman Islands, and the *Arfaks* of New Guinea. The *Kalungs* of Java have recently died out. Besides their smaller stature, all the Negritos differ from the Negroes by their extreme brachycephaly.

II. The MONGOLIC GROUP occupies the greater part of the eastern hemisphere, and till the discovery of America was in exclusive possession of the New World. Its chief branches are: (1) The *Mongolo-Tatars* of Central and North Asia, Asia Minor, parts of Russia and the Balkan Peninsula; (2) the *Tibeto-Indo-Chinese* of Tibet, China proper, Japan, and Indo-China; (3) the *Fimo-Ugrians* of Finland, Lapland, Esthonia, Middle Volga, Ural Mountains, North Siberia, Hungary (Magyars); (4) the *Malayo-Polynesians* of the Malay Peninsula, the greater and lesser Sunda Islands, Madagascar, the Philippines, Formosa, and Eastern Polynesia (New Zealand, Samoa, Tahiti, Hawaii, and Micronesia); (5) the *American Indians*, comprising all the aborigines of the New World except the *Esquimo*, who, with the *Ainos* of Yesso, form aberrant members of the Mongolic group.

III. The CAUCASIC GROUP, called also MEDITERRANEAN because its original domain is Western Asia, Europe, and North Africa—i.e. the lands encircling the Mediterranean Basin—has in recent times spread over the whole of the New World, South Africa, and Australasia. Chief branches: (1) *Aryans* of India, Iran, Armenia, Asia Minor, and great part of Europe, with sub-branches Hindus, Afghans, Persians, Beluchis, Armenians, Ossetians, Hellenes, Thracio-Illyrians, Italo-Siculi, Celts, Teutons, and Letto-Slavs; (2) *Semites* of Mesopotamia, Syria, Arabia, and North Africa, with sub-branches Assyrians (extinct), Syrians, Arabs, Phœnicians (extinct), Abyssinians, all except the last named now assimilated in speech to the Arabs; (3) *Hamites* of North and East Africa, with chief sub-branches Berbers of Mauritania, Tuaregs of West Sahara, Copts and Fellahin of

Egypt, Fulahs (?) of West Soudan, Bejas (Libbahi) and Afars (Danakil) along west side of the Red Sea, the mixed populations of Galla, Somali, and Kaffa Lands; (4) the *Caucasians* proper (Georgians, Circassians, Abkhassians, &c.); (5) the *Basques* of the Western Pyrenees, now distinguished mainly by their primitive speech from the surrounding Iberian and Gallic populations.

Although treatises on various branches of the anthropological sciences are past counting, comprehensive works of a strictly ethnological character are not numerous, and of these few can be recommended as safe guides to the student. The subjoined are valuable either intrinsically or as able expositions of particular theories: Blumenbach, *De Generis humani varietate nativa* (3d ed. 1795); Prichard, *Natural History of Man* (1843) and *Researches* (1813); Desmoulins, *Hist. Nat. des Races Humaines* (1826); Baer, *Vorlesungen über Anthropologie* (1824); Edwards, *Des Races Humaines* (1829); Bory de Saint-Vincent, *L'Homme* (2d ed. 1827); Courtet de l'Isle, *Tableau ethnographique* (1849); Thomas Smyth, *The Unity of the Human Race* (1851); Carl Vogt, *Lectures on Man*, &c. (English ed. undated); Holland, *De l'Homme* (1853); Cuvier, *L'Homme* (1857); Nott & Gliddon, *Types of Mankind* (1854) and *Indigenous Races of the Earth* (1854); Knox, *The Races of Men* (1862); D. Wilson, *Prehistoric Man* (1862); Latham, *Man and his Migrations* (1851); Nat. Hist. of the *Varieties of Man* (1850), and other ethnological essays; Waitz, *Anthropologie der Naturvölker* (1864); Müller, 'Ethnographie,' in *Reise der Novara* (1861 et seq.); Brace, *The Races of the Old World* (1863); Broca, *Le Linguistique et l'Anthropologie* (1862), &c.; Pouchet, *Plurality of the Human Races* (English ed. 1864); De Quatrefages, *Métamorphoses of Man* (English ed. 1864), &c.; Retzius, *Ethnologische Schriften* (1864); Rolfe, *Der Mensch* (1866); Bastian, *Das Beständige in den Menschennrassen* (1868), and many other treatises; Huxley, 'Man's Place in Nature,' in *Journal of Ethnol. Soc.* (1870); Hovelacque, *Langues, Races, Nationalités* (1872); Peschel, *The Races of Man* (1876); Topinard, *Anthropology* (English ed. 1878); C. Bray, *Manual of Anthropology* (1871); Tylor, *Anthropology* (1881); Joly, *Man before Metals* (1883); the publications of the Paris, British, and other Anthropological societies.

**Ethyl**, ( $C_2H_5$ ), is a colourless, inflammable gas, obtained by the action of iodide of ethyl,  $C_2H_5I$ , on granulated zinc. It possesses an agreeable odour, is insoluble in water, but soluble in alcohol. It is not, however, on its own account that ethyl is of importance, but because it is the starting-point of an important series of organic compounds known as the *ethyl series*. In all of these the group  $CH_3-CH_2$  or  $C_2H_5$  is present, and acts as if it were an atom of some elementary substance—e.g. potassium. Thus we have

Potassium,	K;	Ethyl,	$C_2H_5$
A molecule of Potassium,	$K_2$ ;	A molecule of Ethyl,	$(C_2H_5)_2$
Potassium Iodide,	$KI$ ;	Ethyl Iodide,	$C_2H_5I$
Potassium Oxide,	$K_2O$ ;	Ethyl Oxide or Ether	$(C_2H_5)_2O$
Caustic Potash,	$KOH$ ;	Ethyl Hydrate or Alcohol,	$C_2H_5OH$

In these we see that the group of atoms,  $C_2H_5$ , always enters into combination as if it were indivisible, and it is usual to call this group ethyl, and to reserve the term diethyl for the compound  $(C_2H_5)_2$  described above. Ethyl,  $C_2H_5$ , is only hypothetical, and does not exist in the free state, while diethyl,  $(C_2H_5)_2$ , is an actual gas. See ALCOHOL, BASE, and ETHER.

**Ethylamine**,  $NH_2C_2H_5$ , is a substance resembling ordinary ammonia in its odour and many of its properties. It is found in coal-tar, in the oil obtained during the destructive distillation of bones, in the gases evolved during putrefaction, and may be produced by complicated chemical processes. Ethylamine has been called an artificial alkaloid (see ALKALOID), because it is regarded from a chemical point of view as ammonia, in which one atom of hydrogen is replaced by the group Ethyl (q.v.).

**Etiolation.** See BLANCHING.

**Etive**, a salmon-river and a sea-loch of Argyllshire. The river, issuing from a loch on Rannoch Muir, near lonely Kingshouse Inn, runs 15 miles south-westward to the head of the loch, which itself extends 10½ miles south-westward, then 8½ westward, until at Dunstaffnage Castle, 3½ miles NNE. of Oban, it merges in the Firth of Lorne. Narrowing from 1½ mile to less than 2 furlongs at Connel Ferry, its reef-barred entrance, where the depth too decreases from 420 feet to 6 at low-water, this loch offers a good example of an ancient submerged glen. Like that of Loch Awe (q.v.), its scenery is magnificent, the upper reach closely engirt by mountains, of which the loftiest are Ben Ciachan (3689 feet) and Ben Starav (3541). Aichattan Priory, founded on its north shore in 1281 for monks of the order of Vallis Caulium, is a beautiful ruin; so, too, is Dunstaffnage, the fabled seat of the Dalriadan kings, the stronghold really of Macdougals and Campbells, and the prison for a while of Flora Macdonald. See also BEREGONIUM.

**Etna**, or *Ætna* (called by the modern Sicilians MONTE GIBELLO—the last part of the name being the Arabic *Jebel* Italianised), an isolated volcanic mountain close to the east coast of Sicily, with a base 90 miles in circumference, and a height of 10,850 feet. The mountain mass rises with gentle and regular slopes up to a single cone, containing the crater, a chasm about 1000 feet in depth and from 2 to 3 miles in circumference. The regularity of the slope is, however, broken by the Val del Bove, an immense gully excavating the eastern flank of the mountain, 4 or 5 miles in diameter, and surrounded by nearly vertical precipices from 2000 to 4000 feet high; it has a singularly dreary and blasted appearance. A striking feature is the very great number of secondary cones dotted all over the flanks of the mountain. Of these the principal are the Monti Rossi, 450 feet high, twin peaks which were cast up during the eruption of 1669. The slopes of the mountain are divided into three sharply defined zones, the cultivated, the woody, and the desert region. This last, extending from about 6300 feet upwards, is a dreary waste of black lava, scoria, ashes, and sand, covered during the greater part of the year with a sheet of snow. The wooded region, which stretches down to the line of 2000 feet, though with considerable variation of breadth, is planted with forests of chestnuts, beeches, birches, pines, maples, and oaks. Below this lies the cultivated zone, a thickly peopled region of great fertility, where the vine, date-palm, bananas, sugar-cane, oranges, lemons, olives, figs, almonds, &c. are grown. The ascent is usually made from Catania, a town on the coast to the south. The origin of the mountain goes back to the Pliocene age, when its foundation was probably begun in a submarine bay penetrating into the west coast of Sicily. The geological structure of the Val del Bove lends support to the view that there once existed a second great crater, the centre of permanent eruption.

The most remarkable of the recorded eruptions of Etna are the following: 1169, when Catania and 15,000 of its inhabitants were destroyed; 1329, when a new crater opened near the Val del Bove; 1444, when the cone fell into the crater; 1537, on which occasion two villages and many human beings perished; from 1603 to 1620 Etna was almost continually in activity; in 1666 three new craters were formed. The most violent outburst of all was, however, that of 1669, when a chasm 12 miles long opened in the flank of the mountain, and from it issued a line of flames, whilst a new crater was made. During an outburst in 1755 a large flood of water was poured down from the Val del Bove. In 1852–53 there was a violent eruption which lasted nine months; a

torrent of lava, 6 miles long by 2 broad, and some 12 feet in depth, was ejected. About 100 eruptions have been pretty accurately described, 16 having occurred in the 19th century. In 1880 an observatory was built on the south side of the mountain, at a height of 9075 feet above the sea, being the highest inhabited house in Europe (nearly 1000 feet higher than the hospice of the Great St Bernard). See Ferrara, *Descrizione dell' Etna* (1818); Rodwell, *Etna and its Eruptions* (1878); and Sartorius von Waltershausen, *Der Aetna*, edited by Von Lasaulx (2 vols. Leip. 1880).

**Eton**, a town in the south of Buckinghamshire, on the left bank of the Thames, 21 miles WSW. of London. It lies opposite to Windsor, in Berkshire, and is included in its parliamentary borough. Eton chiefly consists of one long street, and is mainly dependent on the college. Pop. (1881) 3464; (1891) 2499, at which date the school had first reached the number of 1000 pupils.

ETON COLLEGE, one among the most famous educational establishments in England, was founded in 1440 by Henry VI., under the title of 'The College of the Blessed Mary of Eton beside Windsor.' The original foundation consisted of a provost, 10 priests, 4 clerks, 6 choristers, 25 poor grammar-scholars, a master, and 25 poor infirm men. The king provided for the establishment out of his own demesne lands and the estates of certain alien priories. A supplementary charter was granted in 1441, in which year also the college buildings were commenced. Henry was very solicitous that the work should be of a durable kind. Some of the buildings were finished in 1443, and were handed over by the royal commissioners to the provost, clerk, and scholars. Political troubles of various kinds retarded the completion of the buildings till 1523. Bishop Waynflete was the first head-master, and afterwards a munificent supporter of the college. The institution passed through much peril in the reign of Edward IV., and again in the time of the Commonwealth; but it weathered the dangers, and the increasing value of its estates brought in a large income. The original foundation has been greatly modified under the Public Schools Act, 1868. It now consists of a provost and 10 fellows, who constitute the 'governing body,' 2 chaplains or conductors, and 70 king's scholars or collegers. The members of the governing body are nominated by the universities of Oxford and Cambridge and other learned and responsible electors. Several valuable scholarships at King's College, Cambridge, are filled up every year from among the scholars or oppidians by competitive examination. There are also other scholarships and prizes open to all the members of the school, such as the Newcastle and Tomline scholarships, and prizes for modern languages, founded by the late Prince Consort. The scholars are lodged within the college walls. The main portion of the establishment, however, numbering nearly 900, consists of the *oppidians*, students who live in houses held by the masters, and whose friends pay liberally for their education. The tuition is the same for them as for the collegers. Till 1851 the course of education was purely classical, but mathematics was admitted into the curriculum in that year, physical science in 1869, and the college now possesses an admirable museum, laboratory, and observatory. Among famous Etonians have been Bolingbroke, Boyle, Canning, Chatham, Derby, Fielding, Fox, Gladstone, Gray, Hallam, Kinglake, Lyttelton, Milman, Porson, Praed, Pusey, Shelley, the Walpoles, Wellesley, and Wellington.

The college buildings are of various date and varying beauty—from the original work of the 'royal saint' down to a chapel for the younger

boys, a museum, and other school buildings, whose memorial stone was laid by Queen Victoria on 18th May 1889. They include the chapel, hall, library, and schools, the provost's and master's apartments, and the lodgings of the fellows, surrounding two quadrangles. The chapel is of stone, the other buildings of brick; and the effect of the whole is strikingly picturesque, as seen from the terrace of Windsor Castle, on the other side of the Thames. The Gothic chapel is especially beautiful, rich in carving and painted glass. The 'Montem,' or triennial procession to Salt Hill (*ad montem*), was celebrated last in 1846. See Maxwell Lyte's *History of Eton College* (1875; new ed. 1889); Creasy's *Eminent Etonians* (1850; new ed. 1876); and Jesse's *Celebrated Etonians* (1875).

**Etretat**, a Norman watering-place, 18 miles N.E. of Havre, in a country remarkable for picturesque rock formations. Pop. 2000.

**Etruria** was the country inhabited or ruled by the Etruscans, a very ancient people of Italy. Etruria Propria, with which we are chiefly concerned, lay west of the Tiber and the Apennines, and included the valley of the Arno. In the 6th and 5th centuries B.C. the Etruscans held also the valley of the Po, called Etruria Cispadana, and a region south of the Tiber, called Etruria Campaniana. Etruria Propria was a confederation of twelve cities or states, the *duodecim populi Etrurie*. No list of those cities has come down to us, but Veii, Tarquinii, Cære, Clusium, Cortona, Perugia, Vulci, Volsinii, Vetulonia, Volaterra, and Aretium may probably be included, while the twelfth may have been either Rusellæ, Falerii, or Populonia. To the northern confederation twelve cities are also assigned; among them we may reckon Mantua, Chiavenna, Felsina (Bologna), Ravenna, and Hatria, whose importance is shown

deserted sites, marked only by vast cemeteries and the remains of cyclopean walls, while others still retain more or less of their old importance.

Veii, for four centuries the formidable foe and rival of Rome, from which it is only 11 miles distant, is now utterly desolate. It was taken and destroyed by Camillus in 396 B.C. The necropolis, extending over 16 sq. m., attests the splendour of the ancient city and the vast population which must have dwelt within its walls, 7 miles in circuit. Six miles from the sea, midway between

Fig. 1.

Rome and Civita Vecchia, is the village of Cervetri, which preserves the name and marks the site of Cære, which, under its older name of Agrylla, is said to have been a 'Pelasgian' city before the arrival of the Etruscans. On this site inscriptions have been found, written in a language and an alphabet called 'Pelagic,' and believed to be pre-Etruscan. The paintings in some of the tombs are in a style no less archaic. Of later date is the tomb of the Tarquins, who are said to have fled to Cære when expelled from Rome. Cortona, perched upon a rock, and surrounded by fragments of massive walls, possibly of pre-Etruscan date, occupies the most venerable site in Italy. In the time of Herodotus, Cortona, like Cære, retained its 'Pelagic' character. Dionysius says it was a great and flourishing city of the Umbrians before it was taken by the Etruscans, who made it their northern capital. The bronze-workers of Cortona were renowned, and the local museum contains noteworthy examples of their skill. The southern capital was Tarquinii, a city purely Etruscan. Corneto, a town 60 miles from Rome, and not far from the sea, occupies a portion of the site. The necropolis of Tarquinii, which extends over many miles, contains several sepulchral chambers, painted in the archaic style of the genuine art of the Etruscans, and giving a curious insight into their religious beliefs. We have scenes from the under-world, representing souls riding on horseback or seated in cars, led away in the charge of good or evil spirits. Elsewhere the daily life of the people is depicted; we see horsemen returning from the chase, chariots, bear-hunts, wrestlers, pugilists, banqueting scenes, dancing girls, and musicians. Fig. 1 represents a dancing girl and musicians from the walls of a tomb called the Grotta del Trincino, and fig. 2 a death-scene from a tomb called the Camera del Morte. The tombs of Clusium (now Chiusi) exhibit the same archaic character as those of Tarquinii. A vast chambered tumulus called the Poggio Gajella is probably that described by Varro as the tomb of Laus Porsena. Vulci, though barely mentioned by historians, must have been a very wealthy and populous city. The necropolis has yielded a richer treasure of artistic objects than any other Etruscan site. The Cucumella, a huge chambered tumulus like that at Clusium, bears a curious resemblance to the great tomb of Alyattes,

by its having given a name to the Adriatic. In the southern province were Capua and Nola, and possibly Salerno. Some of these cities are now

king of Lydia, the father of Croesus, near Sardis. Volsinii gave its name to Lake Bolsena, on whose shores it stood. It was one of the most powerful Etruscan cities, and one of the last to yield to Rome. From Volsinii we have few monuments or inscriptions, the necropolis not having yet been found. On the other hand, Perugia (now Perugia) has yielded 1200 inscriptions, among them the famous cippus, a stone containing the only Etruscan inscription of considerable length. It has not been deciphered, but appears to be the record of the assignment of a sepulchre to the Velthina family.

Fig. 2.

Velathri (now Volterra), called Volaterra by the Romans, stands, like Cortona, upon an almost impregnable rock, surrounded by Etruscan walls, five miles in circuit. It held out against the Romans after all the rest of Etruria had been subdued. The people burned their dead instead of burying them, and the local museum contains 400 ash-chests, like miniature sarcophagi, the sides carved with mythological subjects, or with representations of bull-fights, boar-hunts, horse-races, and gladiatorial combats. Cyclopean walls mark the sites of Rusellæ, Cosa, Saturnia, and of Pupluna (Populonia), a seaport, interesting chiefly for its coins. The walls of Fiesole (Biesole), near Florence, are well known to travellers. Orvieto (*Urbs Vetus*) must have been an important Etruscan site, but its ancient name is unknown. Vetulonia was probably near Magliano, a squalid village in the Maremma. Neither Luna nor Pise have yielded any remains of interest. Other Etruscan sites, among them Viterbo (Sutrin), Bologna (Felsina), Toscanella (Tuscania), Siena (Senæ), Arezzo (Arretium), Sovana (Sutana), and Farento (Feren-tium), are described by Dennis, *Cities and Cemeteries of Etruria* (2d ed. 1878), to which the reader may be referred for fuller information.

*History.*—The history of Etruria, like that of Carthage, has to be reconstructed from accounts transmitted by hereditary fœces. The Roman legends represent Etruria as a powerful and wealthy state before Rome was founded. According to a tradition preserved by Varro, the Etruscan era commenced in 1044 B.C., nearly three centuries before that of Rome. When legend ceases and history begins, we find the Etruscans a great naval power, allied with Carthage against the Greeks, and dominant throughout northern and central Italy, Rome itself being included in the Etruscan dominion, and ruled by Etruscan kings. The legend of the migration of the Tarquin dynasty from Tarquinii may signify the extension of the domination of that powerful city over the regions southward of the Tiber. A cemetery, believed to be Etruscan, has been discovered on the Esquiline, and the Celian Hill in Rome bears the name of the Etruscan chieftain Cæles Vibenna. The paintings and inscriptions in a tomb at Vulci give an Etruscan version of the Tarquinian story. We see the hero 'Maestrna' (Mastarna), an

Etruscan appellation applied to Servius Tullius, cutting the bonds of his friend and companion Cæle Vibinas (Cæles Vibenna), while Cneve Tarhminies Ramach (Cn. Tarquinius Romanus) is being killed by an Etruscan. The names of Tarquin, Mastarna, and Cæles Vibenna, thus curiously preserved, prove that Livy's account of the Etruscan kings of Rome is not wholly legendary. But that it was not derived from contemporary sources is indicated by a recent discovery of considerable interest. We learn that in 509 B.C. Lars Porsena of Clusium, as Livy calls him, marched with a great army to the gates of Rome to replace Tarquin on the throne. Now, in a newly-opened tomb at Vulci, a sarcophagus was found, on which is depicted in relief a high official with insignia resembling those of a Roman consul. He is riding in procession on a biga, preceded by two lictors with their fasces, and followed by two servants. The inscription informs us that this deceased magistrate, Tuto Larth, was *pursvama thus*, 'five times Porsena.' It is manifest that Porsena was not, as Livy supposed, a proper name, but, like 'Pharaoh' in Egypt, the designation of an office; and that the Etruscan chief who took up Tarquin's cause was the elected 'Porsena' or chief-magistrate of Clusium. In like manner, since the word *machs* meant 'first' in Etruscan, it seems probable that Maestrna, the Etruscan appellation of Servius Tullius, was not a proper name, but a designation of the kingly office, equivalent, it would seem, to Princeps. We are also told that Tarquin, with his two sons, Titus and Aruns, took refuge in Carre. Not only are Tite and Arnth usual names in Etruscan epitaphs, but at Cervetri, the site of Carre, there is an immense chambered tomb containing mortuary records of forty-six members of the Tarca family, which must have been resident at Carre for many generations.

As an Etruscan city, Rome plainly attained a greater height of prosperity than she regained for two centuries. This is indicated not only by the legends of the splendour of the Tarquinian kings, but by the evidence of such vast constructions as the Cloaca Maxima, the Capitoline temple, and the Servian wall. The stato ceremonial of Rome appears also to have descended from the period of Etruscan rule. The insignia of consular authority, the toga prætexta with its purple border, the ivory curule chair, the twelve lictors with their fasces and axes, all of Etruscan origin, are not likely to have been copied from the usages of hereditary fœces, but are more probably survivals from the period when Rome was one of the Etruscan cities. An Etruscan origin may also be assigned to the circens, the gladiatorial combats, the horse-races, the triumphal processions, the pipe-players, the litæns, the colleges of augurs, as well as the arrangement of the house, the art of constructing aqueducts and sewers, the division of the *as* into twelve parts, the beginnings of military science, and some of the Roman weapons. More than all, the high position of the wife, so different from that which she occupied in Greece, was the same as that which she occupied in Etruria.

How feeble was the Roman republic in its infancy appears from the fact that for a century after the expulsion of her Etruscan lords Rome maintained 'with varying fortunes the struggle with the Etruscan town of Veii, distant 11 miles only from her gates. That Veii fully held her own is shown by the admission that in the year 476 B.C. she captured the Janiculum. At that time the Etruscans were still the greatest military power in Italy. At the height of their prosperity, in the 6th century B.C., they shared with the Phœnicians and the Greeks the maritime supremacy of the Mediter-

anean. In 538 B.C., in conjunction with the Carthaginians, they sent a powerful fleet to expel the Greek colonists from Corsica. They attacked the Greek colony of Cumæ in 525 B.C., and again in 474 B.C., when their naval power was shattered by Hiero I. of Syracuse, in a great battle fought off Cumæ, the first event in Etruscan history as to which we possess contemporary records. The victory was celebrated by an ode of Pindar, then resident at the court of Hiero; while from the inscription on a bronze helmet, found at Olympia in 1817, and now in the British Museum, we learn that it was an Etruscan trophy from Cumæ, dedicated by Hiero and the Syracusans to the Olympian Zeus. In 453 B.C. we find the Etruscans still in possession of Corsica, and in 414 they were able to send a contingent of three ships to aid the Athenians at the siege of Syracuse.

But from this time dates the rapid declension of their power. Towards the close of this century the Etruscan dominion in Campania was overthrown by the Samnites and the Greeks of Cumæ, Capua being taken by the Samnites in 423. Then the Gauls swarmed over the Alps, and, after overwhelming the Etruscan cities in the valley of the Po, crossed the Apennines, having destroyed the wealthy city of Melipum in 396 B.C., the year in which the long struggle between Rome and Veii was brought to an end by the capture of the latter by Camillus, after a ten years' siege. The Gauls continued their devastating progress through Etruria, and in 390 plundered Rome, after having vainly laid siege to Clusium. Etruria was fatally weakened by the loss of her two outlying provinces and the devastation of the central province by the Gauls. After a prolonged resistance, southern Etruria submitted to Rome in 331 B.C. In 311 war was renewed; the Romans crossed the natural boundary formed by the Ciminian Forest, and, after repeated defeats of the Etruscans, a decisive contest took place in 283 at the Vadimonian Lake, when Tarquinii lost its independence; and three years later the Romans reached Volaterra, the northern stronghold of the Etruscans, when the struggle, which had endured for five centuries, came finally to an end.

In the Second Punic War, the chief Etruscan cities furnished supplies for the Roman fleet. It is plain that these cities retained wealth and power as semi-independent allies under the Roman suzerainty. They seem to have been gradually Romanised, and were finally admitted to the Roman franchise in 89 B.C. The great Etruscan families secured leading positions in the Roman commonwealth. Pompey the Great seems to have been of Etruscan lineage, tombs of the Pompeii family having been discovered at Corneto (Tarquinii), Clusium, Cortona, and Perugia. There was a Tarquinian gens at Rome in the time of Cicero, while Mæcenas, who bears an Etruscan name, was from the Etruscan city of Arretium (Arezzo). Families of undoubted Etruscan lineage still linger on in Etruria. The necropolis at Volterra contains the tomb, with Etruscan epitaphs, of the Ceina (Cæcina) family, members of which distinguished themselves under the early emperors, and whose lineal representative, Nicolas Cæcina, bishop and patrician, was buried in the cathedral of Volterra in 1765.

*Origin.*—The people of Etruria were called Etrusci or Tursi by the Romans, Tyrrheni or Tyrseni by the Greeks, Tursci by the Umbrians, and Rasena by themselves. Their origin and ethnic affinities have been much discussed. An early tradition, reported by Herodotus, and repeated by twenty-two ancient writers, brings them from Lydia; but Dionysius of Halicarnassus doubts any such migration, because it is not mentioned in the Lydian history of Xanthus, and

because the Etruscans differed from the Lydians in language, laws, customs, and religion. Dionysius adds that the Etruscans were a very ancient people, unlike all others in speech and manners.

Modern writers who accept the Lydian tradition point out that Tarquinii, probably the mother-city of the Etruscans, is near the coast, and appeal to striking structural resemblances between tombs at Vulci, Clusium, and Tarquinii, and certain tombs near Sardis. They argue that, if Phœacians settled in Corsica, Lydians may have found their way to Italy, and that, if the Etruscans had entered Italy by the Rætian Alps, the oldest settlements would be found in the valley of the Po, and not between the Arno and the Tiber. But it must be acknowledged that the migration of so numerous a people by sea is a formidable difficulty. In modern times it has been maintained that their language was Semitic, Celtic, Armenian, Gothic, Basque, or Albanian. Professor Sayce thinks it is *sui generis*, belonging to a family of speech which has everywhere become extinct. The present writer believes that the affinities are Ugro-Altaic, and of late years this opinion has gained ground. The failure of Coissen's attempt to explain the language as an Aryan dialect, akin to Umbrian, Oscan, and Latin, is a gain in the negative direction, and few scholars would now be found to maintain that it belongs either to the Aryan or Semitic families of speech. It seems rather to have been an agglutinative dialect, approximating, like the Finnish, to the inflectional stage.

Mommsen thinks the Lydian tradition arose from a confusion between the Torrhebi of Lydia and the Tyrrheni of Italy. Fresh light has been thrown on the question by the recent discovery in Lemnos of two inscriptions in a language which, if not Etruscan, resembles it in many points. Theophrastus says that Lemnos was inhabited by Tyrrhenians, and Dr Pauli thinks these inscriptions prove that the Tyrrhenians (Etruscans) of Italy belonged to a non-Aryan Tyrrhenian race, which also occupied portions of the Aegean coasts.

Probably there were two elements in the population of Etruria, one autochthonous, numerous, and servile; the other an intrusive conquering aristocracy. Cære and Cortona are said to have been 'Pelagic' cities before they were occupied by the Etruscans. Certain inscriptions from Etrurian tombs, formerly classed as Etruscan, are now attributed to the more ancient 'Pelagic' race. Conestabile distinguishes between the tombs of an aboriginal people who practised cremation and those of the later invaders who buried their dead. Livy says that the speech of the country-folk in Etruria differed from the language spoken in the towns, and we may well believe that a conquered race would be left to till the soil for the benefit of invaders dwelling in walled towns. The splendid tombs from which our knowledge of Etruscan speech, luxury, and art is derived cluster round the walls of a few great cities, and are mostly the sepulchres of wealthy nobles. We occasionally meet with the urn of a freedman (*lautus*) or of a slave, but we know nothing of the tombs of the inhabitants of the villages, who may well have belonged to another race, and have spoken a different language. Again, the abrupt collapse of the Etruscan dominion in Campania and in the valley of the Po indicates that it was a dominion of conquest rather than of colonisation; and the complete effacement of the language in Etruria proper argues that the Rasena were a ruling aristocracy, comparatively few in number, though high in culture.

The physical type of the Etruscans is decidedly not Aryan. Professor Calori affirms that Etruscan skulls differ markedly in shape from all other Italic

skills. The descriptions by ancient authors, '*pinguis Etruscus*,' '*obesus Pyrrhenus*,' are confirmed by the recumbent portrait effigies on the sarcophagi, which show they were a sturdy race, short and stout, with large heads, thick arms, high colour, scanty beard, and hair black or occasionally chestnut. It has been remarked that they were not unlike the Kheta (Hittites) who invaded Syria from the north, and whose monuments are found in Asia Minor as far west as the neighbourhood of Sardis. In any case we may agree with Dionysius that the language, customs, and religion of the Etruscans differed from those of any nation with which he could have been acquainted, while their physical type, as represented on their monuments, is so unlike that of other Europeans as to incline us to agree with the dictum of Seneca: *Tuscos Asia sibi vindicat*—Asia claims the Etruscans as her own.

*Language.*—The Etruscans had an extensive literature. The subjects represented on the monuments prove their familiarity with the tale of Troy and the cycle of Greek heroic legend, and we learn that they possessed histories, poems, dramas, and works on augury and divination. But their books have perished, so that in addition to a few doubtful Etruscan words preserved by Hesychius, Varro, and other writers, our knowledge of the language is derived only from inscriptions, of which about 5000 have been discovered. To the meaning of these we have unfortunately no clue, as the few bilinguals consist mainly of proper names. They wrote from right to left, in an archaic form of the Italic alphabet, which was obtained from Eubœa about the 7th century B.C. The Etruscan alphabet differs from the Latin in retaining the letters *theta*, *phi*, *chi*, and *san*, and in rejecting *d*, *b*, *g*, and *o*.

Most of the inscriptions are very short, only five containing more than twenty words. The longest, that on the Perugia cippus, extends to forty-six lines. They have been found as far north as the Alps, near Nice, Turin, and the lakes of Como and Lugano. But they mostly come from five or six sites in Central Etruria, one-fourth of the whole number being from Chiusi, and one-third from Perugia. Some vast cemeteries, such as those of Veii and Bologna, have yielded few or none, possibly because they date from a time when the art of writing had not become general.

About 4000 of the inscriptions are short mortuary records, stating usually the name and parentage of the deceased; his age, his condition in life, and the public offices he held being occasionally added. They occur on the walls or over the entrances of vaults, on steles or pillars erected in front of tombs, or on the labels and seals of sepulchral niches, but they are more usually painted on the urns, or cut in the stone of the sarcophagi, a recumbent figure of the deceased frequently reposing on the lid, while the sides are sculptured with mythological subjects or scenes from the life of the deceased.

Working with such materials, German and English scholars have recently made considerable progress in the decipherment of the language, so that most of the short mortuary inscriptions can now be read with tolerable certainty. The inscriptions contain some 200 Etruscan words in addition to the proper names. Of these names a few, such as Cate (Gaius), Cneve (Gnaeus), Marce (Marcus), and Tite (Titus), are borrowed from neighbouring or subject races. Of genuine Etruscan names the most usual for men are Arnth (Aruns), Aulo (Aulus), Larth (Lars), Sethre, Vole, Velthur, and Vete; and for women, Arnthia, Aulia, Larthia, Sethria, Pastia, Ranthia, Thania, and Thanevil. Many Roman gentile names, such as Spurinna and

Perpenna, were of Etruscan origin, while Pompeius, Paternus, Catulus, Cassius, Cicerus, Volturnus,

~~~~~  
Afina. A few Etruscan names have been explained. Thus, Thanevil (Tanaquil) was the wife of Tarquinius Priscus. Thana must have been the Etruscan goddess of maternity (= Juno Lucina), as on a mirror she assists at the birth of Minerva, and *evil* (or *ever*) denotes 'gift' or 'dedication,' the word Tuscevil being inscribed on objects dedicated to Tina (Jupiter). Hence Thanevil would mean 'Thana's gift,' and may be compared with such Christian names as Theodore or Diodorus. Again, Spurio, an Etruscan name, seems to be equivalent to the Latin Publius. The words *spural* and *spurana*, inscribed on vessels, armour, and tombs, signify that they were 'civic' or 'public' property; and the phrase *ance marunuch spurana*, in an epitaph, probably means '*uit curator publicus*.'

Relationship is sometimes expressed by words, such as *puia*, 'wife'; *clan*, 'son'; *ser*, 'daughter'; but more commonly by suffixes. Thus, Aulesa is the 'wife of Aule,' Thepria the 'wife of the Thepri' (Tiberius), Larthia the 'son of Larthia,' Larthialisa the 'wife of Larthia's son.' Velthur is a 'descendant of Vele,' and Volthurithura a 'descendant of Velthur.' Gentile names are formed by the suffix *-na*, corresponding to the Latin *-ius*. Thus, Vipna is the equivalent of Vibius, Varna of Varius, Caisna of Cæsius. This suffix is a common formative. Thus *suthi*, '*sepulcrum*,' gives *suthina*, '*sepulchralis*.' The suffix *-l* or *-al* has a similar force—e.g. *futhsul*, 'a Bacchic cup,' from *futhsul*, 'Bacchus'; and *Truiul*, 'a Trojan,' from *Trui*, 'Troy.' Other ethnic formatives are *-ach* and *-ete*, as *Lenmach*, 'a Roman,' and *Manthvate*, 'a Mantuan.'

Six words inscribed on the faces of a pair of dice give the first six digits, and other numerals appear in records of age which occur in epitaphs. The words *mach*, *ci*, *zul*, *su*, *thu*, *huth*, *semph*, *ecsp*, *muu* are believed to be the digits, while *co-alehi*, *ecsp-alehi*, *semph-alehi*, *muu-alehi*, *zathrum*, and *cien-zathrum* must be decades. Ordinals and multiples are formed from the cardinals. Thus *ci*, 'two,' gives *ci-s*, 'second,' and *ci-si*, 'twice.'

The detection of the numerals has made it possible to show that the plural ends in *r* or *l*. Thus, *clan*, 'son,' gives *clen-ar*, 'sons'; as *ci clen-ar*, 'two sons,' and *clen-ar zul*, 'three sons.' The phrases *huth naper*, *naper ci*, *naper zil*, show that *naper* is a plural, meaning '*loculi*' or 'tombs.' The plural in *-l* also appears in *avec zil levil*, '*habuit annos levil*,' and in *muuul ar*. So *tular* signifies 'cippi,' and *suthinesl* 'sepulchral niches.'

The names of men and women already cited, and such forms as *laulni*, 'a freedman,' and *laulnitha*, 'a freed-woman,' show that Etruscan was a gender language. There seems to have been no distinction between nominative and accusative. The genitive ended in *-s*, the dative in *-si* or *-thi*; and, as in the Italic languages, the plural suffix preceded that denoting the case. Thus, from *clan*, 'son,' we have gen. *clen-s*, dat. *clen-si*, nom. and acc. pl. *clen-ar*, dat. pl. *clen-ar-asi*; while *preuth-ar-asi* is the dat. pl. of *preus*. From *tiv*, 'moon' or 'month,' we have *tiv-r*, '*mensis*,' and *tiv-r-s*, '*mensium*,' from *usil*, '*sol*,' *usil-s*, '*solis*,' and from *suthi*, '*sepulcrum*,' *suthi-thi*, '*sepulchro*.' The suffixes *-c* and *-m* are enclitic conjunctions—thus, *vel. sethre puia* is the epitaph of 'Volo Sethre and wife,' and *arnth vipis sorturi puia* multiplies that of 'Arnth (son of) Vipi Sorturi and (his) wife Mutainoi.' According to Dr Pauli, *ni* means 'this,' or 'this is,' while *cehen*, *cen*, or *cen* means 'here.' The meaning of several substantives, in addition to those already cited, has also been determined with tolerable certainty.

Coming to the verbs, *an-cc* certainly means 'fuit,' while *ma* appears to be 'est.' The 3d pers. sing. of the perfect tense ended in *-ce*, and of the present in *-e*. We have *tur-e*, 'dat'; *tur-ce*, 'dedit'; *ar-ce*, 'habuit'; *tham-ce*, 'extruxit'; *sval-ce*, 'obiit'; *lupn-ce*, 'decessit.' Thus, *clenar zal arce* is 'filios tres habuit,' and *ramtha matulnei sech marces matulnas putiam amce sethres coisines* may be translated 'Ramtha Matulnei was the daughter of Marce Metulna, and wife of Sethre Ceisinie. These examples may serve to show that the once apparently hopeless task of translating the Etruscan inscriptions is at last in a fair way of being accomplished.

**Religion.**—The Etruscans were proverbially a religious people—'*gens ante omnes dedita religionibus*,'—'*genitrix et mater superstitionis Etruria*.' Their tombs bear witness to a belief in a future life, and a dread of the malignant power of their deities. Affairs of state were regulated by the decisions of colleges of haruspices and augurs, who interpreted, according to established rules, omens and portents obtained from the inspection of the entrails of victims, the flight of birds, and from lightning, of which twelve kinds were distinguished. Varro, Cicero, and Martianus Capella have described the methods of divination, as laid down in the *libri disciplina Etrusca*. The heavens were regarded as the *templum* of the gods, and were divided into sixteen regions, in each of which one or more of the gods presided or resided. By ascertaining the precise 'region' in which an omen, such as a flash of lightning, occurred, the fulgurators determined the name of the god who sent the message, and interpreted it in accordance with his functions. Those gods who possessed the power of sending lightning were called the *Novensiles*, or 'Thunderers.' In the museum at Volterra is an effigy of an augur, holding in his hand the instrument by which these observations were made, and an actual specimen of the instrument has recently been discovered near Piacenza. It is a bronze model of the liver of a calf, which must have been used like a sextant. Beginning with the north, the rim is divided into sixteen compartments, in each of which the name of one of the gods is engraved. The heavens were observed through apertures which correspond to the blood-vessels which supply the liver. One side of the instrument is dedicated to the sun, the other to the moon, probably for observations by day or by night. The protuberance called the *lobus Spigelii* was the 'mount of the gods,' and the gall-bladder was dedicated to Neptune. The names of the deities inscribed on this curious instrument, coupled with the account of Martianus Capella, have supplied unexpected information as to the Etruscan Pantheon, and this is supplemented by the names appended to the deities in the mythological subjects painted on the walls of tombs, or engraved on the backs of the polished bronze mirrors

used by Etruscan ladies, of which four hundred are known. In many cases the subjects are taken from the Greek mythology, and the names are merely those of Hellenic or Italic deities, conformed to the phonetic laws of Etruscan spelling. Such are Ani (Janus), Uni (Juno), Maris (Mars), Apulu (Apollo), Nethluns (Neptune), Ercele (Hercules), Menrva (Minerva), Velch (Vulcan), Satre (Saturnus), Artumes (Artemis), Letun (Latona), Vetis (Vedius), Silvans (Silvanus), Aita (Hades), Pherisipnei (Persephone), and Charu (Charon). But besides these borrowed names there are a host of genuine Etruscan deities, such as Tinia, who answers to Jupiter, Laran to Mars, Fufluns to Bacchus, Sethlans to Vulcan, Turan to Venus, Turms to Mercury, Thalna to Juno, Thana to Lucina, Thesan to Aurora, while the sun and the

Fig. 3.—Etruscan Mirror from Vulci, with Fufuns (Bacchus), Semele (Semele), and Apulu (Apollo).

Half size. After a Drawing by Mr George Scharf.

moon were called Usil and Lala. Of other deities no analogues have been found in the Greek or Roman Pantheon. Lasa and Mean seem to be recording Fates; Epiur, Snenath, Munthuch, and Malavisch to be guardian spirits; Tuchulcha, Asira, Nathum, and Taisu avenging Furies; Vantl, Leintl, and Culsu conductors of souls or deities of the tomb. More obscure are the functions of beings called Racuneta, Talitha, Tethuni, Thrufla, Mlacnch, Achuvitr, Tipanu, Sitnica, and Ethausva. If anything were wanted to prove that the Etruscan mythology differed from that of all Aryan, Semitic, and Hamitic nations, this strange list of names would be sufficient. Classical writers have assigned to the Etruscans other deities whose names are not found in inscriptions, and which may be Sabine, Umbrian, or Faliscan. Among them may be enumerated Mantus and Mania, king and queen

of the under-world; Summanus, a god who ruled the night; Veitumnus, the god of autumn; Voltunna, whose temple was the meeting-place of the federated states; Nortia, the goddess of Fortune, in the doors of whose temple at Volturni nails were driven to mark the successive years; and the Novensiles, a collective name for those gods who hurled thunderbolts.

*Civilisation.*—The government was a loose federal union of the twelve cities or states, each ruled by magistrates annually elected from a class of hereditary sacerdotal nobles. The titles of these magistrates, *Lauchme* (Lucumo), *Purtavana* (Poisena), and *Marunuch*, probably correspond to Consul, Imperator, and Curator. The position of the wife was high; she is the social equal of the husband, she takes her place at the feast, her tomb is sumptuously furnished, and descent through the mother is recorded even more uniformly than through the father. The reliefs on the *Afuna sarcophagus* at Palermo, in which a matron bids farewell to her sorrowing family, afford a touching proof of the affection with which the wife and mother was regarded. Of the high civilisation attained by the Etruscans we have abundant proofs. Till the battle of Cumæ they were one of the three great naval powers of the Mediterranean. They excelled in medicine, astronomy, mining, metallurgy, and such engineering works as the construction of roads, tunnels, and chambered tombs. The walls of their cities, built of huge blocks, admirably fitted together without cement, remain to attest the skill of the artificers. The jewelry, of the Phœnician type, with patterns formed by soldering on minute grains of gold, is unrivalled. The skill of the bronze-workers is shown by the *Chimæra* and the statue of the Orator at Florence, by the Wolf in the Capitol at Rome, and by a magnificent lamp at Cortona. The earlier coins, which date from the 6th century B.C., show the influence of Asia Minor, while after the repulse of the Athenians in Sicily they are modelled on the coinage of Syracuse.

Many of the painted vases which have been found in such vast numbers in Etruscan tombs were either imported from Greece or made by Corinthian artists who had settled in Etruria, the subjects represented being drawn mainly from Greek mythology or the cycle of Homeric legend. Some of these vases may have been prizes won in the national games, and deposited in the tombs as cherished possessions of the deceased, together with his armour and his weapons. In like manner, the polished mirrors and jewelry of Etruscan ladies were commonly placed in their tombs. But the tombs are themselves the most characteristic works which the Etruscans have left behind them. They are of two kinds: the stone pyramid or cone with interior chambers, which is manifestly a survival of the tumulus, and the rock-cut chamber, which is a survival of the cave. But Etruscan tombs are not merely sepulchres; they are abodes for the spirits of the dead, constructed on the model of the abodes inhabited during life; they are provided with chairs and other furniture; useful and ornamental objects were deposited by the body of the deceased, while the walls were decorated with subjects from daily life, or scenes from the under-world. There is usually an ante-chamber in which the family could assemble at the annual funeral feast to do homage to the spirits of departed ancestors.

More than a hundred books have been written on the subject of the Etruscans and their monuments. The best general work is *Die Etrusker*, by K. O. Müller, edited by Dr Deecke (1877), supplemented by Deecke's *Etruskische Forschungen* and Paul's *Etruskische Studien*. The inscriptions have been edited by Fabretti in his *Corpus Inscriptionum Italicarum*; the tombs are described by Dennis, *Cities and Cemeteries of Etruria*; the mirrors

in Gerhard's *Etruskische Spiegel*. Corssen's great book, *Ueber die Sprache der Etrusker* (1874-75), is already obsolete. See also Cuno, *Vorgeschichte Roms* (vol. ii. 1888); Jules Martha, *L'Art Etrusque* (Paris, 1888).

**Etruria**, a village of Staffordshire, England, between Burslem and Hanley, with (1881) 4785 inhabitants. Here, on 13th June 1769, Josiah Wedgwood (q.v.) and Thomas Bentley (1731-80) opened their celebrated Etruria potteries, so named after the Etruscan ware.

**Ettmüller**, ERNST MORITZ LUDWIG, a learned German philologist, was born 5th October 1802, at Gersdorf, near Loban in Saxony, and studied first medicine, next German philology and history, at Leipzig and Jena, in 1833 was called to the Zurich Academy, and in 1863 to the university there, as professor of German Literature. Here he died, 15th April 1877. Ettmüller contributed enormously to the knowledge of Middle High German and Middle Low German by his scholarly editions of the literary monuments in these dialects. In 1840 he edited *Beowulf*, in 1850 an Anglo-Saxon chrestomathy; in the following year appeared his much-valued *Lexicon Anglo-Saxonicum*. Ettmüller also studied old Norse literature, edited the *Vœluspá*, translations, and a Norse reading-book. He also published original verse, and *Herbstabende und Winterächte*, *Gespräche über Deutsche Dichtungen und Dichter* (3 vols. 1865-67).

**Etrick Water**, a stream of Selkirkshire, rising on Capel Fell, and winding 32 miles north-eastward, past Thirlestane Castle, Tushielaw, and Philiphaugh, till, after a total descent of 1500 feet, it joins the Tweed, 3 miles below Selkirk, and 5 from the influx of its chief affluent, the Yarrow. In Etrick churchyard, towards the stream's source, lie Boston and Hogg the 'Etrick Shepherd,' Etrick Forest, erst so 'fair,' now treeless and pastoral, included all Selkirkshire, with parts of Peebles and Edinburgh shires. It was a favourite royal hunting-ground till James V.'s expedition against the Border thieves (1529), after which deer gave place to sheep. See Craig-Brown's *History of Selkirkshire* (1886).

**Etty**, WILLIAM, R.A., painter, was born at York, 10th March 1787, the son of a miller and spice-maker. For seven years he was apprenticed to a printer in Hull, working at art during every moment that could be spared from his incongruous employment. In the beginning of 1806 he removed to London, where in 1807 he became a student in the Royal Academy schools; and for a year he was a pupil of Sir Thomas Lawrence. His progress was at first slow; he competed unsuccessfully for prizes and medals; but in 1811 his 'Sappho' was hung in the Royal Institution, and his 'Telemachus rescuing Antiope' found a place on the walls of the Royal Academy. In 1820 he produced 'Pandora,' followed by 'The Coral-finders' (1820) and 'Cleopatra's Arrival in Cilicia' (1821). In 1822 he spent eighteen months in Italy—to which he had made a very brief visit in 1816—studying the works of the great masters, especially the Venetians, upon whom his own practice as a colourist is very distinctly founded. Two years later he was elected A.R.A., and soon after he began a series of large subjects—'Woman pleading for the Vanquished' (1825), three scenes from the history of Judith (1827-31), and 'Benahai' (1829), all of which were acquired by the Royal Scottish Academy, and now hang in the National Gallery of Scotland. In 1828 he attained full academic honours. Among his other chief works are 'Youth at the Prow and Pleasure at the Helm' (1832), in the National Gallery, London; 'The Sirens' (1837), in the Manchester Institution; and three subjects from the career of Joan of Arc,

executed shortly before his death, which occurred at York, 13th November 1849. As a colourist Etty ranks at the very head of the English school. His painting of flesh is distinguished by the utmost richness, delicacy, and refinement, and the glowing, blending lines of his draperies and of his landscape backgrounds are in admirable harmony with his figures. His drawing is too frequently mannered and inaccurate, though it occasionally possesses style and distinction. He was an indefatigable student of the living figure, and some of his most exquisite works are studies executed in the Life School of the Royal Academy, which he attended during most of his life. See *Autobiography in Art Journal* (1849); and *Life* by A. Gilchrist (1855).

**Étude**, a term used in music to designate compositions intended either to train or to test the player's technical skill. It is applied equally to pieces written for the beginner as to those written for the skilled expert, no matter what his instrument be.

**Etymology** (Gr.), the investigation of the origin or derivation and of the original signification of words. It forms a subsidiary part of the science of comparative philology, and, though it has occupied the attention of the learned and the curious in every age, it is only within the 19th century that its study has been pursued on really scientific principles. Ignorance, or what is still more dangerous, half-knowledge, has often suggested false etymologies, and many more have sprung from that excess of confident and self-sufficient ingenuity which will not take plain words like *beef-eater* and *welsh-rabbit* for what they are. Folk-etymology, properly so called, has played an important rôle in the development of languages. The words that the people have known from their infancy are for them things, but it is quite different with the new terms they meet. These arrest their curiosity, and, as they believe that every word has its signification, they seek for this, guided by resemblances of sound with words already known, and consequently reach conclusions often hopelessly distorted by false analogies. We see the same illogical process in the Old Testament interpretation of personal names, applied conveniently after the fact; in the Homeric explanations of the names of gods and men; in the quaint etymologies so common in medieval writers, and in such moderns as Thomas Fuller; in the vagaries of our Celtic topographers; and even in the pages of some modern dictionaries it is possible to find such a statement as that the English word *news* is derived from a certain conjunction of the points of the compass, N. E. W. and S. These whimsical etymologies were laughed at by Dean Swift, whose *ostler* = *out-stealer*, was a stroke of genius, but have not yet disappeared; and, indeed, the modern Englishman's ideas of method in etymology are hardly at all beyond the point attained by the grammarians of Alexandria and by Varro among the Romans. It was the birth of philology and the study of the languages of the East that made a scientific etymology possible. It no longer sought the relations of the words of a single language exclusively within itself, but extended its view to the whole group of cognate tongues, or, wider still, to a whole family, and became a new science under the name of Comparative Grammar. Grimm's Law was the first finger-post that pointed out the path; among his greatest successors are Curtius and Fick. The Teutonic revival within England in the 19th century commenced the history of English upon an historical method, from which has grown a really scientific English etymology, as seen in the dictionaries of Professor Skeat and Dr Murray. No more useful chart of warning could be given than the

former's canons for etymology: 'Before attempting an etymology, ascertain the earliest form and use of the word, and observe chronology. If the word be of native origin, we should next trace its history in cognate languages. If the word be borrowed, we must observe geography and the history of events, remembering that borrowings are due to actual contact.' See Curtius, *Grundzügen der Griechischen Etymologie* (5th ed. 1870); Fick, *Vergleichendes Wörterbuch der Indo-germanischen Sprachen* (3d ed. 4 vols. Gött. 1874-76); Kail Andresen, *Ueber Deutsche Volksetymologie* (1876); and A. S. Palmer's *Folk-Etymology* (1882).

*Etymologicum Magnum* is the name of a Greek lexicon, the oldest of the kind, professing to give the roots of the words. It appears to belong to the 10th century; the author's name is unknown. The etymologies are mere guesses, sometimes right, often wildly absurd; but the book is valuable, as containing many traditions and notices of the meanings of old and unusual words. There is an edition by Schafer (Leip. 1816); one by Sturz, called *Etymologicum Gudianum* (Leip. 1818); and another by Gaisford (Oxford, 1849).

**Etzel.** See **ATTILA**.

**Eu**, a town in the French department of Seine-Inférieure, on the Bresle, 2 miles from its mouth, and 21 N.E. of Dieppe by rail. It is remarkable for its fine 13th-century Gothic church, and for the Château d'Eu (1578), a low building of red brick, with high, tent-shaped roofs of slate. The seat from 996 of the Counts of Eu, a collateral branch of the Norman ducal line, after various vicissitudes Eu was purchased by Mademoiselle de Montpensier in 1675, whose fanciful taste has perpetuated itself in the decoration of the château; eventually, in 1821, it came to Louis-Philippe, who expended large sums on the embellishment of the château and its park, and who here received Queen Victoria in 1843. In 1874 Viollet-le-Duc restored it for the Comte de Paris. Pop. 4748.

**Eubœa** (ancient *Eubœia*, Turk. *Egripo*, Ital. *Negroponte*), an island of Greece in the Ægean Sea, runs parallel to the mainland for 98 miles, its breadth varying from 30 miles at its widest part to barely 4 at its narrowest. Area, 1420 sq. m., or a little smaller than Suffolk. About midway along its west shore, near Chalcis, the strait (Euripus) separating Eubœa from the mainland contracts to 120 feet, and is spanned by two bridges, resting on a rocky islet in the middle. The island, which has its long axis disposed north-west and south-east, is traversed longitudinally by a chain of mountains, rising in the centre, in Mount Delphi, to an elevation of 5725 feet. Iron and copper occur in the mountains; and at Carystos, in the south of the island, the marble called *cipolino*, so largely used in the buildings of Rome, is quarried. Hot springs (sulphur) exist in the north. Although the east coast is steep and rocky, the west side of the island slopes gradually, and its pastures support numerous herds of swine, sheep, and goats, whilst the arable land produces wheat, oil, figs, and wine. Honey also is an important article of trade. The declivities of the mountains are covered with forests. The climate is salubrious. The chief towns are Chalcis (q.v.) on the west coast and Carystos (pop. 4119) on the south coast. Pop. of the island (1879) 81,742, mostly Greeks and Albanians. Eubœa was peopled in the early historic times chiefly by Thessalian tribes and by Ionic Greeks, and afterwards by colonists from Athens, who formed a number of independent cities or states. Of these the most powerful were the rival commercial cities of Chalcis and Eretria; and it is around them and their exploits that the history of the island for some centuries mainly concentrates itself. After the Persian wars, however, Eubœa

was subjugated by the Athenians, under whose rule it continued till they, in their turn, were subdued by Philip of Macedon. By the Romans it was finally united with the province of Achaia under Vespasian. In 1351 it came into the possession of the Venetians, and received the name of Negroponte. In the year 1470 the island was taken by the Turks, in whose hands it remained till 1821, when the inhabitants rose to vindicate their independence at the call of the beautiful Modena Maurogenia. Subsequently (1830) it was incorporated in the kingdom of Greece.

**Eucalyptus**, a genus of Myrtaceæ, including about 150 species, which form the preponderant and most characteristic vegetation of the Australian forest. Their frequently enormous height (150–200 or even 400 feet, higher than the great Californian Wellingtonia or Sequoia; one fallen specimen recorded by Wallace must have been near 500 feet), their entire leathery glaucous leaves, which turn vertically with their edges to the sun, and so cast no shadow, and their frequently ragged bark and peculiar aromatic odour combine to give a uniquely peculiar and unmistakable character. Many species are known as gum-trees, from their resinous exudations. The Blue Gum Tree of Tasmania (*E. globulus*) is best known in Europe from its specially high reputation as a hygienic agent in damp, unhealthy, and malarious situations, and has hence been planted extensively in many parts of Italy, &c. Its value has been alternately ascribed to the antiseptic action of its camphor-like odours, and to its rapid growth (which sometimes even exceeds 10 feet per annum), and the consequent drainage of the soil through the enormous transpiration from the leaf-surfaces. The culture of Eucalyptus has also been introduced with good results into Algeria, Mexico, the Cape of Good Hope, &c. The Red Gum Tree, or Iron Bark Tree, yields a red astringent resin, known as Botany Bay Kino; and *E. robusta*, the Stringy Bark Tree, has also a beautiful red gum. *E. mannifera* yields a copious sweet exudation from its bark and leaves, which

*Eucalyptus Amygdalina.*

comes into commerce as Eucalyptus manna, and resembles genuine Manna (q.v.) in sweetness and aperient properties. That of *E. dumosa* is also gathered by the natives from the ground, on which it lies like hoar-frost, and is used as food. *E. Amygdalina* is remarkable both for its height and its girth. Eucalyptus timber is at first soft and easily worked, but soon hardens, and is often of

great value and durability. The bark of some species is useful as a source of tannin; whilst a liqueur made of Eucalyptus is drunk in Italy, and Eucalyptus honey is said to contain the valuable characteristics of the tree. The seeds were first sent from Melbourne to Paris by M. Ramel in 1854, and subsequently distributed to other parts of Europe. See Sir F. Müller, *Eucalyptographica* (Melbourne, 1881).

**Encharist.** See LORD'S SUPPER.

**Euchlorine** is a very explosive green-coloured gas, possessing bleaching properties, and is prepared by the action of strong hydrochloric acid on chlorate of potash. It is dangerously explosive by heat, and its composition is still a matter of discussion. It is variously supposed to contain chloric and chlorous acids, as well as free chlorine and oxygen.

**Euchre**, a game at cards, very popular in America, but not played until the first quarter of the 19th century. Euchre is played with a pack of thirty-two cards (all cards below a seven being rejected). The cards rank as at whist, with the exception of the *bowers*. Knave of the trump suit (*right bower*) is the best trump; knave of the same colour (*left bower*) is the next best, that card belonging to the trump suit. Each player receives five cards from the dealer, by two or three at a time, the top card being then turned up for trumps. When two play, the non-dealer either *orders up* the trump, and plays his hand, or *passes*. If he orders up, the dealer discards a card, and substitutes the trump card for it. If he passes, the dealer either *takes up* the trump (discarding as before), and the hand is played, or *passes*. This he signifies by turning down the trump. If both pass, the non-dealer may name any other suit for trumps (called *making it*), or may pass again. If he passes, the dealer may make it. If either makes it, the hand is then played; if both pass again, the hand is thrown up, and the opponent deals. If the hand is played, the non-dealer leads; the dealer plays, and must follow suit, if able. The highest card wins the trick; trumps win over suits, and the play continues as at whist. A player ordering up, or taking up, or making the trump, and winning five tricks (called a *march*), scores two; if he wins three tricks (called the *point*), he scores one. If he fails to make three tricks, he is *euchred*, and his adversary scores two. The game is five up. When four play, they cut for partners, as at whist. If the first hand passes, the second may assist, when his partner (the dealer) takes up the trump, and the hand is played. If a player has a very strong hand, he may *play alone*—i.e. single-handed against both adversaries. But he can only play alone when he or his partner orders up, or when his partner assists, or when he takes up the trump, or when he makes the trump. The hands are played as at whist, and the scores are as before; but if a lone player wins five tricks, he scores four. Euchre is sometimes played by three persons (*cut-throat euchre*); but it is not considered a good game, as not only do two players combine against the third, but at some points of the score a player may conspire against his partner. The game most in vogue among good players is the four-handed. The laws of four-handed euchre, revised by a committee of the Somerset Club, Boston, Mass., were adopted by that club on March 1, 1888.

**Euclid** is known to us almost exclusively from those of his works which have survived. Proclus in his commentaries on the first book of the *Elements* mentions that Euclid lived in the time of Ptolemy I. of Egypt, that he was younger than Plato, but older than Archimedes and Eratosthenes. Hence 300 B.C. may be taken as an approximate date for the middle of his career. He taught in

Alexandria, and probably was the founder of its illustrious mathematical school. His chief extant work is the *Elements* in thirteen books. Books i.-iv. and vi. treat of plane geometry; v. of proportion in general; vii.-ix. of the properties of numbers; x. of incommensurable magnitudes; xi.-xiii. of solid geometry. Besides the *Elements*, there are the *Data*, a collection of geometrical theorems, and the *Phænomena*, or appearances of the heavens. Regarding the genuineness of the *Section of the Scale, Introduction to Harmony, Optics, Catoptrics*, and *Divisions of Surfaces*, commentators are divided in opinion, though they lean rather to the view that most if not all of these writings are spurious. Some other works not now extant are attributed to Euclid. The only one of any importance was the treatise on *Porisms*. Euclid's *Elements* has been translated into many languages, and is probably better known than any other mathematical book. With many of its blemishes removed and its deficiencies supplied, it is still widely used in Britain as a text-book of geometry, though attempts have been made for the last 150 years to supersede it. On the Continent it has been almost universally given up, as in America; and after a few years, should secondary education come under state control, it will probably share the same fate in Britain also. Already one united attempt to supplant Euclid was made by the Association for the Improvement of Geometrical Teaching, but their syllabus of geometry and corresponding handbook have as yet failed to command any wide respect. See C. L. Dodgson's *Euclid and his Modern Rivals* (1879). The first printed edition of Euclid was a translation from Arabic into Latin, which appeared at Venice in 1482. The first printed Greek text was published at Basel in 1533. The most recent edition is that of Heiberg in five volumes (1883-88). The only edition which contains all the works attributed to Euclid is that by David Gregory, which appeared at Oxford in 1703. For an account of what the Greeks had done in geometry before Euclid's time, see Allman's *Greek Geometry from Thales to Euclid* (1889).

**Euclid** of Megara, a Greek philosopher, who has often been confounded with the mathematician of the same name. He was one of the chief disciples of Socrates, but had previously studied the dialectics of the Eleatics; on one occasion Socrates declared that his pupil's subtle logic might win sophists, but never men. After the death of his master (399 B.C.), Euclid established a school of his own, which received the name of the Megarian School. The basis of his system was the Eleatic dogma of a one, only, universal existence; and, blending with this the Socratic idea of the predominance of the moral element, Euclid held this one real existence to be the *Good*, though it receives various names under its special manifestations.

**Eudæmonism**, the doctrine that happiness (Gr. *eudaimonia*) is the chief good. See **ETHICS**.

**Eudiometer**. See **GASES**.

**Eudocia**, the name of several Byzantine princesses. Of these the most celebrated was the wife of Theodosius II. Pulcheria, the emperor's sister, who from her sixteenth year (414) had directed the government under the weak-minded emperor, chose Athenais (born 401), the beautiful and accomplished daughter of an Athenian sophist Leontius, to be her brother's wife. She renounced paganism, took the name of Eudocia, and was married to Theodosius in 421. Soon afterwards a violent rivalry arose between the two sisters-in-law. On the outbreak of the Nestorian controversy, Eudocia took the side of Nestorius, and Pulcheria, conspiring with Cyril of Alexandria, brought about his fall. During the last four years of Theodosius, Pulcheria was banished

from the court, and the doctrines of Eutyches (q.v.) and Dioscuros—the opposite of Nestorianism—were victorious at the 'Robber Synod' of Ephesus (449) through the influence of Eudocia. But shortly before the emperor's death (450) Pulcheria regained her former influence, while Eudocia fell into disgrace and retired to Jerusalem, where she spent the remainder of her life in works of piety and charity, and died in 460. Eudocia wrote a panegyric on the victories of Theodosius over the Persians, paraphrases of Scripture, and a poem on the legend of St Cyprian. The *Homero-cento* on the Life of Christ (consisting of 2343 hexameters made up of verses and half-verses culled from Homer), which are doubtfully attributed to her, was edited by Tencher (Leip. 1793). See F. Gregorovius, *Athenais* (1882).

**Eudoxus** of Cnidus, called by Cicero the prince of astronomers, flourished about 370 n.c. He studied under Plato for some time, and afterwards went to Egypt, where he derived much knowledge from the priests. He is said to have introduced an astronomical system of homocentric spheres into Greece, and the year of 365½ days, likewise to have distinguished true astronomy from astrology.

**Euganean Hills**, a range of well-wooded hills, with a north and south axis, lying S.W. of Padua in northern Italy. They owe their origin to eruptions of trachyte during the Jurassic period. The highest point, Monte Venda, reaches 1749 feet. On their slopes stand several villas, amongst them Petrarch's house at Arquè.

**Eugene**, PRINCE. François Eugène, commonly called Prince Eugene of Savoy, one of the greatest generals of his time, was born at Paris, 18th October 1663. He was the youngest of the five sons of Eugene Marice of Savoy-Caignan, Count of Soissons (grandson of the Duke of Savoy, Charles Emmanuel I.), and of Olympia Mancini, a niece of Cardinal Mazarin. He was intended for the church, but had a strong predilection for the camp, and, after his father's death (1673), his mother's banishment from court by command of the young king Louis XIV., and the latter's refusal to give him a commission, he indignantly renounced his country, and at twenty entered the service of the Emperor Leopold as a volunteer against the Turks. He early displayed extraordinary courage and tactical talent in the Turkish war, especially at the famous siege of Vienna in 1683, and rose rapidly in rank. In the Coalition War against Louis XIV. in Italy, he covered himself with the glory peculiar both to the soldier and the general; he became field-marshal in 1693, and overwhelmed the Turks, who left 30,000 dead on the field, in the famous battle of Zenta, September 11, 1697, which put an end to their power in Hungary. The outbreak in 1701 of the Spanish War of Succession recalled him to the command of the army of Italy, but though he displayed a strategy worthy of Hannibal, inflicted several severe defeats upon the French, and even captured the Duke of Villeroy in Cremona by a daring night-attack, he was prevented from effecting anything of importance by the smallness of his own forces and the skilful tactics of the Duke of Vendôme, who inflicted upon him a severe defeat at Luzzara (15th August 1702). Becoming in 1703 president of the council of war, he took the command of the imperial army in Germany, and helped Marlborough to gain the brilliant victory of Blenheim (13th August 1704). Eugene was checked at Cassano (August 16, 1705) by Vendôme, and twice wounded in the field, but after a daring march appeared before Turin and crushed the French in a complete defeat which closed their career in Italy. He shared with Marlborough the glory of the fields of Oudenarde (in 1708) and Malplaquet (in 1709); but, being

crippled in his resources by the retirement of Holland and England from the contest, he was unable to withstand the enemy on the Rhine, and his defeat by Villars at Denain (24th July 1712) was followed by other disasters, until the peace of Rastadt (6th March 1714) put an end to the war. On the recommencement of the war (in 1716) against the Turks, Eugene with but 64,000 men defeated an army of 150,000 men at Peterwardein, took Temesvar, and in the year 1717, after a desperate battle, carried Belgrade by assault. He had already lain for a month before the city contending against dysentery and a fever six times his own, when he determined to stake everything upon a general attack. In the bloody struggle Eugene received his thirteenth wound.

After the peace of Passarowitz (21st July 1718), he returned covered with glory to Vienna, where, during the succeeding years of peace, he laboured with unwearied energy in the cabinet. When the question of the succession to the throne of Poland brought on a new war with France, Eugene appeared again on the Rhine, but owing to insufficient resources and failing vigour he was unable to do more than keep the enemy out of Bavaria. After the peace, he returned to Vienna, where he died, 21st April 1736. Prince Eugene was of middling stature, his face thin and long; his eager dark eyes alone revealed the vigour of his nature. His dress was plain and simple like his manners; he had no passion but that of glory; no appetite save an inveterate relish for snuff. Although a strict disciplinarian and a general who risked his soldiers' lives as freely as his own, he was worshipped by his men, and he has gone down to posterity as a hero in popular song. As 'Prinz Eugen, der edle Ritter,' his memory is green with thousands who never heard of his campaigns. He introduced no new tactics in the art of war, and was deficient in the guidance and command of masses; but by his rapidity of perception and decision, and facility for turning to instant advantage existing circumstances, he raised the prestige of the Austrian arms to an eminence unequalled before or since his time. He successively served under three emperors, of whom he was wont to say that in Leopold I. he had a father, in Joseph I. a brother, and in Charles VI. a master. Compare Dumont, *Histoire Militaire du Prince Eugène* (with continuation, 1823-29), and the monographs of Kausler (1838-39), Arnetz (1858-59), Von Sybel (1861), and Col. Malletson (1888).

**Eugenia**, a genus of Myrtaceous trees and shrubs, allied to the myrtle, pimento, and clove. See MYRTACEÆ, PIMENTO, CLOVE.

**Eugenie**, Empress of the French. See NAPOLEON III.

**Eugenius**, the name of four popes, of whom the last is the most important. Gabriele Condolmiere was born in 1383 at Venice, and became pope as Eugenius IV. in 1431. The great event in his career was the schism created in the church by the proceedings of the Council of Basel, which had been convoked by his predecessor, Martin V., and showed a strong desire for ecclesiastical reform and a diminution of the papal power. Eugenius was compelled to flee from Rome in 1434 by an intrigue of the Colonna faction, whereupon he opened a new council, which met first at Ferrara, next at Florence, and issued a bull of excommunication against the bishops assembled at Basel, whom he pronounced to be 'a satanic conclave, which was spreading the abomination of desolation into the bosom of the church.' The Council of Basel formally deposed him from his pontifical office in 1439, and elected in his stead Amadeus, Duke of Savoy, under the title of Felix V. The conduct of France and Germany seemed to warrant this bold

step, for Charles VII. had introduced into the former country the decrees of the Council of Basel, with some modifications, through the Pragmatic Sanction (1438), and the same thing happened in Germany by means of the Decree of Acceptance (1439). At the Council of Ferrara, John Paleologus II., emperor of Constantinople, and upwards of twenty Greek bishops, presented themselves, and a union between the two great divisions of Christendom—the Greek and Latin Church—was thus for a moment effected in July 1439. In 1444 Eugenius was able again to enter Rome, and thence years later he died, just after signing a treaty of pacification by which Germany declared against the antipope. His pontificate was stormy and unhappy, and in his old age he regretted that he ever left his monastery. See BASEL (COUNCIL OF).

**Engubine Tables** (Lat. *Tabulae Iguvinæ*), the name given to seven bronze tablets, the inscriptions on which present a comprehensive and very remarkable memorial of the Umbrian language. They were discovered in 1444 at Gubbio (the ancient *Iguvium* or *Engubium*), where they are still preserved. The characters on four of the tablets are Etruscan, on two Roman, and on one partly Roman and partly Etruscan; the inscriptions run from right to left. The language employed, however, is in all cases the same, and differs both from Etruscan and Latin, but resembles somewhat the older forms of the latter and also the Oscan dialects, so far as we know them. The subjects of the inscriptions are directions concerning sacrificial usages and forms of prayer, and they seem to have been inscribed in the 1st and 2d centuries A.D. Philip Bonarota first published them in a complete form in Dempster's *Etruria Regalis* (2 vols. Florence, 1723-24). The first really judicious attempt at interpretation was that of Lanzi, in his *Saggio di Lingua Etrusca* (3 vols. Rome, 1789), who points out the important fact that they related to sacrificial usages, &c. Ottfried Müller, Lassen, Grotefend, and Lepsius continued their study; the last gave the most accurate copy of the inscriptions in his *Inscriptiones Umbricæ et Oscæ* (Leip. 1841). The best and most complete work on the language and contents of the tablets is that of Aufrecht and Kirchhoff, entitled *Die Umbrischen Sprachdenkmäler* (1849-51). See F. W. Newman, *The Text of the Iguvine Inscriptions, with Latin translation and notes* (1864); and Bréal, *Les Tables Eugubines* (Paris, 1875-78).

**Euhemerism**, the name usually applied to the historical theory of the origin of mythology from Euhemerus, a native of Messene and a contemporary of Cassander of Macedonia in the 4th century. In the course of a voyage to the Indian Sea he professed to have discovered an island called Panchaia, in which he found a number of inscriptions representing the principal gods of Greece as mere earth-born kings and heroes deified after death for their superior strength or capacity. His book, entitled *Hieru Anagraphê*, is lost, as well as its Latin translation by Ennius. It drew upon him the imputation of atheism, and its unblushing inventions made his name with honest inquirers, such as Strabo, a byword for mendacity. Its main theory, however, was adopted by many eminent men, including Polybius, as well as by several of the Christian assailants of paganism—by Minucius Felix, Lactantius, and St Augustine, who found the ground ready prepared for them in their efforts to strip Zeus and the other pagan gods of the attributes of deity. Later Greek writers carried the theory still further, eliminating everything supernatural or extravagant, and leaving only a string of tales perfectly credible and commonplace. Æolus became

an ancient mariner with a special knowledge of the winds, the Cyclopes a race of savages inhabiting Sicily, Atlas a great astronomer, and Scylla a fast-sailing pirate, as was also Pegasus, the winged horse of Bellerophon. Nor has this system yet disappeared from some of the current handbooks of mythology and history. Jupiter is still spoken of as a king of Crete, and Hercules as a Greek adventurer of uncommon strength, while the wars of Troy hold in the minds of many as respectable a place as the struggle between Athens and Sparta or Caesar's campaigns in Gaul. Euhemerism was the favourite theory with the *soi-disant* philosophical historians of the 18th century in France, and the translation of Abbé Banier's great work, *The Mythology and Fables of Antiquity, explained from History* (Lond. 6 vols. 1739), extended it to England. To this school belong also writers such as Vossius, Bochart, and Huet, who find traces not merely of profane but of sacred history in Greek mythology. Saturn is identified with Noah; his sons, Zeus, Poseidon, and Hades, with Shem, Ham, and Japhet; while Vulcan corresponds with Tubal Cain, and Phaethon with Elijah. The latest and ablest exponent of sacred euhemerism is Mr Gladstone, who sees in Zeus, Hades, and Poseidon the dimmed figures of the Christian Trinity; in Apollo, the Jewish Messiah; and in his mother Latona, the woman whose seed should bruise the serpent's head. Herbert Spencer is also an euhemerist in his explanation of the origin of religion. He bases all the religious emotions on primitive ancestor-worship, and explains totemism, a condition everywhere present in the savage world, as due originally to mere human nicknames, which were gradually forgotten, and afterwards came to have a sense of mystery connected with them.

**Eulenspiegel**, TILL, the prototype of all the knavish fools of later time, is said to have been born in the village of Kneitlingen, near Schöppenstadt, in Brunswick, about the end of the 13th century. His father was called Klaus Eulenspiegel, and his mother Anna Wortbeck. He was thrice baptised, in the font, in mud, having been dropped from his mother's arms, and finally in hot water, to cleanse him from the mud; he afterwards wandered over Europe, and had many comical adventures, and played many rough practical jokes and tricks on the people whom he met with. His tomb is shown at Mölln, about four leagues from Lübeck, where tradition makes him die about 1350; but the inhabitants of Damme, in Belgium, also boast of having his bones in their churchyard, and place his death in 1301. Many regard Eulenspiegel as an altogether imaginary person, whose name was used merely to father a cycle of medieval tricks and adventures; others argue that there were two historical individuals of that name, father and son, of whom the former died at Damme, and the latter at Mölln. The stories that circulate in Germany under Eulenspiegel's name were not collected, as the book containing them itself informs us, till after Eulenspiegel's death, and without doubt were originally written in the Low German tongue; from Low German they were translated into High German by the Franciscan Thomas Murner, and this translation was followed in all the old High German editions of the work. At a later period it underwent considerable alterations at the hands of both Protestants and Catholics, who made it a vehicle for the expression of their own likes and dislikes. The oldest known edition is that printed at Strasburg in 1516, of which but one copy is known to exist—that in the British Museum (new ed. Halle, 1885). Another was issued in 1519, a new edition of which was edited by Lappenberg (Leip. 1854). The next impression, that of 1520-30, originated at Cologne (not in Lower Saxony),

and was reproduced by photo-lithography at Berlin in 1865. A metrical version, *Der Eulenspiegel reimweis*, was made by Fischart, and published at Frankfurt in 1571. For centuries it has been a favourite *Volksbuch*, not only in Germany, but in many other countries. Translations of it exist in Bohemian, Polish, Italian, English (as a miracle play: *A merye Jest of a man that was called Howleglas*), Dutch, Danish, French, and Latin. Simcock gave a good restoration in *Ein kurzweilig Lesen von Till Eulenspiegel, nach den ältesten Quellen* (Frankfurt, 1878); such works as *Till Eulenspiegel, modernes Heldengedicht*, by Böttger (Leip. 1850), and *Till Eulenspiegel Redivivus, ein Schelmenlied*, by J. Wolff (Berlin, 1875), owe to it little beyond the name. A version of the story is given in Roscoe's *German Novelists*.—Eulenspiegel is the origin of the French word *espégle* ('waggish'). Eulenspiegel became in French '*Ulespiègle*', which, contracted into *Espégle*, became a generic name for a wag.

**Euler**, LEONHARD, a distinguished mathematician, born 15th April 1707, at Basel, where he afterwards studied under John Bernoulli, and was the friend of Daniel and Nicholas Bernoulli. At the age of nineteen he was second in the contest for a prize offered by the Academy of Paris for the best treatise on the masting of ships. His friends the Bernoullis had been called to St Petersburg by Catharine I, when she founded the Academy, and in 1727 they induced Euler to settle in that capital, where in 1730 he was appointed to the chair of Physics, in 1733 of Mathematics. From that time he continued to labour in the field of mathematics with an ardour that excited the generous rivalry of the Bernoullis. More than half the mathematical treatises in the 26 quarto volumes published by the St Petersburg Academy from 1727 to 1783 are by Euler, and at his death he left more than 200 treatises in MS., which were afterwards published by the Academy. The French Academy of Sciences awarded him its prize on several occasions, and in 1740 his treatise on Tides shared the prize with those of Maclaurin and Daniel Bernoulli. In 1741 he accepted the invitation of Frederick the Great to Berlin, and there published a great number of valuable papers. In 1766 he returned to St Petersburg, where he died, September 18, 1783. The last years of his life were spent in total blindness, amid which he still pursued his researches, dictated his well-known *Introduction to Algebra* to his servant, and perfected, with some assistance, his theory of the moon's motion, constructing new tables, and carrying in his wonderful memory all the elaborate computations involved in his difficult task. After his return to St Petersburg, he also prepared his *Lettres à une Princesse d'Allemagne* (3 vols. 1768-72), in which, along with much theory unsoundly applied, there is a clear exposition of the most important facts in physics. Euler was of an upright, amiable, and religious character, and a man of wider general culture than might have been looked for in one who pursued his special studies so keenly. His proper domain was the abstruser parts of pure mathematics, and here his principal works include his Theory of Planetary Motion, Introduction to the Analysis of Infinities, Institutions of the Differential and of the Integral Calculus, and Dioptries, which are all, as well as his *Opuscula Analytica*, in Latin. See Rudio's *Leonhard Euler* (Basel, 1884) and *Die Basler Mathematiker* (ib. 1884).

**Eumenides** (Gr., 'the benign'), the euphemistic name for the Erinyes, the Roman *Furiae* or *Direæ*, three fearful winged maidens who dwell in the depths of Tartarus, daughters of Earth or of Night, represented with serpents twined in their

hair, and with blood dripping from their eyes, whose function as early as Homer and Hesiod is to punish men both in this world and after death for such crimes as perjury, murder, and the violation of filial duty and of the rite of hospitality. They were regarded also as goddesses of Fate, somewhat like the Moiræ or Fates, and they had a share in the grim providence which led the doomed ones into the way of calamity. A part of their function was also to hinder man from acquiring too much knowledge of the future. Their number is usually three, and their names Alecto, Megæra, and Tisiphone; but sometimes in the poets they appear as one, and we find a whole chorus of Erinyes in the tragedies of Æschylus. The later poets and sculptors represented them in the more pleasing form of winged virgins, attired in the garb of huntresses, bearing torches in their hands, and with a wreath of serpents round their heads. Gradually, they came to be considered goddesses of the infernal regions, who punished crimes after death, but seldom appeared on earth. In Athens their worship, which, like that of the other infernal deities, was conducted in silence, was held in great honour. The sacrifices offered to them were black sheep and libations of *nephelia*, honey mixed with water. The turtle-dove and the narcissus were sacred to them. They had a sanctuary in the vicinity of the Areopagus, and one at Colonus.

**Eumolpus** (the 'sweet singer'), in Greek Mythology, the son of Poseidon and Clione, was brought up in Ethiopia, whence he went to Thrace. Afterwards passing into Attica, at the head of a body of Thracians, to assist the Eleusinians in their war against Erechtheus, he and his sons were slain in battle. He was regarded as the founder of the Eleusinian mysteries. An illustrious Athenian family, the *Eumolpidae*, claimed descent from Eumolpus, and held the office of priests of Demeter in Eleusis.

**Eunomius**, the leader of an extreme sect of Arians, called after him Eunomians, was born at the village of Dacora, in Cappadocia. He attached himself to Aëtius, then at Alexandria, and became his disciple and associate. Through the influence of Eudoxius he became Bishop of Cyzicum about 360, but was compelled in a short time to resign his see, and after this he came forward as the leader of a party. His confession of faith, sent to Theodosius in 383, was rejected, and Eunomius was seized at Chalcedon, and sent first to Mœsia, then to Cappadocia, where he was still living in his native village in 392. According to Philostorgius, he was unhandsome, with white spots (Gr. *alphoi*) on his face, and had a stammering tongue in spite of his eloquence. The doctrines of Eunomius and Aëtius, which were simply those of Arius carried to an extreme, were condemned at the second Œcumenical Council. After his death the Eunomians (who were also called Exucotians, Heterousiasts, and Anomœans) broke completely with the orthodox church. Their internal disunion quickly put an end to the party. His only extant writings are his two apologies and his confession. See **ARIUS**; and Klose, *Geschichte und Lehre des Eunomius* (Kiel, 1833).

**Eunuch** (Gr. *eunouchos*, 'one who has charge of a bed'; *eunû*, 'a bed') is, etymologically, a man intrusted with the charge of women's apartments in the East; but the word means always a person who has been castrated, in order to serve in the harem. The barbarous custom of castrating men is usually an accompaniment of polygamy, and seems to have been earliest practised in Africa; but it established itself, along with Asiatic vices, in the Roman empire. At the Byzantine court the eunuchs often played an

important rôle, and became so prominent in affairs of state that the word eunuch came practically to be the name of a great state-officer, the chamberlain. The Italian word *castrato* is that usually employed for a man who has as a youth suffered castration to prevent his voice from breaking. Such persons preserve the pure, clear, high timbre of the boy's voice, and add the grown man's lung power; and in spite of the canonical law and more than one papal bull, came to be highly prized in Italy for singing in churches, in the opera, and at concerts, and till of late were common. In the 18th century it was estimated that 4000 boys were yearly castrated for musical purposes. The castrati were at one time not unknown in France, Germany, and England, as connected with the Italian opera. Many individuals attained high eminence as really great singers. See **CASTRATION**.

**Euomphalus**, a large genus of fossil gastropodous shells, characterised by its depressed and discoidal shell, with angled or coronated whorls, five-sided mouth, and very large umbilicus.

**Euonymin** is an extract from the bark and root-bark of the *Euonymus atropurpureus*, the Spindle Tree (q.v.), or Wahoo, a shrub indigenous to the United States. It is a mixture of a number of substances which have not yet been thoroughly investigated. It has long been used in America as a cholagogue, tonic and diuretic, but in Britain is employed solely for its stimulant action on the liver.

**Eupatoria** (formerly *Koslov*), a thriving maritime town of Russia, in the government of Taurida, on a bay in the west of the Crimea, 40 miles NW. of Simferopol. The principal building is the Tartar mosque, built in 1552. Eupatoria exports corn, hides, wool, and salt, and manufactures candles, soap, leather, and marine engines. Its harbour is shallow, and is sheltered only from the north and north-east winds. Pop. 13,416, consisting of Tartars, Karaite Jews, Armenians, and Greeks. The town was taken from the Tartars by the Russians in 1783, in September 1854 was occupied and fortified by a portion of the Anglo-French invading army, and in February 1855 was the scene of a Turkish defeat of the Russians.

**Eupatorium**, a large genus of Compositæ, allied to Coltsfoot (*Tussilago*) and Butterbur (*Petasites*). The species are mostly tropical and temperate American, but *E. cannabinum* is the common Hemp Agrimony of riverbanks and marshy places, formerly reputed in domestic medicine. The roots of several American species are still so employed, notably Thorough-wort (*E. perfoliatum*) and *E. purpureum*. Their astringency gives several South American species a reputation in the treatment of wounds and snake-bites; and the Guaco, reckoned of almost universal efficacy in tropical America, is derived from the allied *Mikania guaco*. The roots of some are used in tanning, and others yield a variety of indigo.

Hemp Agrimony  
(*Eupatorium cannabinum*).

**Eupatrides**, the first class of citizens in ancient Athens, corresponding to the Roman *optimates*, 'the aristocrats or nobles.' The second class was the *geomoroi*; the third, the *demiourgoi*. Just as did the Roman patricians, the eupatrides retained the priestly offices after the establishment of the democracy.

**Eupen**, a manufacturing town of Rhenish Prussia, in a beautiful valley on the Vedre, close to the Belgian frontier, and 12 miles by rail S. of Aix-la-Chapelle. It has flourishing woollen manufactures, besides dye-works, machine-shops, breweries, &c. It owes its prosperity chiefly to French refugees, who settled here after the peace of Lunéville (1801); in 1814 it came from Limburg to Prussia. Pop. (1875) 14,895; (1885) 15,441, almost all Catholics.

**Euphemism** (Gr. *eu*, 'well,' and *phēmi*, 'I speak'), a figure of rhetoric by which an unpleasant or offensive matter is designated in indirect and milder terms. Thus, instead of directly calling up an unpleasant image by the word *died*, we may say 'he was gathered to his fathers.' The ancient Greeks used a multitude of euphemisms, to avoid words that were thought to be ominous of evil, or offensive to the unscen powers. They spoke, for example, of the Eumenides, or 'benign goddesses,' instead of the Furies; just as the elves and fairies of more modern folklore used to be spoken of as 'good neighbours.' This instinct of politeness in speech, which seeks to hint at an unpleasant or an indelicate thing rather than name it directly, has had much to do with changing the significations of words: thus, 'plain' has usurped the sense of *ugly*; 'fast,' of *dissipated*; 'gallantry,' of *licentiousness*. It is doubtful whether this modern process is completely to the advantage of our language, which has already lost much of its ancient noble simplicity, and may lose more from a mawkish and prurient nastiness which fondly imagines itself the mother of nice ideas.

**Euphonium**, a bass Saxhorn (q.v.).—The *Euphonon* was a variation of the Harmonica (q.v.), invented by Chladni in 1790.

**Euphorbia**, OIL OF, or OIL OF CAPER SPURGE, an extremely acrid fixed oil, obtained by expression, or by the aid of alcohol or ether, from the seeds of the Caper Spurge (*Euphorbia lathyris*),

Caper Spurge (*Euphorbia lathyris*).

a plant common in many parts of Europe, and naturalised in some places in Britain (see SPURGE). Oil of euphorbia has much resemblance to croton-oil in its properties, although less powerful, and is

sometimes used as a substitute for it, in doses of from three to ten drops. It is good for use only when recently extracted.

**Euphorbiaceæ**, a very extensive order of dicotyledons, probably allied to Tiliaceæ and Malvaceæ, containing upwards of 3500 known species—trees, shrubs, and herbaceous plants, of the most extraordinarily varied, often even cactus-like habit. They abound chiefly in warm countries, and most of all in tropical America. The few species found in the colder parts of the world are all herbaceous. The common Box (if this be indeed truly euphorbiaceous) reaches a more northern limit than any other shrubby species. The other British species are different kinds of Spurge (Euphorbia) and Dog's Mercury (Mercurialis). The Euphorbiaceæ usually abound in an acrid and poisonous milky juice; although there are species of which the juice is bland or becomes so through the application of heat. The conception of Robert Brown, that the peculiar 'flower' in Euphorbia, &c. is really a reduced inflorescence, has given rise to much controversy (see FLOWER). Amongst those most remarkable for the acidity of their juice are the Manchineel (q.v.) and *Ezecaaria agallocha*, an East Indian tree—formerly supposed to yield one of the kinds of aloes wood—the smoke from the burning of which is extremely dangerous to the eyes, and of which the juice sometimes blinds the woodcutter. Many of the Euphorbiaceæ are valued for their medicinal properties. Thus, the juice of some of the spurges, the roots of others, the bark of different species of Croton (Cascarilla Bark, Copalche Bark), &c. are used in medicine; and to plants of this order we are indebted for castor-oil, croton-oil, &c. A few of the Euphorbiaceæ yield fragrant balsamic products (see CROTON); a few, although their juice is poisonous, yield a wholesome starch in considerable abundance (see MANIOC); a few are cultivated and used as pot-herbs, particularly species of Plukenetia in the East Indies; a few yield wholesome and agreeable sub-acid fruits, as *Cicca disticha* and *C. racemosa* in the East Indies; the seeds of some are edible, as those of the Candle-nut (q.v.), &c.; the oil of the seeds is also in some cases used for food, like other bland oils, but more frequently for burning, as castor-oil, candle-nut oil, the oil of *Eleococca verrucosa* in Japan and Mauritius, and the solid oil of *Stillingia sebifera*, which is used in China for making candles, and in medical preparations as a substitute for lard. Others yield dyestuffs. The timber of some of the Euphorbiaceæ is valuable—e.g. African Teak (q.v.). Many species are cultivated in gardens and hot-houses, more frequently for their curious appearance than for their beauty; but the large, deep crimson bracts of *Poinsettia pulcherrima*, a native of Mexico, make it a very attractive plant.

**Euphorbium**, an extremely acrid gum-resin, obtained from several species of Euphorbia or Spurge (q.v.), as *E. officinarum* and *E. antiquorum* in the north of Africa, Arabia, and the East Indies, and *E. Canariensis* in the Canary Islands. It is obtained by incisions in the branches, whence issues a corrosive milky juice, which dries in the sun, and becomes a yellowish-gray, waxy gum-resin. The persons who collect it are obliged to defend their mouths and nostrils by a cloth, as its particles produce incessant sneezing, violent inflammation of the nostrils, and a very painful burning sensation in the mouth. On account of its excessive acidity its use is now almost entirely confined to veterinary medicine, although it is still occasionally mixed with Burgundy pitch or other substances to make rubefacient plasters for chronic affections of the joints; and its powder, mixed with much starch or flour, has been employed as an *errhine* in chronic

affections of the eyes, ears, or brain. It was formerly administered as an emetic and drastic purgative, but is dangerously violent in its action.

**Euphrasy.** See EYEBRIGHT.

**Euphrates** (Pers. *Ufratu*, Heb. *Phrat*, Syr. *Ephrat*, Arab. *Furat*) is the largest river in Western Asia, and, with the Tigris, forms the most important river-system of that part of the Continent. It has its source in the heart of Armenia in two branches—the Kara-Su (270 miles) and the Marad (300 miles), of which the former rises a few miles NE. of Erzerum, and the latter over 130 miles to the east, near Lake Van—uniting in about 39° N. lat. and 39° E. long., close to Keban Maadin (2664 feet above the sea). From here the united stream flows in a general southerly direction, and breaks through the Taurus in a succession of rapids and cataracts for about 40 miles, emerging at Sumeysât (the ancient *Samosata*), and passing Bir, at which point it is 100 miles distant from the nearest shore of the Mediterranean. Flowing south, it separates for a considerable distance Mesopotamia from Syria and the deserts of Syrian Arabia; then curving to the south-east, it flows on to Kurna, where it is joined by the waters of the Tigris; and the joint river, taking the name of the Slat-el-Arab, empties itself by several arms (only one of which is navigable by large vessels) into the Persian Gulf, 60 miles below Basra, after a course of fully 1700 miles. The principal of its few tributaries after leaving the mountains are the Sajur on the right, and the Balik-su and Khabûr on the left bank, besides the Persian river Karûn, which enters the estuary at Mohammera. The chief towns now on its banks are Sumeysât, Bir, Ana, Hit, and Hilla, Basra lying really on a creek a short distance from the main stream; the river between Ana and Hit is studded with islands, many of them inhabited. The Euphrates is more or less navigable for light craft as far as Bir (nearly 1200 miles); war-vessels can ascend to the junction at Kurna (120 miles), and Turkish government steamers make trips annually between Hilla and Balis while the river is in flood (April to August). In ancient times, when canals and embankments regulated the river's inundations, these exercised the same beneficial effect on the country as those of the Nile on Egypt; but barely a hundredth of the old system is maintained to-day. Numerous remains of ancient cities are still to be traced near the banks, such as the famous site of Babylon, and the Birs Nimrûd (see BABYLONIA).

**EUPHRATES ROUTE TO INDIA.**—Before the Suez Canal was constructed there was a difference of opinion which of the two ancient trade routes to India—that by Suez, or the other by way of Scanderoon and down the Euphrates Valley—was to be preferred. In 1830 Captain F. R. Chesney, R.A., reported to government that the connection of the Mediterranean and Red seas by the Suez Canal was practicable, in spite of the adverse verdict of Bonaparte's engineers. In 1831 he enlarged his survey by descending the Euphrates, and established the fact that the river was navigable for vessels of moderate draught, at least as high up as Ana. In a report (*On the Navigation of the Euphrates*, 1833) he maintained that this was the shortest possible route to Bombay, with less open sea than any other; that the country it would open out was rich in natural products, metals, wheat, cotton, silk, madder, &c.; and that there was little opposition to be apprehended from the Arab tribes. His conclusions were supported by men of influence, such as Sir Stratford Canning, Sir R. Gordon, Lords Lansdowne and Ripon; and in 1834 in the House of Commons Lord Althorp brought in a grant of £20,000, for the purposes of

an expedition to survey the Euphrates route, to which the India Board added £5000. The expedition, comprising engineers, sappers and miners, and artillerymen, started under Chesney's command in 1835, and after encountering much opposition from Ibrahim Pasha, and overcoming the only serious natural obstruction on the route, the 140 miles of rocky, mountainous country between Scanderoon and the Upper Euphrates, they launched two iron steamers on the Great River at Birejik, and began the descent, in March 1836. The channel was found to be difficult, but not impracticable; and, though one steamer sank, its loss was due to a simoom of unusual violence, and not to the obstacles presented by the river-bed or currents. The other steamer safely reached the mouth, and the survey justified Chesney's predictions. No further step, however, was taken, either by government or by private enterprise, until in 1856 a company was formed, chiefly by the energy of Sir W. Andrew, for the construction of a railway along the route already surveyed. Adapting himself to the new phase of his scheme, Chesney again went to the Levant, obtained a firman from the sultan, and with the help of Sir John Maeneill laid down a practicable route for the railway, by which the passage from England to Karchi (Kurrachee), the nearest port of India, would be 1000 miles shorter than by way of Suez. The immense political importance of the scheme, by which Hither Asia would necessarily be subject to overwhelming British influence, was its destruction. Everything seemed settled, the concession was granted by the Porte, when, in deference, it is said, to the jealousies of foreign powers, Palmerston threw over the scheme. Another attempt in 1862, with a new company under the chairmanship of Lord Stratford de Redcliffe, ended in a similar collapse, since government refused its countenance. As an alternative to the Suez Canal, and as an instrument for opening up a rich but neglected country, the Euphrates Valley route would still be a valuable channel of commercial and military communication for the British empire.

See Chesney, *Expedition for the Survey of the Rivers Euphrates and Tigris* (1850); *Narratives of the Euphrates Expedition* (1868); *Evidence before Select Commission* (1872); also *Life of General F. R. Chesney* (1885); V. L. Cameron, *Our Future Highway* (2 vols. 1888); and W. F. Ainsworth, *The Euphrates Expedition* (1888).

**Euphrosynê** (i.e. 'the joyous one'), one of the Graces (q.v.).

**Euphuism**, a term used in English literature to denote an affected and bombastic style of language, fashionable for a short period at the court of Queen Elizabeth and in the literature of the time. The word was formed from the title of the book which brought the style into vogue, the *Euphuus* of John Lyly (q.v.). Euphuism is usually taken to have been an exaggeration of the prevailing Italian taste; but Dr Landmann (*Der Euphuismus*, Giessen, 1881) has sought to prove that the peculiarities of Lyly's style are directly to be traced to Antonio de Guevara (1490-1545), Spanish court preacher, historiographer, bishop, and moralist. His chief work was an historical romance, based on the life and the meditations of Marcus Aurelius, one English translation of which by Lord Berners appeared in 1531, another by North (as *The Dial of Princes*) in 1558-67. This work, exceedingly popular in the last-named translation, has the same characteristics of style as Euphuism, which has even been called *Guevarism*. In *Holofernes* in *Love's Labour's Lost*, and in Sir Piercy Shafton in the *Monastery*, Euphuism is caricatured.

**Eupoda**, a section of vegetarian beetles in the Tetramerous division. The gorgeous Kangaroo-

beetles of tropical Asia and Africa, the Donaceæ on water-plants, the species of *Crioceris* on lilies, asparagus, &c. are examples. Comparatively few are British.

**Eurasians** is a convenient term for the offspring of Europeans and Asiatics, and is chiefly used in India of the children by European fathers of Hindu mothers, and their descendants. It occurs in *A Few Local Sketches*, by J. M. (Calcutta, 1844).—The term Eurasian is also used in geography for facts true of Europe and Asia (Eurasia) taken as one continent.

**Eure**, a department of Normandy, immediately south of the department of Seine-Inférieure, contains an area of 2290 sq. m. Pop. (1881) 364,291; (1886) 358,829; the decrease has gone on steadily since 1846 (423,247), small families, often limited to one child, prevailing among all classes. The surface is generally level; the highest point reaches only 790 feet. The principal river is the Seine. The Eure, from which this department derives its name, and the Rille, both affluents of the Seine, are the only other important rivers; the Eure, which rises in the department of Orne, has a course of 141 miles, and is navigable for 54 miles. The climate is mild, moist, and foggy. Along the Seine the soil is in some parts sandy, stony, and barren, but the greater part is very fertile. The chief natural products are corn, hemp, flax, vegetables, and fruit, particularly apples and pears, from which large quantities of cider and perry are made. The breeding of cattle, horses, and sheep is favoured by extensive meadows and pasture-lands. Iron is found in considerable quantities. There are extensive iron and copper works and pin-manufactories. Cotton goods, cloth, linen, paper, and beet-sugar also are manufactured. The department is divided into five arrondissements—Evreux, Louviers, Les Andelys, Bernay, and Pont-Audemer. The capital is Evreux.

**Eure-et-Loir**, a department of France, to the south of the preceding, with an area of 2260 sq. m. Pop. (1872) 282,622; (1886) 283,719. It is watered mainly by the Eure in the north, and the Loir in the south. It is in general level, the east and south being occupied by high and extensive flats; while in the west the scenery is finely varied by wooded hills and valleys. The soil is fertile, and good crops of wheat and oats are raised, besides considerable quantities of vegetables and fruit; cider is prepared, and some wine. Stock-raising also is of importance, and iron and a few other minerals are worked. The rivers, though not navigable, furnish valuable water-power for the numerous mills on their banks; besides foundries, there are manufactories of beet-root sugar, cotton, wool, silk, paper, boots, and hats. The department is divided into the four arrondissements of Chartres, Châteaudun, Dreux, and Nogent-le-Rotrou, with the town of Chartres for capital.

**Eureka**, (1) a port and capital of Humboldt county, California, on Humboldt Bay, chiefly noteworthy for its mild, equable climate. It has several lumber-mills, and exports great quantities of redwood lumber from the giant forests around. Pop. 2639.—(2) A mining town, capital of Eureka county, Nevada, 90 miles by rail S. of the Palisades station on the Central Pacific Railroad. Here are silver and lead mines. Pop. 4207.

**Euripides**, the latest of the three great Greek tragedians, was born at the time when the Persian attack upon the freedom of Greece was being repelled in a series of glorious victories; and this fact is expressed in the story that he was born 480 B.C. at Salamis, whether the Athenians had fled, and where the Persian fleet was defeated in that year. The first half of his life coincided

with the growth of the Athenian empire, the second with its decline. Æschylus, the first of the three tragedians, a man of forty when Euripides was born, probably had died before Euripides produced his first play—at which time Sophocles had already been thirteen years before the public, and Aristophanes, the comedian, who was to be the constant opponent of Euripides, was not yet born. Euripides was the son of wealthy parents, who probably had made their fortune by trade, for Aristophanes (*Ach.* 478, *Ran.* 840) banters him on the subject with jests which would have been pointless had they not contained some truth. Tradition says that his father intended him to compete in the national athletic festivals of Greece; and this may account for Euripides' pronounced dislike of athletes (*Frag.* 284). He then took to painting, but, like Théophile Gautier, abandoned it for literature; and he has indeed the painter's eye for an effective situation. Tradition represents him as the friend of Socrates, and the pupil of Prodicus, Protagoras, and Anaxagoras; and he does more than once reproduce in his plays Anaxagoras' doctrine of the origin of all things from the vedlock of Earth and Air (cf. *Frag.* 836, 890, 935; *Ar. Ran.* 892). He is said to have been married twice, and to have had three sons. Scandal has been busy with his wives, but there can be no truth in it, otherwise we should have heard of it from Aristophanes; and his reputation as a woman-hater is not confirmed by an impartial study of his plays. How many dramas he wrote we do not know, but the names and some fragments of about eighty are known to us, and of these eighty we possess eighteen complete. He won the tragic prize only five times, and he died 406 B.C. at the court of Archelaus, king of Macedonia. His habits were those of the scholar and the recluse. He was one of the first and the few private persons in Greece to possess a library (cf. *Hipp.* 452, 954; *Iph.* A. 798; *Alc.* 962; *Frag.* 629; *Ar. Ran.* 943, 1403). He took no such part in public life as did Æschylus and even Sophocles. In politics he was a moderate, approving of democracy (*Frag.* 628), but not of demagogues (*Hec.* 132, 254). His views of life on the whole were pessimistic: he did not share Aristophanes' romantic illusions as to the past, and the contemplation of the future could bring no comfort in an age when the doctrine of progress had not as yet been formulated. The immoralities of the accepted mythology shocked him as well as other thinkers; but his philosophy sufficed neither to shake off the old religion nor to reconcile him to it. The names and probable order of the surviving plays are: *Alcestis*, *Medea*, *Hippolytus*, *Hecuba*, *Andromache*, *Supplices*, *Heracleida*, *Troades*, *Helena*, *Phænissæ*, *Orestes*; the *Bacchæ* and *Iphigenia in Aulis* were put on the Athenian stage only after the author's death; and it is uncertain to what period belonged the *Ion*, *Hercules Furens*, *Iphigenia in Tauris*, *Electra*, and *Cyclops*, whilst it is doubtful whether the *Rhesus* is genuine. Whereas the characters in the plays of Æschylus and Sophocles had been heroic in their proportions and greater than life, Euripides set to work to be human. And in this we have the secret both of his success and of his failure: of his failure, because he made the mistake of imagining human life to be the same thing as everyday life; of his success, because in his treatment of everyday motives and emotions he was, 'with his droppings of warm tears,' the 'most tragic of the poets.' His skill as a playwright is of the highest order; he can construct plots which are exciting beyond anything attempted by his predecessors, and he has an unerring instinct for a 'situation.' But he has all the unscrupulousness of the practical playwright: in his consuming desire to get on to the situation as rapidly as possible, and to bring the curtain down sharp on it, he

substitutes a bald prologue for a proper exposition and, instead of working out the dénouement, makes a *Deus ex machina* cut the knot of the situation. For the sake of the same all-important consideration he will sacrifice consistency in character-drawing, and transgress all the bounds of artistic self-restraint. His popularity increased, indeed we might almost say began, after his death; his plays were 'revived' on the stage more frequently than those of Æschylus or Sophocles; they fill a much larger place in the mind of Aristotle, as appears from his *Poetics*, than those of the other two tragedians; and the number of his plays that have survived is greater than both theirs put together. Nor can we ascribe this wholly to a decline in taste, when we remember that Euripides was a favourite with Theocritus, Virgil, Ovid, Horace, Milton, and Browning. The oldest MSS. known to us go back only to the 12th century, and are very corrupt. The *editio princeps* (Florence, 1496) contains only four plays; the Aldine (1503), eighteen. The critics who have done most for the text are Porson (1797), Elmsley (1813), G. Hermann (1838), C. Badham (1851). The most convenient text is that of A. Nauek (Leip. 1885).

**Eurípūs.** See CHALCIS, EUBŒA.

**Euroclydon,** in the A.V., following the ordinary Greek text, was the tempestuous wind by which St Paul's ship was wrecked (Acts, xxvii. 14). The revised translation, taking the Greek reading *euraklyon*, has *Euraquilo*, 'a north-easter.' This is sometimes identified with the Bora (q.v.).

**Euro'pa,** the daughter of the Phœnician king Agenor, whom Zeus, in the form of a bull, bore off to Crete, where she became the mother of Minos, Rhadamanthus, and Sarpædon.

**Europe.** Europe is historically and politically by far the most important of the five great divisions of the world. It is, however, next to Australasia, the smallest in area, though, in proportion to its size, the most densely peopled. Geographers are agreed that, apart from its history and significance for the history of civilisation, it should be regarded rather as a peninsula of Asia, or as a portion of the great joint Eurasian continent; in regard to physical geography, fauna, and flora, it is difficult to draw a sharp line between Europe and Asia. On three sides Europe is bounded by sea—north by the Arctic Ocean, west by the Atlantic, south by the Mediterranean, Sea of Marmora, and Black Sea. But on the east the Urals, Ural River, and Caspian, though commonly assumed as the boundary towards Asia, do not mark a precise limit in respect of climate, flora, fauna, or physical conditions generally (see this discussed at ASIA); and actually the governments of Perm and Orenburg in Russia in Europe extend far beyond the Urals. Between the Caspian and the Black Sea, the ridge of the Caucasus seems a convenient dividing line between Europe and Asia, but the Manytch depression is really, from the geographical point of view, a more correct boundary; physically the whole Netherland of the Caucasus is part of Asia (q.v.). It is more curious that North Africa and South Europe are very closely related in many respects, geological and biological. It has even been said that the mountains of Auvergne divide northern France more sharply from Provence than the Mediterranean does southern Provence from Morocco and Algiers. But in current usage Europe is bounded on three sides by sea, and elsewhere by the Kara River, the Ural Mountains, Ural River, Caspian, and the Caucasus.

Various etymologies have been proposed for the name Europe. The old mythological one was that it was named from Europa (q.v.)—why, was not very clear. Another was that it came from Eurys,

the south-east wind. A third, given by Hermann, notes that the name is first applied, not to the whole continent, but (in the Homeric Hymn to Apollo) to the mainland of Thracæ, as distinguished from the Peloponnesus and the Greek islands, and suggests that Europe therefore means Broad Land (*eurus ops*, 'broad face'). Of late the tendency is to assume that the name was first given by Phœnician traders, and is from the word *Ērebh*, 'darkness'—i.e. the land of sunset, of the west. The area to which the name of Europe was applied grew with the extension of Greek geographical knowledge.

Europe has a total length from Cape St Vincent on the south-west to the mouth of the Kara River on the north-east of 3400 miles; and from North Cape in Norway to Cape Matapan, the southernmost point of Greece, a total breadth of 2400 miles. The continent of Europe, irrespective of islands, lies within 36° 20'—71° 10' N. lat., and 9° 30' W.—66° 30' E. long. Its area is estimated at 3,800,000 sq. m., being about a third of that of Africa, a fourth of that of America, and a fifth of that of Asia. It does not greatly exceed the total area of the United States. Its indented coast-line is more extensive in proportion to its size than that of any other great natural division of the globe, and is estimated to measure little less than 50,000 miles. This is caused by its great irregularity, and the number of deep inlets and gulfs which penetrate its surface. It has a population of nearly 330,000,000, which gives an average of nearly 87 for every square mile.

The body of the European continent divides itself naturally into two great portions—the great plain in the north-east, and the highlands from near the centre towards the south-west, the mountainous peninsula of Scandinavia lying apart from either. (See the accompanying physical map of Europe.) The plain occupies about two-thirds (2,500,000 sq. m.) of the entire extent of the continent. It reaches from the eastern boundary of Europe, north to the shores of the Arctic Ocean, south to the Caucasus and the Black Sea, and westward over the whole extent of the continent; gradually, however, becoming narrower towards the west. In shape this plain resembles a triangle; its base rests on the eastern boundary, and it may be said to reach its apex on the shores of Holland. It separates the two mountain-systems of Europe—the Scandinavian system (highest summit 7566 feet) on the north, and on the south the system of southern Europe. The mass of the Alps, covering an area of nearly 100,000 sq. m., forms the centre of the mountain-system of southern and western Europe, and stretches down on four sides towards France, Germany, Hungary, and Italy; the highest summit being 15,732 feet. The other chief mountain-masses are the Carpathians (8343 feet) the Balkans (9750), the Apennines (9574), the Pyrenees (11,170), and the Sierra Nevada (11,660), and in Sicily, Etna (10,850). The highest inhabited spot in Europe is, since 1882, the observatory on Etna (9075 feet), nearly 1000 feet higher than the hospice of the Great St Bernard. See ALPS, APENNINES, BALKAN, CARPATHIANS, PYRENEES, &c.

Europe is surrounded by water on three sides. The White Sea comes in from the Arctic Ocean; the German Ocean and the Mediterranean from the Atlantic. The most important peninsulas are in the north Scandinavia, and in the south the Crimea, Turkey and Greece, Italy, and Spain. With the exception of Iceland, the islands cluster closely round the mainland, the chief being Great Britain and Ireland, Iceland, Nova Zembla, Sardinia, Corsica, and Crete (Candia). The lakes of Europe are small as compared with those of Africa or America, the largest being Ladoga and Onega in Russia, and Wener in Sweden. The Volga (1977

miles), the Danube (1740), the Ural (1450), the Don (1125), the Kama (1055), the Petchora (975), and the Rhine (765) are the largest rivers of Europe.

The details of the geography of Europe are given under the names of its several political divisions, and of its lakes, rivers, and mountains.

*Geology.*—The oldest rocks of Europe—viz. the Archean and Palaeozoic—occupy the most continuous area in the northern part of the continent. Thus, they extend over all the Scandinavian peninsula, Finland, and a considerable portion of northern Russia. In western Europe they are likewise well developed, as in the British Islands, which (if we except the midlands, and the eastern and south-eastern parts of England) may be said to be mainly composed of Archean and Palaeozoic rocks. Similar rocks cover extensive areas in Brittany, in central France, and in the Iberian peninsula. In central Europe they occur for the most part in sporadic areas of limited extent, which upon a geological map look like islands surrounded by younger strata than themselves. One of the largest of these areas is that which stretches from the north of France through the Ardennes and southern Belgium into Rhenish Prussia, Westphalia, and Nassau. Another considerable tract occupies most of Bohemia, and smaller areas are met with in most of the mountain-ranges of Germany and Austria-Hungary. Archean and Palaeozoic rocks likewise appear to form the nuclei of the Pyrenees, the Alps, and the Caucasus, while the Ural range is exclusively composed of such rocks. In the maritime regions of the Mediterranean, crystalline schists and Palaeozoic strata are sparingly met with, as in southern and eastern Spain, in Sardinia, and Corsica. Considerable tracts of schistose rocks, however, extend through Turkey, and appear in many of the islands of the Aegean Sea, as well as in southern Greece, southern Italy, &c. Having mentioned the main areas at which these oldest rocks appear at the surface, it is not necessary to refer to the distribution of the Mesozoic and Cainozoic strata, save in the most general terms. They are confined chiefly to the low grounds of the continent, although now and again, as in the Pyrenees, the Alps, and the Caucasus, they rise to great elevations. It may be added also that they enter into the composition of not a few other hilly regions, such as the Carpathians, the Apennines, the high grounds of Herzegovina, Albania, &c. Accumulations of Pleistocene and Recent age are met with alike in mountainous and lowland regions. They are developed most continuously in the low grounds of central Europe—extending from the borders of the North Sea across Germany far into Russia. They likewise form enormous tracts of flat land bordering on the Black Sea, the Sea of Azov, and the Caspian. The alluvial lands through which the great rivers of Europe flow belong to the same division of geological time, while the glacial deposits which form the under-soils throughout a large part of northern Europe, and which reappear in the mountain-valleys of more southern regions, are all likewise included amongst Pleistocene and Recent accumulations.

Geologists are not yet agreed as to the origin of the Archean rocks, and it is altogether premature, therefore, to speculate upon the physical conditions of Europe at the period of their formation. All we know for certain is that the earliest land-surfaces, of the former existence of which no doubt can be entertained, were composed of Archean rocks.

Leaving the Archean, we find that the next oldest strata are those which were accumulated during the Cambrian period, to which succeeded the Silurian, the Devonian and Old Red Sandstone, the Carboniferous, and the Permian periods—all

represented by great thicknesses of strata, which overspread wide regions.

Now, at the beginning of the Cambrian period, we have evidence to show that the primeval ridge which was subsequently to become the continent of Europe was still largely under water, the dry land being massed chiefly in the north. At that distant date a broad land-surface extended from the Outer Hebrides north-eastwards through Scandinavia, Finland, and northern Russia. How much farther north and north-west of the present limits of Europe that ancient land may have spread we cannot tell, but it probably occupied wide regions which are now submerged in the shallow waters of the Arctic Ocean. In the north of Scotland a large inland sea or lake existed in Cambrian times, and there is some evidence to suggest that similar lacustrine conditions may have obtained in the Welsh area at the beginning of the period. South of the northern land lay a shallow sea covering all middle and southern Europe. That sea, however, was dotted here and there with a few islands of Archean rocks, occupying the site of what are now some of the hills of middle Germany, such as the Riesengebirge, the Erzgebirge, the Fichtelgebirge, &c., and possibly some of the Archean districts of France and the Iberian peninsula.

The succeeding period was one of eminently marine conditions, the wide distribution of Silurian strata showing that, during the accumulation of these, enormous tracts of the present continent of Europe were overflowed by the sea. None of these deposits, however, is of truly oceanic origin. They appear for the most part to have been laid down in shallow seas, which here and there may have been moderately deep. During the formation of the Lower Silurian the whole of the British area, with the exception perhaps of some of the Archean tracts of the north-west, seems to have been under water. The submergence had commenced in Cambrian times, and was continued up to the close of the Lower Silurian period. During this long-continued period of submergence volcanic activity manifested itself at various points—Great Britain and Ireland being represented at that time by groups of volcanic islands, scattered over the site of what is now Wales, and extending westward into the Irish region, and northward into the districts of Cumberland and south Ayrshire. Towards the close of the Lower Silurian period considerable earth-movements took place, which had the effect of increasing the amount of dry land, the most continuous mass or masses of which still occupied the northern and north-western part of the continent. In the beginning of Upper Silurian times a broad sea covered the major portion of middle and probably all southern Europe. Numerous islands, however, would seem to have existed in such regions as Wales, the various tracts of older Palaeozoic and Archean rocks of south Germany, &c. Many of these islands were partially, and some entirely, submerged before the close of Silurian times.

The next great period—that, namely, which witnessed the accumulation of the Devonian and Old Red Sandstone strata—was in some respects strongly contrasted to the preceding period. The Silurian rocks, as already mentioned, are eminently marine. The Old Red Sandstones, on the other hand, appear to have been accumulated chiefly in great lakes or inland seas, and they betoken therefore the former existence of extensive lands, while the contemporaneous Devonian strata are of marine origin. Towards the close of the Upper Silurian period, then, we know that considerable upheavals ensued in western and north-western Europe, and wide stretches of the Silurian seabottom were converted into dry land. The geo-

graphical distribution of the Devonian in Europe, and the relation of that system to the Silurian, show that the Devonian sea did not cover so broad an expanse as that of the Upper Silurian. The sea had shallowed, and the area of dry land had increased, when the Devonian strata began to accumulate. In trying to realise the conditions that obtained during the formation of the Devonian and Old Red Sandstone, we may picture to ourselves a time when the Atlantic extended eastwards over the south of England and the north-east of France, and occupied the major portion of central Europe, sweeping north-east into Russia, and how much farther we cannot tell. North of that sea stretched a wide land-surface, in the hollows of which lay great lakes or inland seas, which seem now and again to have had communication with the open ocean. It was in these lakes that the Old Red Sandstone was accumulated, while the Devonian or marine rocks were formed in the wide waters lying to the south. Submarine volcanoes were active at that time in Germany; and similarly in Scotland numerous volcanoes existed, such as those of the Sidlaw Hills and the Cheviots.

The Carboniferous system contains the record of a long and complex series of geographical changes, but the chief points of importance in the present rapid review may be very briefly summed up. In the earlier part of the period marine conditions prevailed. Thus, we find evidence to show that the sea extended farther north than it did during the preceding Devonian period. During the formation of the mountain-limestone, a deep sea covered the major portion of Ireland and England, but shallowed off as it entered the Scottish area. A few rocky islets were all that represented Ireland and England at that time. Passing eastwards, the Carboniferous sea appears to have covered the low grounds of middle Europe and enormous tracts in Russia. The deepest part of the sea lay over the Anglo-Hibernian and Franco-Belgian areas; towards the east it became shallower. Probably the same sea swept over all southern Europe, but many islands may have diversified its surface, as in Brittany and central France, in Spain and Portugal, and in the various areas of older Palaeozoic and Archæan rocks in central and south-east Europe. In the later stages of the Carboniferous period, the limits of the sea were much circumscribed, and wide continental conditions supervened. Enormous marshes, jungles, and forests now overspread the newly-formed lands. Another feature of the Carboniferous was the great number of volcanoes—submarine and subaerial—which were particularly abundant in Scotland, especially during the earlier stages of the period.

The rocks of the Permian period seem to have been deposited chiefly in closed basins. When, owing to the movement of elevation or upheaval which took place in late Carboniferous times, the carboniferous limestone sea had been drained away from extensive areas in central Europe, wide stretches of sea still covered certain considerable tracts. These, however, as time went on, were eventually cut off from the main ocean and converted into great salt lakes. Such inland seas overspread much of the low-lying tracts of Britain and middle Germany, and they also extended over a broad space in the north-east of Russia. It was in these seas that the Permian strata were accumulated. The period, it may be added, was marked by the reappearance of volcanic action in Scotland and Germany.

So far, then, as our present knowledge goes, that part of the European continent which was the earliest to be evolved lay towards the north-west and north. All through the Palaeozoic era a land-surface would seem to have endured in that direc-

tion—a land-surface from the denudation or wearing down of which the marine sedimentary formations of the bordering regions were derived. But, when we reflect on the great thickness and horizontal extent of those sediments, we can hardly doubt that the primeval land must have had a much wider range towards the north and north-west than is the case with modern Europe. The lands from which the older Palaeozoic marine sediments of the British Islands and Scandinavia were obtained must, for the most part, be now submerged. In later Palaeozoic times land began to extend in the Spanish peninsula, northern France, and middle Europe, the denudation of which doubtless furnished materials for the elaboration of the contemporaneous strata of those regions. Southern Europe is so largely composed of Mesozoic and Cainozoic rocks that we can say very little as to the condition of that area in Palaeozoic times, but the probabilities are that it continued for the most part under marine conditions. In few words, then, we may conclude that, while after Archæan times dry land prevailed in the north and north-west, marine conditions predominated farther south. Ever and anon, however, the sea vanished from wide regions in central Europe, and was replaced by terrestrial and lacustrine conditions. Further, as none of the Palaeozoic marine strata indicates a deep ocean, but all consist for the most part of accumulations formed at moderate depths, it follows that there must have been general subsidence of our area to allow of their successive deposition—a subsidence, however, which was frequently interrupted by long pauses, and sometimes by movements in the opposite direction.

The first period of the Mesozoic era—viz. the Triassic—was characterised by much the same kind of conditions as obtained towards the close of Palaeozoic times. A large inland sea then covered a considerable portion of England, and seems to have extended north into the south of Scotland, and across the area of the Irish Sea into the north-east of Ireland. Another inland sea extended westward from the Thuringerwald across the Vosges into France, and stretched northwards from the confines of Switzerland over what are now the low grounds of Holland and northern Germany. In this ancient sea the Harz Mountains formed a rocky island. While terrestrial and lacustrine conditions thus obtained in central and northern Europe, an open sea existed in the more southerly regions of the continent. Towards the close of the period submergence ensued in the English and German areas, and the salt lakes became connected with the open sea.

During the Jurassic period the regions now occupied in Britain and Ireland by the older rocks appear to have been chiefly dry land. Scotland and Ireland, for the most part, stood above the sea-level, while nearly all England was under water—the hills of Cumberland and Westmorland, the Pennine chain, Wales, the heights of Devon and Cornwall, and a ridge of Palaeozoic rocks which underlies London being the chief lands in south Britain. The same sea overflowed an extensive portion of what is now the continent. The older rocks in the north-west and north-east of France, and the central plateau of the same country, formed dry land; all the rest of that country was submerged. In like manner the sea covered much of eastern Spain. In middle Europe it overflowed nearly all the low grounds of north Germany, and extended far east into the heart of Russia. It occupied the site of the Jura Mountains, and passed eastward into Bohemia, while on the south side of the Alps it spread over a large part of Italy, extending eastwards so as to

submerge a broad area in Austria-Hungary and the Balkan peninsula. Thus the northern latitudes of Europe continued to be the site of the chief land-masses, what are now the central and southern portions of the continent being a great archipelago with numerous islands, large and small.

The Jurassic rocks, attaining as they do a thickness of several thousand feet, point to very considerable subsidence. The movement, however, was not continuous, but ever and anon was interrupted by pauses. Taken as a whole, the strata appear to have accumulated in a comparatively shallow sea, which, however, was sufficiently deep in places to allow of the growth, in clear water, of coral reefs.

Towards the close of the Jurassic period a movement of elevation ensued, which caused the sea to retreat from wide areas, and thus, when the Cretaceous period began, the British region was chiefly dry land. Middle Europe would seem also to have participated in this upward movement. Eventually, however, subsidence again ensued. Most of what are now the low grounds of Britain were submerged, the sea stretching eastwards over a vast region in middle Europe, as far as the slopes of the Urals. The deepest part of this sea, however, was in the west, and lay over England and northern France. Farther east, in what are now Saxony and Bohemia, the waters were shallow, and gradually became silted up. In the Mediterranean basin a wide open sea existed, covering large sections of eastern Spain and southern France, overflowing the site of the Jura Mountains, drowning most of the Alpine lands, the Italian peninsula, the eastern borders of the Adriatic, and Greece. In short, there are good grounds for believing that the Cretaceous Mediterranean was not only much broader than the present sea, but that it extended into Asia, overwhelming vast regions there, and communicated with the Indian Ocean.

Summing up what we know of the principal geographical changes that took place during the Mesozoic era, we are impressed with the fact that, all through those changes, a wide land-surface persisted in the north and north-west of the European area, just as was the case in Palaeozoic times. The highest grounds were the Urals and the uplands of Scandinavia and Britain. In middle Europe the Pyrenees and the Alps were as yet inconsiderable heights, the loftiest lands being those of the Harz, the Riesengebirge, and other regions of Palaeozoic and Archæan rocks. The lower parts of England and the great plains of central Europe were sometimes submerged in the waters of a more or less continuous sea; but ever and anon elevation ensued, and the sea was divided, as it were, into a series of great lakes. In the south of Europe a Mediterranean sea would appear to have endured all through the Mesozoic era—a Mediterranean of considerably greater extent, however, than the present. Thus we see that the main features of our continent were already clearly outlined before the close of the Cretaceous period. The continental area then, as now, consisted of a wide belt of high ground in the north, extending roughly from south-west to north-east; south of this, a vast stretch of low grounds, sweeping from west to east up to the foot of the Urals, and bounded on the south by an irregular zone of land having approximately the same trend; still farther south, the maritime tracts of the Mediterranean basin. During periods of depression the low grounds of central Europe were invaded by the sea, the irregular zone of land lying immediately to the south was partially submerged, and so converted into groups of islands,

and the Mediterranean at the same time extended north over many regions which are now dry land. It is in these two low-lying tracts, therefore, and the country immediately adjoining them, that the Mesozoic strata of Europe are chiefly developed.

A general movement of upheaval supervened at the close of the Cretaceous period, and the sea which, during that period, overflowed so much of middle Europe had largely disappeared before the beginning of Eocene times. The southern portions of the continent, however, were still mostly under water, while great bays and arms of the sea extended northwards now and again into central Europe. On to the close of the Miocene period, indeed, southern and south-eastern Europe consisted of a series of irregular straggling islands and peninsulas washed by the waters of a genial sea. Towards the close of early Cainozoic times, the Alps, which had hitherto been of small importance, were greatly upheaved, as were also the Pyrenees and the Carpathians. The floor of the Eocene sea in the Alpine region was ridged up for many thousands of feet, its deposits being folded, twisted, inverted, and metamorphosed. Another great elevation of the same area was effected after the Miocene period, the accumulations of that period now forming considerable mountains along the northern flanks of the Alpine chain. Notwithstanding these gigantic elevations in south-central Europe—perhaps in consequence of them—the low-lying tracts of what is now southern Europe continued to be largely submerged, and even the middle regions of the continent were now and again occupied by broad lakes which sometimes communicated with the sea. In Miocene times, for example, an arm of the Mediterranean extended up the Rhone valley, and stretched across the north of Switzerland to the basin of the Danube. After the elevation of the Miocene strata, these inland stretches of sea disappeared, but the Mediterranean still overflowed wider areas in southern Europe than it does in our day. Eventually, however, in late Pliocene times, the bed of that sea experienced considerable elevation, newer Pliocene strata occurring in Sicily up to a height of 3000 feet at least. It was probably at or about that period that the Black Sea and the Sea of Azov retreated from the wide low grounds of southern Russia, and that the inland seas and lakes of Austria-Hungary finally vanished.

The Cainozoic era is distinguished in Europe for its volcanic phenomena. The grandest eruptions were those of Oligocene times. To that date belong the basalts of Antrim, Mull, Skye, the Farøe Islands, and the older series of volcanic rocks in Iceland. These basalts speak to us of prodigious fissure eruptions, when molten rock welled up along the lines of great cracks in the earth's crust, flooding wide regions, and building up enormous plateaus, of which we now behold the merest fragments. The ancient volcanoes of central France, those of the Eifel country and many other places in Germany, and the volcanic rocks of Hungary are all of Cainozoic age; while, in the south of Europe, Etna, Vesuvius, and other Italian volcanoes date their origin to the later stages of the same great era.

Thus before the beginning of Pleistocene times all the main features of Europe had come into existence. Since the close of the Pliocene period there have been many great revolutions of climate; several very considerable oscillations of the sea-level have taken place, and the land has been subjected to powerful and long-continued erosion. But the greater contours of the surface which began to appear in Palaeozoic times, and which in Mesozoic times were more strongly pronounced, had been fully evolved by the close of the Pliocene

period. The most remarkable geographical changes which have taken place since then have been successive elevations and depressions, in consequence of which the area of the continent has been alternately increased and diminished. At a time well within the human period the British Islands have been united to themselves and the continent, and the dry land has extended north-west and north, so as to include Spitzbergen, the Farøe Islands, and perhaps Iceland. On the other hand, the British Islands have been within a recent period largely submerged.

The general conclusion, then, to which we are led by a review of the greater geographical changes through which the European continent has passed is simply this—that the substructure upon which all the sedimentary strata repose is of primeval antiquity. The dry lands are built up of rocks which have been accumulated over the surface of a great wrinkle of the earth's crust. There have been endless movements of elevation and depression, causing minor deformations, as it were, of that wrinkle, and inducing constant changes in the distribution of land and water; but no part of the continental ridge has ever been depressed to an abyssal depth. The ridge has endured through all geological time. We can see also that the land has been evolved according to a definite plan. Certain marked features begin to appear very early in Paleozoic times, and become more and more pronounced as the ages roll on. All the countless oscillations of level, all the myriad changes in the distribution of land and water, all the earthquake disturbances and volcanic eruptions—in a word, all the complex mutations to which the geological record bears witness—have had for their end the completion of one grand design.

*Climate, Flora, and Fauna.*—In respect of climate, by far the greater portion of the area of Europe belongs to the northern section of the temperate zone, though parts of Norway, Sweden, and Russia lie within the Arctic Circle. The southern parts of Spain, Sicily, and Greece are some twelve degrees from the northern tropic. See RAINFALL, TERRESTRIAL TEMPERATURE.

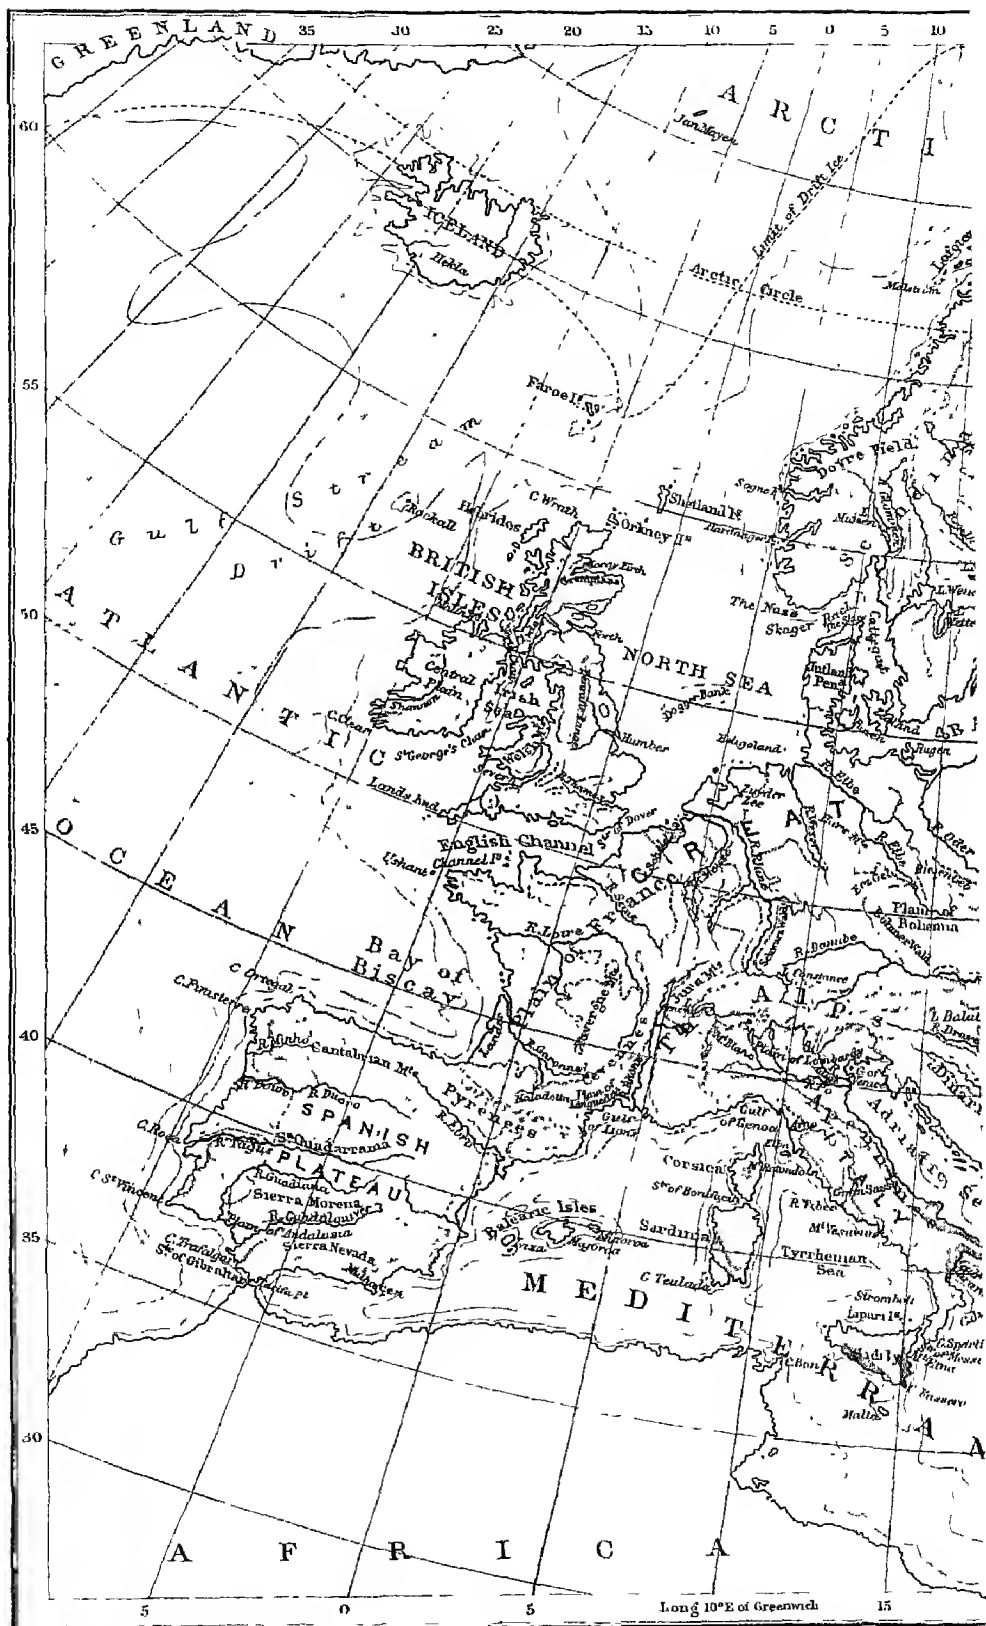

The natural history of Europe very much agrees with that of the corresponding latitudes of Asia. The natural history of the European countries on the Mediterranean Sea is very similar to that of Asia Minor and of North Africa. The natural history of the more northern regions of Europe resembles that of the great plains of Central Asia and Siberia. The most northern regions have the strictly arctic flora and fauna common in a great measure to all the arctic and sub-arctic regions; whilst the natural history of the most southern countries assumes a subtropical character.

The temperature of the western and northern parts of Europe being raised by the Gulf Stream and the winds from the great mass of dry and desert land in Africa above what is elsewhere found in similar latitudes, the flora and fauna exhibit a corresponding character, affected, however, by the great amount of moisture derived from the Atlantic Ocean, and also to a still greater degree by the comparative uniformity of temperature which the proximity of the ocean produces. The effect of the last-mentioned causes is so great that the northern limit of some plants is sooner reached on the shores of the Atlantic than in the more central parts of Europe, where the winters are much colder, and the average temperature of the year is lower. Of this the vine and maize are notable examples. Plants which require a mild winter will not grow in the north—and scarcely even in the centre of Europe—but they advance along the western coast under the influence of the maritime climate. Thus, the myrtle—although not indigenous—grows even

in the south of England. Amongst plants the date palm, and amongst animals a species of ape, are found in the south of Europe (the ape only on the Rock of Gibraltar); whilst some strictly African birds are frequent visitors, and many birds—as the cuckoo, swallow, &c.—are common to Europe and Africa, inhabitants in summer even of very northern regions, and returning in winter to the warm south.

Of the plants now most commonly associated in our thoughts with the southern countries of Europe, many have probably been introduced from Africa or from the East. This has probably been the case even with the myrtle, and certainly has been the case with the vine, the olive, the orange, lemon, &c., the fig, the peach, the almond, the apricot, &c. Some of the most extensively cultivated fruits are certainly indigenous to Europe, as the apple, pear, plum, and cherry, although even of these the first improved varieties may have been introduced from the earlier seats of civilisation in the East. Among the wild animals of Europe at the present day, the bison is still reckoned; and the ox existed at no very remote period in a truly wild state. The reindeer inhabits the extreme north of Europe; the elk, the stag, the fallow-deer, and the roebuck are found in more southern regions; the ibex or bouquetin exists on the high central mountains; two species of antelope—the chamois of the Alps, and the saiga of the Russian plains—connect the European fauna with the Asiatic and African. Of mammals peculiar to this part of the palaearctic region, the most notable are the chamois, the musk rat, the fallow-deer, the civet, ichneumon, and porcupine. Of carnivorous animals, the most worthy of notice are the bear, the wolf, the fox, and the lynx. On this head see the article GEOGRAPHICAL DISTRIBUTION, and the sections on animal and vegetable life in the articles on the various countries. The European seas afford valuable fisheries, particularly of herring and of cod in the north, and of tunny, anchovy, &c. in the Mediterranean.

*Ethnology.*—The European races belong in the main to the various branches of the great Aryan stock (see ARYANS, ETHNOLOGY), though in few European countries is there a pure race—the admixture of various stocks being in some cases very great and close. But, generally speaking, Celtic blood is most largely found in France (especially in Brittany, where a Celtic tongue is still spoken) and a part of Great Britain and Ireland; Teutonic peoples occupy Germany, Switzerland, Netherlands, part of Belgium, part of Austria, Denmark, Norway and Sweden, Iceland, and Great Britain. Slavonic races are found in Austria, Prussia, the Balkan peninsula, and Russia (see SLAVS). Romanic language and blood are prominent in Italy, France, Spain and Portugal, and Roumania. The Greeks belong to the same Greco-Italian branch of the Aryans as the Italians. Non-Aryan peoples are the Finns, Lapps, and Samoyedes of the north and north-east, various Turanian tribes in the east of Russia, the Hungarians and the Turks, and the Basques of the Pyrenees; and a strong element of pre-Aryan blood is also to be traced in other parts of western Europe, as in Ireland and Britain. The most obvious method of classifying races is language. By this test, some 105,000,000 Europeans are Teutonic (German, English, Dutch, Flemish, Swedish, Norwegian, Danish); 95,000,000 Slavs (Russian, Polish, Czech, Slovak, Serb, Croat, Slovenian, Bulgarian); 100,000,000 Romance-speaking (French, Italian, Spanish, Portuguese, Romanian, Walloon, Rhetian); 3,000,000 Letts and Lithuanians; 5,250,000 Greeks and Albanians; 3,600,000 Celtic (Welsh, Breton, Irish, Gaelic,

Manx); 1,050,000 Armenians, Ossetians, and Gypsies. Some 18,000,000 are non-Aryan (Magyars, Finns, Ugrians, Tartars, Turks, Kalmucks, Basques, Circassians, &c., and Maltese). Upwards of fifty languages are spoken in Europe. But language is by no means a sure test of race; thus, the Normans quickly took to speaking the Romance tongue of their Romanised Gallic subjects, the French—who, Celts, with a strong infusion of Frankish-Germanic blood, and a smaller infusion of Italic blood, spoke a modified Latin tongue.

Many parts of the German-speaking area are mainly Wendish or Prussian (Slavonic) blood. The Bulgarians, speaking a Slavonic tongue, are originally Ugro-Finnic. Fuller information must be sought in the articles on the various races and countries.

*Political Divisions.*—The following table gives a comparative view of the states of Europe, their areas, and populations. The populations are given according to the most recent censuses or estimates in 1889.

| STATES.                           | FORM OF GOVERNMENT.                                       | Extent<br>in English<br>square miles. | Population. | Number of<br>inhab. per<br>Eng. sq. m. |
|-----------------------------------|-----------------------------------------------------------|---------------------------------------|-------------|----------------------------------------|
| Andorra .....                     | Republic, with a sovereign council .....                  | 175                                   | 0,000       | 34                                     |
| Austria-Hungary .....             | Limited monarchy, two chambers .....                      | 240,456                               | 40,848,215  | 167                                    |
| Bosnia, Herzegovina, &c. ....     | Occupied by Austria .....                                 | 23,170                                | 1,504,091   | 65                                     |
| Belgium .....                     | Limited monarchy, two chambers .....                      | 11,373                                | 5,974,748   | 520                                    |
| Bulgaria & Eastern Roumelia ..... | Principality and autonomous province (under Turkey) ..... | 38,560                                | 3,154,375   | 82                                     |
| Denmark .....                     | Limited monarchy, two chambers .....                      | 14,124                                | 1,080,250   | 140                                    |
| France .....                      | Republic, two chambers .....                              | 204,692                               | 38,218,903  | 187                                    |
| Germany .....                     | Limited monarchy, two chambers .....                      | 211,140                               | 40,855,704  | 221                                    |
| Great Britain and Ireland .....   | Limited monarchy, two houses of parliament .....          | 120,832                               | 37,453,574  | 310                                    |
| Greece .....                      | Limited monarchy, one chamber .....                       | 25,014                                | 1,070,453   | 79                                     |
| Italy .....                       | Limited monarchy, two chambers .....                      | 114,410                               | 30,200,008  | 264                                    |
| Liechtenstein .....               | Principality, one chamber .....                           | 70                                    | 9,124       | 130                                    |
| Luxemburg .....                   | Grand-duchy (connected with Netherlands) .....            | 908                                   | 213,283     | 213                                    |
| Mouaco .....                      | Principality .....                                        | 8                                     | 13,304      | 1003                                   |
| Montenegro .....                  | Principality, limited sovereignty .....                   | 3,030                                 | 280,000     | 65                                     |
| Netherlands .....                 | Limited monarchy, two chambers .....                      | 12,648                                | 4,450,370   | 352                                    |
| Portugal .....                    | Limited monarchy, two chambers .....                      | 30,023                                | 4,708,178   | 131                                    |
| Roumania .....                    | Kingdom, two chambers .....                               | 48,307                                | 5,500,000   | 113                                    |
| Russia (in Europe) .....          | Absolute monarchy .....                                   | 2,095,504                             | 88,205,853  | 42                                     |
| San Marino .....                  | Republic, sovereign council .....                         | 82                                    | 8,000       | 250                                    |
| Serbia .....                      | Kingdom, two chambers .....                               | 18,750                                | 2,013,090   | 107                                    |
| Spain .....                       | Limited monarchy, two chambers .....                      | 197,670                               | 17,358,404  | 83                                     |
| Sweden and Norway .....           | Limited monarchy, two chambers for each country .....     | 293,848                               | 0,676,189   | 23                                     |
| Switzerland .....                 | Republican confederation, federal diet .....              | 15,892                                | 2,657,527   | 189                                    |
| Turkey (in Europe) .....          | Absolute sovereignty .....                                | 98,850                                | 4,700,000   | 75                                     |

*Religion.*—Europe is practically a region of monotheists: though there are Buddhist Kalmucks in South Russia, and Pagans amongst the Lapps, Finns, Samoyedes, and Tcheremisses. The Turks, some Russian Tartars, many Albanians, and some Slavs are Mohammedans (6,600,000), and there are nearly 7,000,000 Jews; but the bulk of Europeans are professing Christians. The Catholic Church may number some 156,600,000 adherents, the Greek Church 80,000,000, while the various Protestant communions number about 76,000,000.

*Historical Geography.*—The historical geography of the parts of Europe known in the oldest times is treated in the articles *ROME*, *BYZANTINE EMPIRE*, *GREECE*, &c. In the articles on the various countries of Europe (*FRANCE*, *GERMANY*, *AUSTRIA*, &c.) will be found detailed accounts of the origin and development of the several nations and countries; or in some cases (*BURGUNDY*, *POLAND*) of their gradual disappearance as separate states. In this place it seems desirable to give a sketch of some of the most notable changes in the political distribution and national divisions in the European area since the fall of the Roman empire, and to indicate the outstanding features of the political geography of Europe at the four important periods illustrated in the accompanying historical maps.

On the death of the Emperor Theodosius (395), the Roman empire was finally divided into two parts—the Latin empire, or Empire of the West, the capital of which was Rome; and the Greek empire, or Empire of the East, the capital of which was Constantinople. The Latin empire consisted of six dioceses—Italy, Gaul, Britain, Spain, Western Illyricum, and Africa; the Greek empire consisted of seven dioceses—the East, Egypt, Asia, Pontus, Thrace, Macedonia, and Dacia. In some of these dioceses may be traced the outlines of modern European countries.

Beyond the pale of the organised society of the Roman world lay a great barbaric society, divided into two parts—the German or Teutonic half

geographically adjoining the Western empire, and the Slavonic or Scythian half adjoining the Eastern empire. The German barbarians were divided into a number of tribes and nations—Goths, Burgundians, Alemanni, Vandals, Longobards, Franks, Angles, Saxons, &c. Farther away were the nomadic Alans. The Slavs, the ancestors of the modern Russians, Poles, and others, had their seats still farther east, and took less share in the events of mediæval history. In the destruction which preceded the resurrection of modern European society, it was chiefly the western or Latin half of the Roman empire that was involved, and the destruction was effected by the irruption chiefly of German nations; it is mainly the Germanic peoples who have created the modern nations of Europe. Amongst the Germanic peoples the Goths were most prominent (see *GOTHS*). The Gothic tribes were located, at the period when the movement began, in the extensive tract between the Vistula, the Danube, the Black Sea, and the Don, and were divided into Visigoths or Western Goths, and Ostrogoths or Eastern Goths.

The determining cause of the precipitation of the German races on the Latin empire was, it is well known, the sudden invasion of Europe (375 A.D.) by the Turanian or Ugrian nation of the Huns. Their movement was perhaps ultimately due to the gradual desiccation of the plateaus of Central Asia (see *ASIA*). Subduing the Slavonic region of Europe, and establishing there a Hunnish empire, which superseded that of its previous conquerors the Goths, these fearful Asiatic invaders produced a violent agitation among the Germanic peoples, and pressed them westward—Goths, Vandals, Burgundians, Suevi, Alemanni, Franks, Angles, and Saxons, all together. The agitations produced in Europe by the Huns, and by the consequent irruptions of the Germanic nations, sometimes in confederacy, and sometimes singly, into the provinces of the Western empire,

were protracted over a whole century. It will be sufficient here to mention generally that the diocese of Gaul was overrun chiefly by Visigoths, Burgundians, and Franks; Spain, by Vandals, Suevi, and Visigoths; Africa, by Vandals crossing over from Spain; in Italy, successive invasions had left among the feeble native Italians a deposit of Visigoths, Vandals, Huns, &c.; Britain, abandoned by its Roman garrison as early as 410, had become a prey to the Angles and Saxons.

As soon as this intermixture of the two societies—the Roman or civilised, and the Germanic or barbarian—had taken place, they began to act upon each other. Modern society, in short, is the perfected result of the incorporation of Roman with barbaric society; and it derives ingredients from both. From the barbarians were derived the love of personal liberty and the sense of individual independence. From the Romans, on the other hand, were derived the forms of a regular and long-established civilisation. But more efficient still, as a means of acting on the barbarian conquerors, was the great institute of the Christian Church.

In the 6th century the Franks occupied northern France and part of central Germany; the West Goths, France south of the Loire; Burgundians, the valleys of the Rhone and the Saone and various adjoining territories; while the West Goths were dominant over most of Spain, the Suevi holding the rest. The Thuringians were established in Thuringia; the Saxons in the large territory between the Menso in the west and the Oder in the east; the Danes and other Scandinavians in the region they still hold. The Ostrogoths held southern Europe from the Burgundian borders to the Danube, and the whole of Italy—which, however, in the latter part of the century, was occupied by the Lombards (see ITALY). The Slavonic Czechs were already in Bohemia; and the Bulgarians were between the Dnieper and the Danube.

In the latter part of the 8th century (see the first of the historical maps) the Frankish empire of Charlemagne extended from the Ebro to the Elbe, and from the North Sea to Rome, the Franks having conquered both the Goths of France and the Burgundians. The Frankish empire was repeatedly divided and reunited; but ultimately the two great divisions of Neustria (the kingdom of the West Franks) and Austria (the kingdom of the East Franks—Franconia, and not at all corresponding to what was later known as Austria) became the nuclei of the kingdoms and nations of France and of Germany.

In what is now Hungary were the Avars; while to the east of the northern portion of the Frankish realm was the region of Slavonia, including Bohemians, Poles, and other Slavic peoples. East of them again were that peculiar people the Khazari or Chazars (q.v.), belonging to the Finnic stock. Of the Gothic power in Spain nought was left but the little kingdom of Asturias; the rest formed the Moslem sultanate of Cordova, the Mohammedans having established themselves in Spain in 711. Most of England and part of Scotland was now occupied by the English or Anglo-Saxons. The Eastern empire had greatly shrunk.

In the 12th century (see Map II.) the kingdom of the East Franks had become the representative and successor of the Western empire, and, as the Germanic or Holy Roman empire, extended from the North Sea to the States of the Church, by this time the dominion of the popes. In the empire were the dukedoms or territories of Lotharingia or Lorraine, Franconia, Swabia, Bavaria, Thuringia, Bohemia, Austria, and Burgundy (the latter lately an independent kingdom). In South Italy was the Norman kingdom of Sicily. Henry II. of Anjou, king of England, was lord of Normandy,

Anjou, Brittany, and Aquitaine or Guyenne; the remainder of France being the kingdom of the successor of the kings of the West Franks. The power of the English kings was more fully established in Guyenne than in Anjou, and Guyenne remained much longer a part of the English dominions in France. England had established her power over the eastern part of Ireland. In Spain the Christian kingdoms of Leon, Castile, and Aragon were growing at the expense of the sultanate of Cordova. Poland and Russia were consolidated states, with heathen Prussians and Lithuanians for their northern neighbours. The Hungarians were in their present dominions; Bulgaria and Serbia still limited the decreasing Eastern empire on the north, while the latter was threatened on the east by the dreaded Turks.

At the Reformation in the 16th century Charles V. was not merely emperor in Germany, but king of Spain (whence the Moslems, long confined to Granada, had been driven), Sicily, and Naples, and ruler of the Netherlands and of the county of Burgundy. From the 15th century onwards, the imperial crown remained with the Hapsburgs. Ferdinand I., Archduke of Austria (and, after the abdication of his brother Charles V., emperor), obtained by marriage Silesia, Bohemia, and Hungary (as much of it as was not Turkish). These all became, like the archduchy and connected territories, hereditary domains of the House of Hapsburg; but while Bohemia, like the archduchy, was a fief of the empire, Hungary, with its dependences, was no part of the empire at all. From the middle of the century till near the end of the 17th, the Hapsburgs held the northwest part of Hungary; while the Turks, who had wiped out the Eastern empire, occupied the rest, a pasha ruling at Budin. Transylvania, Moldavia, and Wallachia were three tributary principalities. Dalmatia long fluctuated between Venice and Hungary. At the peace of Westphalia in 1648 (see Map III.), which closed the Thirty Years' War, the power of the empire was weakened, while that of France had increased, part of Alsace being given to France. By the 15th century France had acquired most of the territory of the old kingdom of Burgundy (between the Alps, the Saone, and the Mediterranean). It had absorbed the duchy of Burgundy (afterwards the French province of Burgundy or Bourgogne) in 1477; but it was not till 1674 that France seized the county of Burgundy (afterwards the French province of Franche Comté), and Strasbourg and its territory in 1681. Avignon had become a papal possession in 1348, and did not become French till 1791. The duchy of Savoy was becoming more and more an Italian power. Spain still held the Spanish Netherlands and great part of Italy. The Protestant Netherlands and Switzerland were become independent states. Sweden had acquired territories from Germany, Poland, and Russia, and was one of the great powers. She held not merely Finland, but all the lands around the Gulf of Riga, including Esthonia and most of Livonia. Sweden also held western Pomerania, Wismar, Bremen, and Verden, not as Swedish territory, but as fiefs of the empire; the ancient possessions of Denmark in the northern peninsula were acquired by Sweden in 1658. The duchy of Prussia had become independent of Poland in 1647. Poland, which early in the 16th century had been one of the most powerful states of Europe, holding under its sway a great part of Russia, now lost in power and territory, while Russia steadily grew. Turkey held part of the former dominions of the Eastern empire, the Austrian princes the rest. Venice was the most important native Italian power. Genoa held Corsica till 1798.

Before the outbreak of the French Revolution, Poland had ceased to exist as a state. Prussia had risen to greatness, and Russia had been greatly aggrandised. Sweden had fallen from her temporary hegemony of northern Europe. The Spanish Netherlands had belonged since 1713 to the House of Austria; French Bourbons held those parts of Italy that had been Spanish. The French Revolution began a series of changes in the distribution of power which culminated in the extension of Napoleon's empire over all Germany west of the Rhine, and great parts of northern Germany, the Netherlands, and most of Italy (see Map IV.); a portion being directly incorporated with the empire, another separately held by Napoleon himself as his kingdom of Italy, whilst his brother-in-law was king of Naples and his brother king of Spain. After the fall of the empire, France retired within her old limits; the minor German princes constituted their states in a loose confederation, and of this Austria assumed the presidency. Italy was parcelled out amongst numerous despotic princes, and the Venetian dominions became Austrian. The Netherlands became once more a kingdom, ultimately separated into Holland and Belgium.

The chief changes on the map of Europe since the middle of the 19th century have been the consolidation of Germany as an empire, under the headship of Prussia, and the restitution to it of Alsace-Lorraine; the retirement of Austria out of Germany, and her reorganisation as the Austro-Hungarian monarchy; the unification of Italy as a kingdom; and the gradual diminution of Turkish territory by the recognition of the independence of Roumania, Serbia, and Montenegro, and of the autonomy of Bulgaria.

As has been already said, the continuous history of the developments sketched or hinted at here must be sought in the articles on the various countries named; see, too, the *Historical Geography of Europe*, by E. G. Freeman (2 vols. 1881), his *General Sketch of European History* (2d ed. 1876), *Primer of History of Europe* (1876), and *Chief Points of European History* (1886); T. H. Dyer, *History of Modern Europe, 1453-1871* (2d ed. 5 vols. 1877); C. A. Fyfe, *A History of Modern Europe, 1702-1878* (3 vols. 1884-90); Lodge, *Modern Europe*, (1886); and the works of Gibbon and Hallam. For Geography and Statistics, see the relevant parts of Klünder and Reclus; 'Europe,' in Stanford's *Compendium of Geography* (1886); J. Geikie's *Prehistoric Europe* (1880); the annual *Almanach de Gotha* and *Statesman's Year-book*; and the works cited in the articles on the several countries in this work.

**Eurolas** (mod. *Iri* or *Vasilo*), the chief river of Laconia in Greece, rises in Arcadia, and flows through the valley between the ranges of Taygetus and Parnon, passing Sparta on the right, into the Laconian Gulf.

**Euryalē**, a genus of Water-lilies (Nymphaeaceae), closely allied to *Victoria* (q.v.), but with small flowers. The seeds and root-stock of *E. ferox* are eaten, and the plant has been cultivated in China from very early times.

**Eurydice**. See ORPHEUS.

**Eurysthenes**. See HERCULES.

**Eusebius** of Cæsarea, the father of ecclesiastical history, was born probably in Palestine about 264 A.D. He took the surname of Pamphilus from his friend Pamphilus, Bishop of Cæsarea, whom he faithfully attended for the two years (307-309) in which he suffered imprisonment during the persecution of Diocletian. He then went to Tyre, and afterwards to Egypt, where he was himself thrown into prison on account of his religion. He became Bishop of Cæsarea about 313, took a prominent part at the Council of Nice, and died in 340. Eusebius was the head of the semi-Arian or moderate party in the Council of Nice. That party was

averse to discussing the nature of the Trinity, and would have preferred the language of Scripture to that of theology in speaking about the Godhead. Eusebius held that the promise of everlasting life was to him that *believeth on the only-begotten Son*, not to him that *knows how He is begotten of the Father*. He was very reluctant to accept the term *homoousios*, devised by Athanasius to describe the equality of the Son with the Father, and retained the kindest feelings towards Arius after the views of the latter were condemned (see ARIUS). His moderation and other excellent qualities procured him the favour of Constantine, who declared that he was fit to be the bishop of almost the whole world. Eusebius has the reputation of being the most learned Father of the Church, after Origen and Jerome. His *Chronicon*, a history of the world down to 328 A.D., is valuable as containing extracts from many ancient writers whose works are no longer extant. His *Preparatio Evangelica*, a collection of such statements in old heathen authors as were fitted to make the mind regard the evidences of Christianity in a favourable light, also contains specimens of writings that no longer exist; its complement is the *Demonstratio Evangelica*, in twenty books, ten of which are extant, intended to convince the Jews of the truth of Christianity from the evidence of their own Scriptures. His most important work, however, is the *Ecclesiastical History*, in ten books. This relates the principal occurrences which took place in the Christian church till the year 324, and contains the results of his studies in numerous libraries, and even in the imperial archives, the Emperor Constantine having ordered, at Eusebius' request, an examination of all documents relative to the history of martyrs. One drawback of the work is that Eusebius, on principle, withholds all account of the wickedness and dissensions of Christians, inasmuch as he did not consider such stories for the edification of the church (see CHURCH HISTORY). Besides the foregoing works may be mentioned his *De Martyribus Palaestinae*, the treatises against Hierocles and Marcellus, the *Theophrasta* (discovered in 1839), and a panegyric of Constantine. The first edition of all Eusebius' works appeared at Basel in 1542; the last was commenced by Dindorf (Leip. 4 vols. 1867-71; unfinished).

**Eusebius** of Emesa was born at Edessa, and studied under Eusebius of Cæsarea, and at Alexandria and Antioch. Averse to all theological controversies, he declined the bishopric of Alexandria, vacant by the deposition of Athanasius. He was afterwards, however, appointed Bishop of Emesa, in Syria, but was twice driven away by his flock, who accused him of sorcery on account of his astronomical studies. He died at Antioch in 380. The homilies extant under his name are probably spurious.

**Eusebius** of Nicomedia, Patriarch of Constantinople, related to the Emperor Julian by the mother's side, was appointed Bishop of Beryta (Beyrout) in Syria, and afterwards of Nicomedia. He appeared as the defender of Arius at the Council of Nice, and afterwards placed himself at the head of the Arian party. He baptised the Emperor Constantine in 337, became Patriarch of Constantinople in 339, and died in 342. His enemies are our only sources of information as regards his character and opinions; yet, making the ordinary allowance for partisanship, there would seem to be sufficient reason for concluding that Eusebius was cunning and double-tongued when occasion required, and imperious and violent when he had power in his hands. Athanasius considered him not the disciple, but rather the teacher of Arius. See ARIUS.

**Euskarian**. See BASQUES.

**Eustachio**, BARTOLOMMEO, an Italian anatomist, who was physician-in-ordinary to the popes, and professor of Medicine in Rome, where he died in 1574. His name is indissolubly associated with anatomical science through his discoveries of the tube in the auditory apparatus (see EAR) and the rudimentary valve at the entrance of the inferior vena cava in the Heart (q.v.), which are called after him. These and other discoveries are recorded in his *Opuscula Anatomica* (Venice, 1564); his *Tabule Anatomice* were first edited by Lancisi in 1714.

**Eustathius**, a celebrated Greek commentator on Homer and the geographer Dionysius, was born at Constantinople. He was at first a monk, then a deacon and teacher of rhetoric in his native city; he was Archbishop of Thessalonica from 1160, and of Myra from 1174, and died at an advanced age some time posterior to 1185. Eustathius was profoundly versed in the ancient classic authors, and a man of prodigious acquirements; and the value of his quotations is heightened by the consideration that most of the works from which he extracts are no longer extant. His most important work is his commentary on Homer (1st ed. Rome, 1542-50), a rich mine of knowledge. Of a similar character is his commentary on Dionysius, first printed by Robert Stephens (Paris, 1547). Of his commentary on Pindar, only the *Proœmium* has come down to us (ed. by Schneidewin, Göttingen, 1837); a part of his theological and historical treatises, letters, &c. was published by Tafel in 1832.

**Eutaw Springs**, a small affluent of the Santee River, in South Carolina, near which the last serious battle in the American war of independence was fought, 8th September 1781. The Americans, under Greene, were repulsed after a desperate engagement; but the British, who had lost seven hundred men, were too much weakened to follow up their victory.

**Enter'pe** (i.e. 'she who delights'), one of the nine Muses (q.v.), the daughter of Zeus and Mnemosyne. She was the muse of lyric poetry, and is represented in ancient works of art with a flute in her hand.

**Euterpe**, a genus of Palms (q.v.). *E. oleracea*, the Palmeto or Cabbage-palm, is cultivated in Brazil (Para, &c.), both for its cabbage (the stem then serving for palisades), and for the sake of its fruit, which yields the basis of a refreshing drink. It is common in Central America.

**Euthanasia** (Gr.), an easy death, or a painless method of putting to death. The use of narcotics or other means for shortening life in disease has never become a subject of discussion in modern civilised countries, but it is often a very practical question how far such means are admissible for soothing the last hours of life, when the approach of death does not itself dull the consciousness and the sensibility to pain. It must be decided according to all the surrounding circumstances, medical and otherwise, in each individual case. As to the medical treatment to be employed for diminishing the sufferings of the dying, see Munk's *Euthanasia* (1887).

**Eutropius**, a Latin historian, concerning whom we only know that he filled the office of secretary to the Emperor Constantine, fought against the Persians under Julian, and died probably about 370 A.D. His *Breviarum Historie Romanæ*, giving a short narrative of Roman history from the foundation of the city to the time of the Emperor Valens (364 A.D.), is written in an extremely simple style, and appears to have been originally intended for the use of schools. It became very popular as the taste for original

investigation declined, and is either copied or followed by the early monkish annalists; it was twice translated into Greek, and was continued by others down to the 9th century. The History existed in three distinct forms at the revival of letters: the genuine work of Eutropius in ten books; the expanded editions of Paulus Diaconus and others; and a complete but largely interpolated copy contained in the *Historia Miscella* (edited by Eyssenhartd, Berlin, 1869). The *editio princeps*, printed at Rome in 1471, was from the impure text of Paul. The best modern editions are those of Tzschneke (Leip. 1796), of Grosse (Halle, 1813), and of Droysen (Berlin, 1879).

**Eutyches**, an archimandrite at Constantinople, from whom the Eutychian controversy took its name. His christological views were an exaggeration of those of Cyril of Alexandria. He held that after the incarnation of Christ everything human in him had become merged in his divine essence, and that Christ therefore had but *one nature*. His personal enemies Domnus of Antioch and Eusebius of Dorylæum denounced him to Flavian, Archbishop of Constantinople, and at a synod held there in 448 A.D. he was condemned as a Valentinian and Apollinarian heretic. An œcumenical council was, through the influence at court of Dioscurus, Cyril's successor at Alexandria, called to Ephesus for a renewed investigation of the matter in dispute. Leo, Bishop of Rome, at the critical moment reversed the policy of the Roman see (his predecessor Celestine had favoured Cyril), and wrote to Flavian his famous epistle, in which he set forth authoritatively the doctrine of the two natures and one person. The council met at Ephesus in August 449, under the presidency of Dioscurus, and, under fear of the fists of his fanatical monks, decided everything exactly as he wished. Eutyches was restored, and Flavian, Eusebius of Dorylæum, Theodoret, and Domnus of Antioch were deposed. On the death of Theodosius II. the government passed into the hands of his sister Pulcheria and her husband Marcian (28th July 450). The fourth œcumenical council met at Chalcedon (q.v.), 8th October 451, and, though the greater number of the five or six hundred bishops shared the views of Dioscurus, the imperial authority insured the acceptance of the formula of Leo, and the resolutions passed in 449 by the 'Robber Council' (*latrocinium Ephesinum*)—the name given it by Leo—were annulled, as having been extorted by fear. Eutyches, who had previously been a second time excommunicated by Anatolius, Patriarch of Constantinople, was removed from the neighbourhood of the capital by Marcian before the meeting of the council. Afterwards, on the advice of Leo, he was transported to some remote place, but his subsequent history is unknown. The Eutychian sect was from 452 put down by penal laws.

For the later history of the opponents of the decrees of Chalcedon, see GREEK CHURCH. See also Mansi, *Concilia*, vols. v. vi. vii.; Hefele's *Conciliengeschichte* (2d ed. 1873 et seq.); Martin, *Le Pseudo-Synode* (1875); Porry, *The Second Synod of Ephesus* (1881); Amelin, *S. Leone e l'Oriente* (Rome, 1882); Krüger, *Monophysitische Streitigkeiten* (1884); Harnack, *Dogmengeschichte*, vol. ii. (1888).

**Euxine**. See BLACK SEA.

**Evagrius**, surnamed SCITOLASTICUS, a church historian, was born at Epiphania in Syria in 530. An advocate by profession, he filled more than one administrative office under the Roman emperors. His *Ecclesiastical History*, covering the period from 431 to 594, forms a continuation of that of Eusebius. Although marred by the credulity of its age, it is on the whole fairly trustworthy. The best edition is that by Reading (Camb. 1720).

**Evander**, son of Hermes by an Arcadian nymph, called in Roman traditions Carmenta or Tiburtis. About sixty years before the Trojan war he is said to have led a Pelasgian colony from Pallantium, in Arcadia, to Italy, and to have landed on the banks of the Tiber, and near the foot of the Palatine Hill. Here he built a town, naming it Pallantium after the one in Arcadia. At a later period it was incorporated with Rome, and is falsely affirmed to have originated the names Palatinus and Palatium. He did much to introduce the habits of social life among his neighbours; he prescribed for them milder laws, and taught them, among other arts, those of music and writing. To him is also ascribed the introduction of the worship of the Lycean Pan, with that of Demeter, Poseidon, and other deities. Virgil represents him as being still alive when Æneas arrived in Latium after the sack of Troy, and as having sent him aid under his son Pallas, who fell by the hand of Turnus. Evander was worshipped both at Pallantium, in Arcadia, and at Rome.

**Evangelical** (lit., 'according to the gospel,' Gr. *euangelion*), a designation originally claimed by all Protestants, on the ground that their tenets were derived solely from the Evangel (in the widest sense)—i.e. the Bible, but in later times more particularly attached to the school that insists especially on the total depravity of unregenerate human nature, the necessity of conversion, the justification of the sinner by faith alone, the free offer of the gospel to all, and the plenary inspiration and exclusive authority of the Bible—views largely held by the Presbyterians of Scotland, the Nonconformists in England, and the corresponding churches in America and the British colonies. The adherents of this view within the Anglican communion are commonly called the 'Low Church.' In Germany, it is the special designation of the United church, as distinguished from the old Lutheran and Reformed churches, but the title has recently been assumed by the pietistic party within the Protestant churches, on the ground of their superior orthodoxy and absolute faith in Scripture. See CHURCH HISTORY, and ENGLAND (CHURCH OF).

**Evangelical Alliance**, an association of evangelical Christians belonging to various churches and countries, which, in the words of the circular issued by members of different churches in Scotland, 5th August 1845, and originating the movement for its formation, seeks 'to associate and concentrate the strength of an enlightened Protestantism against the encroachments of Popery and Puseyism, and to promote the interests of a scriptural Christianity.' At a meeting held at Liverpool, October 1-3 of that year, the scope of the association was extended to the means to be used for counteracting religious indifference. In 1846 (19th August-2d September) the first general conference was held in London under the presidency of Sir Culling Eardley, and was attended by 921 members from all parts of the world, representing as many as fifty different denominations. The association was instituted a free union, not of churches or sects, but of individual Christians, and the membership was confined to those holding 'the views commonly called evangelical' on the following nine points of doctrine—(1) the divine inspiration, authority, and sufficiency of Holy Scripture; (2) the right and duty of individual believers to exercise their judgment in the interpretation of Scripture; (3) one God and three Persons in the same; (4) human nature utterly corrupted by the fall; (5) the Son of God made man, His work of reconciliation for men's sins, and His mediatorial intercession and reign; (6) the

justification of the sinner by faith alone; (7) the work of the Holy Spirit in the sinner's conversion and sanctification; (8) the immortality of the soul, the resurrection of the body, the judgment of the human race by Jesus Christ, together with the eternal felicity of the righteous and punishment of the wicked; (9) the divine institution of the Christian ministry, and the obligatory and perpetual ordinance of baptism and the Lord's Supper. General conferences of the association have since been held at London (1851), Paris (1855), Berlin (1857), Geneva (1861), Amsterdam (1867), New York (1873), Basel (1879), and Copenhagen (1885). The Evangelical Alliance has done much to cultivate a spirit of unity among Protestants by the diffusion of exact knowledge of the condition and circumstances of their different churches, and has raised its voice effectively against slavery, profanity, and persecution. Its organ, *Evangelical Christendom, its State and Prospects*, is published in London monthly.

See the Reports of the Proceedings of the different conferences, especially of the preliminary meetings at Liverpool, October 1845 (Lond. 1845), and of the Constitutional Assembly in 1846 (508 pp. Lond. 1847); Massie, *The Evangelical Alliance, its Origin and Development* (Lond. 1847); and L. Bonnet, *L'Unité de l'Esprit par le Lien de la Paix: Lettres sur l'Alliance évangélique* (Paris, 1847).

**Evangelical Association**, a sect closely akin to the Methodists both in government and doctrine, founded by Jacob Albrecht or Albright, who was born in the state of Pennsylvania, 1st May 1759. Originally a Lutheran, he travelled through several states as an evangelist, and in 1800 organised his adherents in 'classes' after the Methodist manner. In 1807 he was appointed bishop, and down to his death, 18th May 1808, he was the leader of the sect, which in 1818 assumed the name Evangelical Association of North America. Since 1843 it has drawn many adherents from the English-speaking population. In 1887 its membership in the United States amounted to 132,508 (besides upwards of 6000 in Germany), with 1808 churches and 1069 itinerant and other preachers. The association publishes religious periodicals in large numbers. See Plitt, *Die Albrechtsleute* (Erlangen, 1877).

**Evangelical Union**, the name assumed by a religious body constituted in Scotland in 1843 by the Rev. James Morison of Kilmarnock (afterwards Dr Morison of Glasgow) and other three ministers, along with the congregations adhering to them. They had been separated from the United Secession Church on account of their doctrinal views, and were soon increased by a number of ministers and churches expelled from the Congregational Union of Scotland for holding similar doctrines. Their ecclesiastical system is a modified independency, ministers and representative delegates from the churches forming an annual conference, which has control over all denominational funds, as well as over home-mission work and the theological hall. Individual churches have different forms of internal government, some modelled on Presbyterianism, others on Independent usage. In 1889 there were 93 churches, and there are usually about 20 students attending the hall.

The doctrine of this body is expressed in a *Doctrinal Declaration*, issued in 1858 as an explanation of their faith, but not forming a fixed creed. They are Trinitarians, holding the divinity and substitutionary work of Christ, and the personality of the Holy Spirit. They also hold the Protestant doctrine of justification by faith, and in much their teaching corresponds to that of the Wesleyans. The distinctive elements in their creed, which led to the expulsion of their leaders from the bodies to which they belonged, are, in the words of their

'Basis of Union,' the 'love of God the Father in the gift and sacrifice of Jesus to all men everywhere, without distinction, exception, or respect of persons; of God the Son, in the gift and sacrifice of himself as a true propitiation for the sins of the world; and of God the Holy Spirit in his present and continuous work of applying to the souls of all men the provisions of divine grace.'

Believing in the freedom of the human will, they hold election to salvation to be conditional. The whole movement in which the body originated was a reaction from the Calvinistic doctrine of the Westminster Confession, in so far as that relates to predestination and to unconditional election and reprobation. They have been much identified with temperance reform, all their ministers requiring to be total abstainers from intoxicating drinks. Their doctrines have also been known (from Dr Morison's name) as the Morisonian heresy, or as Morisonianism. Their views have been much misrepresented, and for a full statement of these the reader is referred to the *Doctrinal Declaration of the Union*, and to the 'Basis of Union,' published yearly in the *Evangelical Union Annual*. See also the *History of the Evangelical Union*, by Dr Fergus Ferguson (1876).

**Evangelist** (Gr., 'a bringer of good tidings') denotes in the New Testament a preacher of the gospel. In Ephesians, iv. 11, 'evangelists' are distinguished on the one hand from the apostles and prophets, and on the other from the pastors and teachers, and hold a rank between both. They were not, like the latter, attached to individual congregations, but preached as *missionaries*, without having the authority of the apostles chosen as witnesses from the beginning by Jesus himself, or of the prophets, who testified from special inspiration. Philip and Timothy were such evangelists.—The term evangelist is also applied to the authors of the gospels (Gr. *euangelion*).

**Evans, Sir De Lacy**, general, was born in Ireland in 1787, and entering the army at twenty, saw three years' service in India and three in the Peninsula. In 1814 he was present at the capture of Washington, the attack on Baltimore, and the operations before New Orleans; in 1815 at Waterloo. An advanced Liberal, he sat for Rye in 1831–32, and for Westminster in 1833–65, with the exception of 1841–46. During 1835–37 he commanded the 'Spanish Legion,' 10,000 strong, for the young Queen Isabella against the Carlists, Evans' chief military exploits being the storm and capture of the Carlist lines of Ayetta, near St Sebastian, the storm and capture of Irun, and the capture of Oyarzun and Fontarabia. In 1854, on the declaration of war against Russia, he was appointed to command the second division of the army sent out to the Crimea, with the rank of lieutenant-general. His division was hotly engaged in the battle of the Alma, and Evans received a severe contusion of the shoulder. On 26th October, during the siege of Sebastopol, his division was attacked by a force of 6000 Russians. Evans met the enemy with great gallantry, and drove them back into the town. Invalided home in February 1855, he received the thanks of the House of Commons, and was created a G.C.B. He died 9th January 1870.

**Evans, Marian**. See **ELIOT, GEORGE**.

**Evans, Oliver**, an American inventor, born in Newport, Delaware, in 1755, made several notable improvements in flouring-mills, and is said to have invented the first steam-engine constructed on the high-pressure principle, the drawings and specifications of which he had sent to England in 1787 and 1795. In 1804 he completed a steam-dredging machine, which propelled itself on wheels to the river Schuylkill, a distance of a mile and a half,

and thus is considered the first land-carriage worked by steam in America. Evans also projected a railway between New York and Philadelphia, which his narrow means never allowed him to realise. He died in New York, 21st April 1819.

**Evanston**, a post-village of Illinois, on Lake Michigan, 12 miles N. of Chicago by rail, with a number of handsome residences, the Garrett Biblical Institute, a ladies' college, and the Northwestern University (Methodist). Pop. 4400.

**Evansville**, a port of entry and capital of Vanderburg county, Indiana, on the Ohio, 162 miles ESE. of St Louis by rail, with some fifty churches, a city hall, a court-house, a handsome post-office and custom-house, and a public library and art gallery. Coal and iron ore abound near by, and the town has a large number of mills, foundries, &c., besides a very considerable trade in tobacco, flour, and other staples. Pop. (1870) 21,830; (1880) 29,280.

**Evaporation**, or **VAPORISATION**, is the process by which a substance changes into the state of vapour. Some solids visibly evaporate—e.g. solid ice or snow gradually disappears though the temperature may be considerably below the freezing-point. The characteristic smell of certain metals, such as copper or iron, is supposed to be due to slow evaporation (see **SUBLIMATION**). The change of a liquid into the state of vapour may go on at all temperatures; but the rate of change is greater the higher the temperature is, until at last boiling—i.e. free evaporation—occurs (see **BOILING**). Slow vaporisation at temperatures below the ordinary boiling-point is used on a large scale for commercial purposes, when it is wished to crystallise out a substance which is held in solution. The rate of evaporation depends upon the amount of surface exposed. It depends, too, upon the pressure under which the vapour is developed, and thus evaporation goes on quickly if the vapour is removed as rapidly as it is formed, as is the case when wind blows over the surface of water or snow. The temperature at which boiling occurs also depends upon the pressure. This may readily be shown by boiling water in a glass flask until the steam has driven out most of the air. If the flask be now corked, and the source of heat be withdrawn, the boiling will cease. But if cold water be poured on the flask the boiling will recommence at once. This is due to the fact that the lowering of temperature causes condensation of some of the steam, and this lowers the vapour-pressure so far as to allow of free evaporation at the reduced temperature. At any given temperature evaporation ceases when a certain pressure of the vapour is arrived at, or, more correctly, a state of equilibrium is reached in which condensation balances evaporation. Condensation occurs at all pressures; but, if the proper pressure corresponding to the temperature is not reached, evaporation exceeds condensation; while, if the vapour-pressure is too great, condensation exceeds evaporation. The presence of another gas or vapour, such as ordinary air, has no effect upon the final value of the pressure which is attained; but the time taken to reach this final pressure does depend very greatly upon the presence of another gas. The time becomes greater as the amount of gas present increases. This state of equilibrium is disturbed at once by any variation of vapour-pressure or of temperature. A vapour is said to be *saturated* when it is in equilibrium in contact with its liquid.

A considerable amount of heat is absorbed in the process of evaporation. The amount depends upon the nature of the liquid, and also upon the temperature of evaporation. Regnault gives for 'total heat' of steam the formula  $606.5 + 0.305t$ , in

which  $t$  represents the temperature in degrees Centigrade. This means that a pound of saturated water-vapour at  $0^{\circ}\text{C}$ . gives out 606.5 units of heat when it condenses to water at  $0^{\circ}\text{C}$ ., while a pound at  $100^{\circ}\text{C}$ . would give out  $606.5 + 30.5$ —i.e. 637 units in changing to water at  $0^{\circ}\text{C}$ . The heat given out by a pound of saturated steam at any temperature when it condenses to water at the same temperature is called the *latent heat* of the steam at that temperature. The term is not a good one. It has reference to the fact that the heat which is required to evaporate a substance without change of temperature disappears so far as ordinary thermometric methods of determining its presence are concerned. If we take into account the variation of the specific heat of steam with temperature, Regnault's measurements of the total heat show that at  $0^{\circ}\text{C}$ . the latent heat is 605.5 units, at  $100^{\circ}\text{C}$ . it is 536.5 units, and at  $200^{\circ}\text{C}$ . it is 464.3 units. It thus decreases very rapidly with rise of temperature. It vanishes at the Critical Temperature (q.v.). The following is the latent heat of vaporisation of a few liquids at a pressure of one atmosphere: water, 536.0; alcohol, 202.4; ether, 90.5; bromine, 45.6. It is evident from these figures that the latent heat of vaporisation of water is relatively large. Were it not for this fact we might have rapid condensation of moisture in the atmosphere in consequence of a very small fall of temperature, and in this way destructive floods might be caused.

Practical use is frequently made of the latent heat of evaporation. Thus, in order to keep water cool it should be stored in vessels of porous earthenware. Some of the water passes through the pores, and evaporates at the outer surface. The latent heat necessary for this is drawn largely from the rest of the water, which is thus kept cool. It is even possible, as was first done by Sir John Leslie, to freeze water by this process. He put some water contained in a shallow earthenware vessel inside the receiver of an air-pump along with a dish of strong sulphuric acid. When the air was exhausted, rapid evaporation resulted; but the vapour was absorbed by the acid as quickly as it was formed, and thus the evaporation was kept up continuously, so that the remaining water was rapidly cooled down to the freezing-point.

The same principle is used in the formation of solid carbonic acid. A jet of liquid acid is allowed to escape from a strong vessel containing it. The outer parts of the jet evaporate, and in consequence the inner parts are solidified. Faraday actually froze mercury in a white-hot vessel by placing it in a little capsule which rested upon a mixture of solid carbonic acid and ether in the spheroidal state.

**Evarts**, WILLIAM MAXWELL, American lawyer and statesman, was born in Boston, 6th February 1818, graduated at Yale, and was admitted in 1841 to the New York bar, where he afterwards built up a notable practice, receiving in some cases \$25,000 or \$50,000 for an opinion. He was chief counsel for President Johnson in the impeachment trial in 1868, and filled the office of United States attorney-general to the end of Johnson's administration. He was United States counsel before the Alabama tribunal in 1872, and senior counsel for Henry Ward Beecher in 1875. In 1877–81 he was secretary of state, and he was elected to the United States senate for the term 1885–91.

**Eve**. See ADAM AND EVE.

**Evection**, a lunar inequality resulting from the combined effect of the irregularity of the motion of the perigee, and alternate increase and decrease of the eccentricity of the moon's orbit. See MOON.

**Evelyn**, JOHN, was born of wealthy parentage at Wotton, near Dorking, in Surrey, 31st October 1620. He was brought up by his maternal grandmother at Lewes (1625–37), then entered Balliol College, Oxford, having already been admitted at the Middle Temple, where, without a degree, he took up residence in 1640—the year of his father's death. Having witnessed Strafford's trial and execution, he resolved to absent himself 'from this ill face of things at home,' and so travelled for three months in Holland and Flanders. Back in London, 'studying a little, but dancing and fooling more,' in November 1642 he joined the king's army, only to leave it in three days' time, lest both himself and his brothers should be 'expos'd to ruin, without any advantage to his majestie;' and the Covenant being pressed on him, he travelled for four years in France, Italy, and Switzerland. At Paris in 1647 he married the ambassador's daughter, Mary Browne (1635–1709); and, returning for good to England in 1652, settled at Sayes Court, Deptford, the home he did so much to beautify. A thorough, if prudent royalist, he was much at court after the Restoration; acted on several public committees; during 1655–87 was one of the commissioners of the privy seal, during 1695–1703 treasurer of Greenwich Hospital; and from the first was a prominent member of the Royal Society. In 1694 he removed to his brother's at Wotton, and let Sayes Court to Admiral Benbow, who sublet it to Peter the Great (a 'right nasty' inmate). In 1699 he succeeded his brother; and, vigorous in intellect to the very last, he died at Wotton, 27th February 1706.

'Almost perfect' is Mr Wheatley's estimate of Evelyn, who was indeed a right worthy gentleman, as active and intelligent as he was honest and God-fearing, yet neither a Sage nor a Hero. His pen was a busy one, and dealt with a multitude of subjects—'architecture, painting, engraving, numismatics, history, politics, morals, education, agriculture, gardening, and commerce.' Of all his thirty-five works the chief are *Sculptura, or the History and Art of Chalcography and Engraving on Copper* (1662); *Sylva, or a Discourse of Forest-trees* (1664); and his delightful *Diary* (first published in 1818). It is to the last that Evelyn owes his present celebrity. Written by one who had accustomed himself to habits of close observation, it covers a period of more than seventy years—and these the most memorable in English history. It is, indeed, of inestimable value; Scott said that he had 'never seen a mine so rich.' See the Life by Henry B. Wheatley, prefixed to the sixth edition of the *Diary* (4 vols. 1879).

**Evening Primrose**. See CENOTHERA.

**Everest**, MOUNT, a peak of the Himalayas, in Nepal, and the highest ascertained point on the surface of the globe, rises to a height of 29,002 feet above the sea, in  $27^{\circ} 59' 12''$  N. lat., and  $86^{\circ} 58' 6''$  E. long. It was named in honour of Sir George Everest (1790–1866), surveyor-general of India, who completed in 1841 the great trigonometrical survey, and, having retired in 1843, published in 1847 his principal work, *An Account of the Measurement of two Sections of the Meridional Arc of India*. Everest was elected a Fellow of the Royal and other scientific societies, and was knighted in 1861.

**Everett**, ALEXANDER HILL, an American diplomatist and author, was born at Boston, Massachusetts, 19th March 1792, and in 1806, although the youngest of his class, graduated at Harvard with the highest honours. He was appointed minister at the Hague in 1818, at Madrid in 1825. Four years afterwards he returned to the United States, where he became proprietor and editor of the *North American Review* (1830–35), and also occupied a seat in the legislature of Massa-

chusetts. In the winter of 1840 he resided, as a confidential agent of the United States government, in the island of Cuba. Appointed commissioner to China in 1845, he died in Macao, June 28, 1847. Besides a volume of poems and several works on political subjects, he published two series of *Critical and Miscellaneous Essays* (Boston, 1845-47), probably the most interesting productions of his pen.—His younger brother, EDWARD EVERETT, was born at Dorchester, Massachusetts, 11th April 1794, and graduated at Harvard in 1811. At the age of nineteen he had already gained a high reputation as a Unitarian preacher in Boston. In 1815 he was elected professor of Greek in Harvard College; and to qualify himself more thoroughly for his work he visited Europe, where he resided for four years, and had a distinguished circle of acquaintance. Victor Cousin pronounced him 'one of the best Grecians he ever knew.' In 1820 Everett became editor of the *North American Review*, and in 1824 a member of the United States congress, sitting in the House of Representatives for ten years. In 1835-38 he was four times elected governor of Massachusetts; and in 1841-45 he was minister plenipotentiary at the court of St James. While in England he received the degree of D.C.L. from Oxford, and of LL.D. from Cambridge and Dublin. On his return to America he was elected president of Harvard College; on the decease of Daniel Webster he became secretary of state; and in 1853 he was returned to the United States senate. In 1860 he was nominated by the Constitutional Union party for the vice-presidency of the United States, receiving 39 electoral votes out of 303. He died 15th January 1865. Everett's principal works are *A Defence of Christianity* (1814); several fine poems; and his eloquent *Orations and Speeches* (4 vols. 1836-59), covering a wide range of subjects, and indicating a varied, vigorous, and flexible genius. His Memoir of Daniel Webster is prefixed to the collective edition of his friend's works (6 vols. Boston, 1852).

**Everglades**, a large shallow lake or marsh in southern Florida, inclosing thousands of islets, which are covered with dense thickets, and containing great numbers of alligators. From this district Florida is sometimes called the Everglade State.

**Evergreens** are those trees and shrubs of which the leaves do not fall off in autumn, but retain their freshness and verdure throughout the winter, and which may perform their functions during more than one year. Evergreen leaves are generally of thicker and firmer texture than the

white flowers with red berries. Evergreen leaves are sometimes very small, as in firs and heaths; sometimes pretty large, as in rhododendrons, laurels, magnolias, &c. Evergreens, both trees and shrubs, have always been much sought after by the landscape gardener, and for purposes of ornament and shelter. Some genera of plants consist exclusively, or nearly so, of evergreens, whilst in others they exist only as exceptional species. Most of the Coniferae are evergreens; and the sombre green of pines, firs, cypresses, &c. is a prevalent characteristic of northern scenery both in summer and winter; whilst the undiminished thickness of the foliage affords winter shelter to animals which could not so well exist in forests composed merely of deciduous trees. Holly and ivy are amongst the finest British evergreens; the box, privet, and different kinds of bay and laurel, rhododendron, phillyrea, myrtle, &c. are also familiar to every one. As instances of genera in which some species are evergreen and others deciduous may be mentioned Barberry and Cytisus. Great numbers have been added to the lists of evergreen trees and shrubs available for ornamenting British gardens and pleasure-grounds by the opening up of China and Japan within the last thirty years. No European country has a greater wealth of evergreen trees and shrubs at its command than Britain, the climate of which, chiefly owing to absence of extremes of cold and drought, meets the requirements of plants from the countries already named, and also in many cases those from New Zealand and the Cape of Good Hope. Evergreens in the United States include, besides many species of the smaller conifers, the Redwood and *Sequoia gigantea* of California.

**Everlasting Flower**, the popular name of certain plants, the flowers of which suffer little change of appearance in drying, and may be kept for years without much diminution of beauty. They are plants chiefly of the order Compositae, having their flowers (heads of flowers) surrounded with an involucre, the scales of which resemble the petals of a corolla, but are rigid, membranous, and contain little moisture. Some species of Cudweed (g.v.) (*Gnaphalium*) are often called everlasting flowers, and the other plants which bear the name belong to nearly allied genera, but particularly to *Helichrysum*, *Rhodanthe*, and *Acroclium*, which are mostly annuals and natives of Africa and Australia. *Helichrysum arenarium* is frequent on dry, sandy soils in many parts of Europe and the central latitudes of Asia. It is covered with a gray felted down, and has yellow flowers, which, when rubbed, emit a faint aromatic odour. It is often worn on the continent of Europe as an ornament in the hat, particularly by wagoners. *H. angustifolium* and *H. Stoechas*—shrubby species, natives of the south of Europe—have larger yellow flowers. Some of the species have a powerful and pleasant aromatic odour. Several kinds of everlasting flowers are frequently to be seen in our gardens; others, such as *Phaenocoma* and *Aphlexis*, natives of the Cape of Good Hope, are of shrubby habit, and choice and beautiful greenhouse plants. As an instance of everlasting flowers in other orders than Compositae

Everlasting Flower  
(*Helichrysum bracteatum*).

A, Ardisia; B, Holly (*Ilex*); C, Skimmia.

leaves of deciduous trees and shrubs. The habit most common among the larger-leaved forms is indicated in the figure—these three distinct and unrelated evergreens, Ardisia (*Primulaceae*), Holly (*Aquifoliaceae*), and Skimmia (*Rutaceae*), having not only the same type of leaf, but very similar small

may be mentioned the genus *Statice*; the coloured calyx in nearly all the numerous species of which it is composed is dry, membranous, and very persistent. The French call everlasting *Immortelles*, and often weave them into circular wreaths, which are placed beside recent graves, as emblems of immortality or of loving memory. A very extensive trade is now carried on by France, Germany, and Italy in growing and preserving everlasting flowers for exporting to Britain and America.

**Eversley**, a village of NE. Hampshire, 13 miles NE. of Basingstoke. Charles Kingsley was rector of the parish from 1842 till his death here on 23d January 1875, and he lies buried in the churchyard.

**Evesham**, a municipal borough of Worcester-shire, on the right bank of the navigable Avon, 15 miles SE. of Worcester. It lies in a beautiful and fertile vale, and the chief industry is market-gardening. There are a fine modern bridge, public gardens, water-works (1884), a 16th-century guild-hall, &c.; but the stately Benedictine abbey (709) is represented chiefly by a beautiful Perpendicular belfry (1533). Till 1867 Evesham returned two members to parliament, till 1885 one. Simon de Montfort was defeated here, 4th August 1265. Pop. (1851) 4605; (1881) 5112. See May's *History of Evesham* (1845).

**Eviction**, in Law, means the dispossession of one person by another having a better title of property in land. In Scotland, the term is applied also to dispossession of movables, although in England and the United States it is restricted to lands and tenements. As popularly employed, eviction generally means the forcible expulsion of a tenant from lands and houses. The technical legal terms for this process are Ejectment (q.v.) in England, and Removing (q.v.) in Scotland. The law of Ireland as regards evictions is in a different position from that of the rest of Great Britain, from the favour shown to tenants by the recent Irish Land Acts. A tenant's interest in the land can be attached by creditors other than his landlord, and the tenant be evicted for failure to pay his debts, or by foreclosure of mortgage; but the great majority of cases are cases of eviction by the landlord. This eviction proceeds upon the tenant's failure to perform some part of his contract of lease—in general, the agreement to pay rent at stated periods, or the obligation to remove voluntarily when the lease has expired. Under the recent statutes, no tenant in Ireland can be evicted for non-payment of rent unless he owes at least a year's rent. Where proceedings are taken with a view to have a tenant evicted from a holding for which a judicial rent has not been fixed, the tenant may apply to the court to fix a fair rent. If a tenant has been decided by the court to be entitled to compensation for improvements, he cannot be compelled by process of law to quit his holding until the amount due to him as compensation has been made good. After a landlord has obtained his judgment, six weeks must pass before he proceeds any further, in which time the tenant may pay the amount due, and thus stay the eviction. Before the passing of the Land Act of 1887, the eviction then took place if the tenant had failed to settle; and the evicted tenant had a right to redeem for six months, and during this time the landlord was liable to him for the crops on the land. It became a widely prevailing custom for landlords, in these circumstances, to reinstate the tenant immediately after his eviction, as caretaker of the holding. After the period of redemption had run out, this caretaker might again refuse possession of the land, and be again physically removed. If he paid the amount due to the landlord, he became tenant again. The Land Act of 1887 made

law such of the rules of this custom as were in favour of the tenant. With reference to holdings of not more than £100 a year of rental (and the greater number of Irish holdings are such), it enacted that, when a landlord had obtained judgment entitling him to evict for non-payment of rent, he should (instead of proceeding to evict the tenant as formerly) serve upon him an eviction notice. The notice informs the tenant that a decree for the recovery of the land for non-payment of rent has been obtained by the landlord; that any person entitled by law to redeem the said land must do so within six months from the service or posting of the notice, by paying to the landlord, or his agent, the sum specified in the notice as rent arrears and costs; and that on service or posting of the notice the person in possession of the land, to whom the notice is addressed, is deemed to be in possession as caretaker only, and not as tenant. A return of such notices filed in court is presented from time to time to parliament, and their number is often mistaken for the number of actual physical ejections from lands which take place in Ireland. But the tenant may redeem his right within six months, and meantime remains in possession of the land as caretaker. He cannot be removed as caretaker until a month after service of the notice, unless by special leave of the court. When a warrant has been applied for for his removal as caretaker, the justices may put a stay upon the issue of the warrant for a month or less, if they think that, by reason of the illness of the caretaker, or any other cause, the proceedings ought to be delayed.

**Evidence**. Evidence may be defined as the means of proving an unknown or disputed fact. In ordinary legal usage the term has two meanings which should be distinguished. In one it denotes testimony as to the existence of facts; in the other it denotes relevancy to an issue, as when it is said that 'hearsay is not evidence.' Evidence is divided into oral or parole evidence, or statements made by word of mouth by witnesses in court; and documentary evidence, the testimony derived from writing, or the use of any conventional symbols which, like letters, serve to express ideas. Real evidence is the testimony of things, as where foot-prints in a field give evidence that some one has been there. Another distinction is drawn between direct and circumstantial evidence. Direct evidence is the testimony of witnesses to what they have themselves observed or know of their own knowledge regarding the fact to be ascertained, as when A testifies that he saw B stab C with a knife. Circumstantial evidence is testimony given by witnesses to what they have observed or know regarding facts more or less remotely connected with the unknown or disputed fact, as when A testifies that he found upon B a blood-stained knife. The relative value of direct and circumstantial evidence as proof of fact has been much discussed. Direct testimony is generally esteemed the stronger; but witnesses may be mistaken, deceived, or deliberately false; while circumstances 'cannot lie,' and the conclusion forced upon the mind by an unbroken train of circumstances pointing in the same direction is often more forcible than positive direct testimony.

Instances may be found in which combinations of facts and circumstances are morally satisfactory as grounds of assurance and judgment, and, in many cases where a conviction has proceeded upon circumstantial evidence alone, the prisoner has afterwards confessed his guilt. A good example is the case of Courvoisier, the valet and murderer of Lord William Russell (1840). Here there was no direct testimony whatever to connect the accused with the crime, and there were circumstances designed by the accused to suggest that it was the

work of burglars. It was proved, however, that the prisoner had an opportunity of committing the crime, that some of the abstracted property had been concealed in his pantry, and that he personally had disposed of other portions of it. The evidence, besides, excluded the reasonable belief that any other than the prisoner was guilty, and upon these grounds he was convicted, and afterwards confessed. On the other hand there have been cases, happily rare, in which a miscarriage of justice, and the conviction of the innocent instead of the guilty, have resulted from a reliance by the jury upon circumstantial evidence. The most remarkable of these that has occurred in recent times arose out of a burglary committed at the rectory of Edlingham in 1879. Two burglars, one of whom shot at the rector, were seen on the night by the rector and another person. Two men were arrested and tried for the crime at Northumberland Assizes in 1879. Neither the rector nor the other person who had seen the burglars was able to identify the prisoners, and the defence was that the case for the prosecution was wholly one of mistaken identity. But a chisel found in the room where the crime was committed was traced to the possession of the prisoners; a piece of newspaper picked up in the same room was found to correspond with a piece in the coat of one of the prisoners; and footmarks found near the scene of the crime corresponded with those of the prisoners. The jury on this evidence found them guilty, and they were sentenced to penal servitude for life. They served in the convict settlement at Portsmouth for nine years; when, in 1888, the true burglars, two other men than those who had been convicted, confessed to the crime. Inquiries were made by the authorities, with the result that the men who had been convicted on the evidence of the chisel, the newspaper, and the footmarks, were set at liberty.

Judges and juries are not allowed by law to proceed upon their private knowledge of facts at issue before them, and must decide according to the evidence adduced. Of some facts, however, a judge takes 'judicial notice,' and these do not require to be proved by evidence. Such are all public acts of parliament, the proceedings and privileges of parliament, the course of proceeding and all rules of practice in force in the Supreme Court of Justice, the ordinary course of nature, natural and artificial divisions of time, the meaning of English words, and many other matters which judges are by statute specially directed to notice. Judges are also bound under the rules of law called presumptions to draw a certain inference from a certain fact unless the truth of such inference is disproved. A *presumptio juris et de jure* does not allow its inference to be disputed. For example, the law presumes that a minor is incapable of managing his own affairs; and, when a man is proved to be a minor, he will be held so incapable without regard to the question whether in truth he is so or not. A *presumptio juris* may be rebutted, as thus: the law presumes that when a woman is married, her husband is the father of her children; but evidence may be adduced to prove the contrary. A third kind of presumption has been distinguished, the *presumptio iudicis vel hominis*, but this is merely another name for an argument or inference of logic. With regard to disputed facts that are not matter of judicial notice or legal presumption the general rule is that he who affirms a fact must prove it; and the burden of proof lies in the first instance on the party against whom judgment would be pronounced in the absence of evidence on either side.

The general rule governing questions as to what facts may be proved in judicial proceedings is

that facts in issue (or those upon which the existence of the legal right in question depends) and facts relevant to the issue—i.e. those from which the facts in issue may be inferred—may be proved to the exclusion of all other facts. Facts collateral to the issue are not allowed to be proved—e.g. in a question whether A committed a crime, the fact that he formerly committed another crime of the same kind is held to be irrelevant, and not allowed to be proved. Hearsay evidence—i.e. testimony to the fact that a statement was made by a person not called as a witness—is similarly deemed to be irrelevant, the reason generally assigned being that the best evidence must be given. But the rule excluding hearsay suffers exceptions. Thus, voluntary confessions of crime and declarations by persons accused of crime are admitted as evidence against themselves; and declarations made by witnesses at the point of death, or in fear of death, are received as evidence against others. The opinion of a witness, as distinguished from his testimony to a fact, is generally held to be irrelevant; but the opinion of skilled persons or experts as to matters coming within their special province is admitted. Thus, in a question whether a man was sane when he made his will, the testimony of a witness to the fact that the deceased wrote his will in different coloured inks upon medicine labels would be deemed relevant, while the same witness's opinion that 'no sane man would make a will in that way' would be deemed irrelevant; but in a question whether A was poisoned, the opinion of medical men is admitted as to the effects of the poison of which A is said to have died. Evidence as to a person's character is deemed to be relevant in an inquiry regarding his conduct.

Admissible facts may be proved by documentary or by oral evidence. When the contents of documents are proved by the production of the document itself in court, the evidence is said to be primary. When copies are produced, the evidence is said to be secondary. As a general rule the documents themselves are necessary, as being the best evidence; but copies are accepted in certain settled cases—as where the original is in possession of the adverse party, who refuses to produce it; where it has been destroyed or lost; or where it is of such a nature as not to be easily movable, as in the case of a libel written on a wall. Public documents, such as the records of the realm, the acts of parliament, and the like, are proved by copies variously authenticated. When the law requires writing as proof of any proceeding or contract, oral evidence will not be admitted to alter or contradict such writing. Such evidence will, however, be received for the interpretation and construction of documents where they are obscure or couched in language used out of its ordinary sense.

The old rules which restricted or excluded the admissibility of a witness on the ground of religion, of interest, and of character have been gradually swept away by legislation. Objections of interest and character do not now affect the admissibility of witnesses, but are urged against their credibility when their testimony has been received. As a general rule all persons who are capable of giving rational evidence are admissible as witnesses. Extreme youth and mental infirmity will exclude if it is such as to prevent the witness from understanding questions or giving rational answers, or from knowing that he ought to speak the truth. In criminal cases the accused is not admissible as a witness, nor the husband or wife of the accused, except where he or she is the person injured by the crime. Some exceptions to the rule have been made by recent statutes—as e.g. the Criminal Law Amendment Act of 1885, which allows persons

accused of offences under this act and their husbands or wives to be competent witnesses. Thus, a man charged under the act with abduction of a girl under sixteen may give evidence himself, and call his wife to prove that at the time the crime was said to be committed he was not at the place where it was committed; while a man charged with assault with intent to ravish (which is not within the act) can neither testify himself nor adduce his wife's evidence at all. Witnesses are in the ordinary case examined in open court by word of mouth, after taking an oath to tell the truth. If any witness is unwilling to be sworn from conscientious motives, the judge may permit him to make a solemn Affirmation (q. v.). Any person who has made such declaration and wilfully and corruptly gives false evidence may be prosecuted and punished as if he had committed Perjury (q. v.). Witnesses are first examined by the party who calls them into court. After this examination-in-chief they are cross-examined on behalf of the opposite party, and then re-examined. Leading questions—i.e. questions which suggest their own answer—may be put in cross-examination, but not in the examination-in-chief. No witness is bound to answer any question if the answer would expose him to a criminal charge; but if the result of his answer would be to render him liable to a civil suit for debt or otherwise he must answer notwithstanding. Questions may be put in cross-examination to test the accuracy or credibility of the witness, and to shake his credit by injuring his character; but the judge may disallow questions which he considers to be vexatious and not relevant to the issue. Every witness may be examined as to whether he has ever made a different statement regarding the matter of his examination; and, if he denies, proof may be led to contradict him. Spouses cannot be compelled to disclose communications made to one another during the marriage. Confidential communications between parties to legal proceedings and their legal advisers are similarly protected. Medical men and clergymen, on the other hand, may probably be compelled to disclose communications made to them in professional confidence, although the point remains doubtful (see CONFIDENTIALITY). Except in cases of treason and perjury, the evidence of one witness is held sufficient by the law of England to support a conviction; but proof of circumstances to corroborate such witness is usual. The rule runs the other way in Scotland, where no libel can be proved by the unsupported testimony of a single witness; but, as one witness is held sufficient to prove each of a chain of connected facts, the practical effect of the two rules is the same in both countries. See Sir James Fitzjames Stephen's *Digest of the Law of Evidence* (5th ed. 1887), and Kirkpatrick's *Digest of the Scottish Law of Evidence* (2d ed. 1886).

In the United States, state laws prescribe the rules of evidence which govern the state courts, and, in the absence of congressional enactments, federal courts. The effect of recent acts of congress is that there is now no restriction as to the admission of testimony based upon the colour or nationality of the witness; and in general the party in interest both in civil and criminal cases may be a competent witness, subject to the general rule that a party is not compelled to criminate himself, nor shall his silence upon any question create a presumption against his innocence, and subject also to the general rule that a husband shall not be allowed to testify against his wife, nor the wife (unless the offence has been committed by the one against the other) against her husband. Where the evidence relates to the remedy, as in the proving of an instrument by subscribing witnesses,

state rules govern both in federal and state courts; hence the practice varies with the locality. Circumstantial evidence is admitted by courts with great reluctance, and in criminal cases, if not corroborated by the positive evidence of at least one witness, it must be of such a character as to be equivalent in weight of evidence to direct and positive evidence, and be entirely inconsistent with the innocence of the party accused.

A belief in God and in divine rewards and punishments, here or hereafter, for deeds done is essential to the admissibility of a witness; and this belief must have no reference to the punishment for perjury by human law; hence one having no belief in God cannot be a competent witness, and no form of oath which he declares to be binding upon his conscience cures this defect. The jury are the judges of the fact, and, as such, of the credibility of the witnesses; hence no jury in the United States is obliged to reject a statement of a witness because uncorroborated by positive testimony, either direct or circumstantial. The general rules as to relevancy; the relative value of written and oral evidence, and the control of the one by the other; and the taking of an oath or affirmation are to the same effect as those observed in England.—For the evidences of religion, see APOLOGETICS.

**Evil** may be generally defined as that which is opposed to the divine order of the universe. It requires only a superficial observation to perceive that there are many apparent exceptions to the pervading harmony and happiness of creation: there are convulsions in the physical world; there are suffering, decay, and death throughout the whole range of organic existence; and the appellation of Evil is commonly applied to such phenomena. In the face of the human consciousness, such phenomena appear to be infractions of the general order and good, and it pronounces them *evil*. Every form of religion testifies to the recognition of evil in the external world, and superstition in all its shapes mainly rests upon it.

But it is in the sphere of moral life alone that the conception of evil is most deep-seated—evil in human life and manners and history. There is in the moral consciousness of man a sense of violated order, of transgression of divine law, or what is called *sin*, which is *evil* in its essential form. This fact of evil is everywhere appealed to by the Christian religion; it is the aim of this religion to deliver men from its power and misery. Every ethical and judicial code is based upon its recognition, and is designed to protect human society from its injurious consequences.

The question of the *origin of evil* has been greatly discussed, and has received various answers. The simplest and most direct of these answers is that which maintains a double origin of things, or a system of *dualism*. This conception lies at the basis of many forms of religion; it may be said to be the fundamental conception of all mere nature-religions. Interpreting the obvious appearances of nature, these embody in divine personalities its contending manifestations of light and darkness, benignity and terror. The opposition of Ormuzd and Ahriman in the old Zoroastrian faith is one of the most conspicuous examples of this religious dualism. Manicheism, which spread so widely in the 4th and 5th centuries, and the Syrian gnosticism from which it sprang, though accounted amongst Christian heresies, are also historical illustrations of the same principle.

The dualistic theory of the origin of evil, however, could not maintain itself with the advance of speculation and the truer appreciation of Christian truth. It was at once a postulate of the cultivated reason and a dictate of divine revelation that the world proceeded from One absolutely

Divine Creator, holy and good, of whom, and through whom, and to whom are all things. It was necessary, therefore, to reconcile the appearance of evil with this fundamental admission.

The doctrine of the Fall, especially in the later form of development which connects it with the existence of a devil or evil spirit, tempting man in the shape of the serpent, was supposed to explain the appearance of evil in human history. Being tempted of the devil, man sinned, and so fell from his obedience to the divine law. This is the doctrine of orthodox Christian theology, and the answer which it gives to the inquiry, how sin came into the world. And many minds never think of carrying the inquiry further. It is clear, however, that this explanation of the historical origin of evil leaves the question of its real and absolute origin unsettled. The devil being assumed as the cause of man's sin, the further question arises, whence the devil? Is he an absolute personality? in which case we are landed in the old theory of dualism; or is he, according to the traditional Christian conception, a fallen angel? in which case the question just returns, whence the spring of evil in him? (See *DEVIL*.) There is no real explanation gained by this removal of the question; it is still the same difficulty—whence the origin of evil in the creation of an all-perfect Being, almighty as well as all-wise and good?

Speculation may please itself with ingenious answers to this question, but in truth it admits of no satisfactory solution. Some, for example, have argued that evil, like darkness or cold, is an indispensable element of alternation or contrast in human life. All individual reality is only the product of opposite forces working together. Character could only arise from the interaction of opposing ethical influences of good and evil. In nature we have attraction and repulsion, rest and motion, positive and negative electricity; why should it be different in the sphere of morals? Here, too, there must be polarity. Good can only exist in contradistinction to evil; the one no less than the other is necessary to constitute the drama of human life and history. Others, again, have argued that evil is the result of what is called metaphysical imperfection. God alone can be perfectly good. The creature in its very nature is limited, defective; and evil is nothing else than the evidence of this limitation in man. It is not something real or positive, but only a privation. It is in morals what cold and darkness are in physics, a pure negation. Thus have argued such profound thinkers as Augustine and Leibnitz. But it requires but little penetration to see that such arguments, however ingenious and so far well founded, do not meet the essential difficulty of the problem. If evil be, according to such views, a necessary element of human life, in the one case in order to develop its activity, in the other case as clinging to its creaturely limitations, then plainly it is not, in the orthodox sense of the word, *evil*. It is not and cannot be a contradiction of the true idea of human life, and at the same time a necessary element of it. Whatever necessarily belongs to life must help its true development, and not injure and destroy it; must be *good* in short, and not *evil*. Such theories, therefore, only solve the problem by eliminating the fact. The origin of evil must remain for ever inscrutable; nor is it wonderful that it should. It is only in its ultimate sense conceivable as a quality of moral freedom, and moral freedom in man or any created being is a profound mystery. It is something which 'we apprehend, but which we can neither comprehend nor communicate.'

The problem of the origin and existence of evil is dealt with by the most notable philosophers, as by Kant and

Hegel, but assumes special prominence in the pessimistic philosophers, Schopenhauer and Hartmann. According to Schopenhauer, not merely does pain greatly outbalance pleasure, but existence as such is necessarily evil (see *PESSIMISM*). John Stuart Mill, in his posthumous essays (1874), held that, in the presence of so much and so great evil, physical and moral, in the universe, it was impossible for him to believe in a deity at once omnipotent and all-benevolent. He felt therefore driven to regard God as a Demiourgos limited in power by the materials on which he had to work. See also *SIN*, *WILL*, and Julius Müller, *The Christian Doctrine of Sin* (trans. from the 5th German edition, 1868).

**Evil, KING'S.** See *SCROFULA*.

**Evil Eye**, the power of exerting an evil influence or fascination on any one by a glance from the eyes, one of the most venerable and widespread of human beliefs, sanctioned alike by the classical authors, the Fathers of the Church, the mediæval physicians, savage races everywhere, and modern usage in many countries within the range of Christianity. Readers of Virgil will remember the complaint of Menalcas in the third *Ecllogue* that some evil eye has bewitched his tender lambs, and every one is familiar with St Paul's bold metaphorical use of the idea to express the spiritual perversion of the Galatians (iii. 1). By the ancient Greeks it was called *Baskania*, by the Romans *Fascinum*; and to both it was an integral part of the popular belief. Amulets of very various forms—the most common those shaped like horns, like a frog, or like a hand—were worn to counteract its effect, and such devices adopted by way of safeguard as spitting on the ground or on the breast, showing something ridiculous to the fascinator, dissimulating good fortune, or doing something unpleasant by way of a counter-penance, like Polycrates of Samos throwing his ring into the sea. It was supposed that fascination was most often due to envy; hence the philosophy of overcoming it, and converting it into laughter and safety, by the exhibition of some ridiculous amulet, often of most indecent description. Such also were the *oscilla* or little masks of Bacchus hung upon fruit-trees to avert the *fascinum* and keep them fertile, and the *phallus* borne about in procession at the Dionysia. Of similar origin is the fact that stated numbers are particularly liable to the *fascinum*, and hence the deep-rooted Jewish disinclination to number flocks or the like, and the no less strong objection of Neapolitan and Scotch fishermen to state the number of their catch. In the folklore of almost every people it is considered unlucky to be praised with any particular warmth, and it is a point of prudence to use certain formulas immediately thereafter. We find this not only among the ancient Greeks, Romans, Celts, and Teutons, but among such people as the Turks, Italians, Spaniards, as well as the Chinese, Japanese, Negroes, and Red Indians. Thus, in Carniola and Corsica a mother does not care to hear her baby praised or a farmer his crops, while even in England here and there sick people still feel uneasy at being told that they are looking much better.

Nowhere at the present day has the belief in the evil eye a more real power than among the Neapolitans. The *Jettatura* is one of the common dangers incident to life, and every one wears his amulet against it. These are usually of silver, in the form of an antelope horn, a hand with the first and little finger doubled down, a key with a heart in its handle, a crescent moon with a face in it, or a sprig of rue. Other very common forms are the *cimaruta*, an emblem combined of all the foregoing, none of which are directly Christian symbols, and the *cavallo marino* ('sea-horser') and *sirena*, the last two being very common in Pompeian

paintings. The horror of this fatal gift of fascination with its blighting influence is deepened by the fact that it is exerted upon any object upon which the eye may first light, often, if not indeed usually, in opposition to the will of the person who is cursed with it. Men now possess it more commonly than women—nay, the *jettatore* is often a priest or monk, and it was long a matter of common belief that it was an unhappy attribute of Pio Nono himself. In ancient times, on the contrary, it was more common in women than men, and was possessed most often by little old women with squint or deep-set eyes, especially those who were lean and melancholy, and had double pupils. The Neapolitan *jettatore* is traditionally a morose and sallow man, eager to cast his blighting influence over men and women, but most commonly children, and usually he is a mean-looking personage, totally unlike the portentous figure idealised in the *Corricolo* of Dumas. Many of the medieval philosophers have seriously discussed the rationale of the evil eye, with its relations to the poisonous rays emitted by lizards and basilisks, and the fascination of terror exerted by the serpent upon the bird through keeping its eyes fixed steadfastly upon it. Grimm notes as one of the best means of recognising a witch, that when you look into her eyes you see your image reflected upside down, and suggests that the peculiar conformation may have had something to do with her evil eye. At any rate this baneful property is characteristic of witches everywhere, of none more than in those of Teutonic mythology.

See the learned discussion of the subject in W. W. Story's *Castle St Angelo and the Evil Eye* (1877); G. Pibré, *La Jettatura ed il Mal'occhio in Sicilia* (Kolozsvár, 1884); chap. vi. of E. N. Rolfe and H. Ingleby's *Naples in 1888* (1888); and M. Tuchmann's exhaustive series of papers on 'Fascination' in *Mélanges* (vols. ii. iii. and iv. 1884-80). For some valuable eastern evidence, see papers by John de Cunha and Purushottam Balakrishna Joshi in part iii. of the *Journal of the Anthropological Society of Bombay* (1888).

### Evil Merodach. See BABYLONIA.

**Evolute, Involute,** correlative terms first applied to the tracing of curves by Huygens. Under this distinction every mathematical curve is considered as one of a pair which are mutually produced. To measure the curvature at any point, or the amount of bending or deflection from the tangent, we find a circle which coincides with the curve for an elementary distance. This circle of curvature or 'osculating circle' must evidently diminish its radius as the curvature increases, and increase its radius as the curvature diminishes. The centre of this circle is called the centre of curvature for that point; and the successive points of any given curve have in general different centres of curvature, because the amount of deflection is constantly varying. When we trace, for example, an ellipse, the varying centre of curvature is at the same time tracing a companion curve of quite a different shape. The latter is called the evolute and the former the involute. Or we may begin with the evolute. Take a circular disc of metal or wood and wrap a thread round the circumference, which is now to serve as the generating curve. When the disc is held fast to any plane, and the string unwrapped under tension, any point of the latter will describe on the plane an involute of the circle. At any particular moment of the process the straightened or unwound part of the string is the radius of curvature of the outer curve. Thus, (1) the tangent to the evolute at any point is the normal to the involute at the corresponding point; (2) any curve as involute can have but one evolute, but any curve regarded as an evolute has an infinite number of involute

companion curves, which are all parallel; (3) the length of any arc in the evolute is the difference between the tangents at its extremities. When the circle is evolute, its involute (see fig.) is obviously spiral; and, when it is itself involute, the corresponding evolute has the exceptional form of being diminished to a point. The evolute of the cycloid is also exceptional, being another equal cycloid, a fact first observed by Huygens. A practical application of the involute of the circle occurs in theoretical mechanism in connection with the shape of the teeth of wheels, under certain circumstances.

From A, the beginning of the involute, draw a tangent AM = length of circumference of the circle.

Circle, BBB, as Evolute and its Spiral Involute, MNRSA.

Divide AM into eight equal parts (as figured) and the circumference into the same number at B, B, B, &c. At these points draw tangents so that line B1 = line A1, B2 = A2, B3 = A3, B4 = A4, &c. The extremities of the tangents show the curve called the involute of the circle. The dotted curves of the diagram show three of the companion involutes, all parallel to the first. They obviously admit of indefinite extension, however small the generating circle may be.

**Evolution.** Upon every developing mind, whether infantile or consciously philosophic, there presses at times the question of the origin of things. The attempt to answer this is to construct a cosmogony; and is alike the earliest and the latest extension of our common-sense account of things into complete and more orderly form as science. In seeking to do this the greater and more permanent phenomena at first impress us; and our speculative restlessness, if not lulled altogether, may seek to satisfy itself by postulating the existence of the universe substantially unchanged during an infinite past. But this philosophy of things is not only incapable of being really grasped by the highest effort of the intellect, but is incessantly contradicted by experience; it has hence never gained any real acceptance from the simplest common sense, much less any confirmation from science. The alternative then arises of drawing an explanation of the origin of things from our experience not of permanence, but of change. Here it is naturally the most changeable phenomena, the most marked and sudden contrasts, which first and most deeply arouse our attention, and this not only in nature, but still more in human life and affairs. The conception of uniformity among superficially different phenomena has hardly arisen, and the demand for explanations in terms of cause and effect, other than in terms of personal volition, is proportionately weak. The hypothesis of a sudden and unexplained, of a mysterious appearance or creation of things, thus next presents

itself; and the subsequent explanation of this as an act of external will is rendered easy by our personal consciousness. As our practical and industrial powers develop, and the perception of phenomenal order deepens and extends, the original simple association of a simultaneous appearance of all phenomena with a flash of volition is modified. Phenomena are becoming classified and interconnected in larger and larger groups, with which a higher anthropomorphism can henceforth associate a conception of detailed design. The older view only remains provisionally so far as order is not yet apparent; such later creationist theories become increasingly supplemented by a recognition of the changes in progress around us. The importance of these is found steadily to increase, and the conception of evolution, nascent since the crudest view of creation had given place to a more gradual and causal explanation, now becomes independently formulated in each order of phenomena. Human affairs become more and more obviously interpretable than of old, and there arises in their place the characteristically modern idea of progress. Natural science meanwhile has become more active, the very astronomical and geological phenomena from which our ideas of permanence were most derived are seen to be in process of change. Changes which seemed to be catastrophic in their vastness are proved to be only the cumulative product of natural agencies in daily operation; and the idea of the present as the product of the past also becomes extended to the world of organic life. The details, the general mechanism and direction of the processes of change, thus become inquiries of paramount interest to each body of scientific specialists and still more to the philosopher. It is at this period that we find ourselves, and to the brief discussion of these questions therefore that we must pass; but it is useful from the outset to recognise that instead of having well-defined and sharply-opposed theories of creation and evolution, these are but phases of an incomplete evolution. Hence the controversies so active during the middle half of the present century have practically ceased; it is admitted on all hands that the evolution theory only supersedes those cruder anthropomorphisms of arbitrary creation and of mechanical contrivance which presented the universe as a mere aggregate of finished products, without excluding that higher and more unified teleology which interprets it as the orderly unfolding of a cosmic drama. And as we see the evolution theory to be an orderly development beyond its predecessors, mere destructive criticism of these becomes no longer necessary.

*Mode of Treatment.*—The student of theology or philosophy, or the man of general education, is usually inclined at once to plunge amid the conflicting currents, the perplexing eddies of past cosmogonic speculations. He hence sets out by reviewing the oriental theories of the universe, and comparing these with Hellenic ones; he develops mingled types of both through early Christian thought into the elaborate compromise of the scholastic world; and finally endeavours to trace the modifications and survivals of these in contact with the thought-streams of the Renaissance and the Revolution before reaching the theories of modern times. But it would be a grave mistake to suppose that these last are the product of any continuous development from the preceding course of speculation. They have arisen independently and upon a distinct line, and present themselves as the most generalised result and expression of our concrete studies of natural science. Hence such historic inquiries, in all cases difficult, if not actually misleading, would be in any case premature; whereas, when we have grappled with the

scientific theories of evolution, we may then profitably note the analogies or parallelisms, the survivals of, or reversions to, earlier modes of thought which these present.

Scientific conceptions of evolution may themselves be approached from various sides. Minds of the more abstract type or training tend to begin with such a highly generalised analysis and exposition of the subject as that with which the labours of Herbert Spencer have been so pre-eminently concerned. After accepting or modifying this dynamic view of the universe as a whole, we should then seek to satisfy ourselves as to the applicability of our principles to the genesis of the physical world, and thence pass to the phenomena of life, mind, and society. We should then be accustomed to regard the universe no longer as a mere phantasmagoria, nor even merely as an orderly succession of events, but as a process of becoming. And, since this orderly flux of evolution is still in progress, scientific prevision thus becomes possible, and with it a corresponding degree of practical prevision as well. We thus reach a transition from the cosmist to the humanist attitude; the essential step from an evolutionary system of science towards an evolutionary system of ethics would then be made. These general conceptions reached, and an evolutionary philosophy in its broadest outlines being thus settled, we are in a position to review the earlier systems of different historic periods, and rationally criticise and interpret them in the light of our own conceptions; it may be even to recognise defects or deficiencies in these, and to obtain suggestions how to correct or supply them.

A less arduous and more popular method, concrete and inductive moreover, and consequently more in harmony with the modern spirit, is to begin as a scientific specialist, artificially isolating in thought one order of phenomena at a time from the complex unity of nature. Reviewing in this way the physical sciences, next the biological, and finally the mental and social, we shall be able to trace the parallel rise of evolutionary interpretations in each order of phenomena. And, after adequate detailed study of physical and organic processes, we may not only discuss the broader generalisations with fuller grasp and certitude, but proceed to inquire into the evolutionary process in higher sciences with ampler preparation; and thus ultimately approach the philosophic ideal of clearest and completest general view.

In this way we should have again completed the same cycle of thought as that sketched in the preceding section, but this time inductively instead of deductively: we have, as it were, worked our way upwards from our scientific primers instead of down from Mr Spencer's *First Principles* or the like. In short, then, the most simple, safe, and fruitful scientific method of studying the problem of evolution we find to be to reverse the order of the three distinct methods above outlined; to commence with the concrete study of evolution as manifested in the universe as a whole, in the earth's crust, and among plants and animals; gradually to rise toward more abstract expression and more deductive grasp, then to pass to mental and social evolution. Within the present compass the utmost that can be attempted is to sketch out a few of the leading lines of thought and still more briefly indicate others.

*Evolution in the Physical Sciences—Astronomy.*—Here, as in other sciences, early conceptions of the universe agree in viewing it as being, as far as possible, in permanence and at rest, and not in change and motion. Such static views may be only tacitly implied, but are more usually directly avowed: thus the earth was long viewed as a

plane stably supported, and till very recently the stars were viewed as fixed. But as the static universe of the ancient astronomer passes into that of Copernicus and Kepler, Galileo and Newton, Herschel and Leverrier, dynamic, or more accurately *kinetic*, conceptions have henceforward an assured prominence in at least one science, and that the one most obviously concerned with the universe as a whole. For although evolutionary speculations of more or less vagueness seem to have arisen once and again in almost every science, the first well-developed theory of evolution which has attempted to cope with the observed facts of any science must be credited to astronomy (if not to the professed astronomer) in the famous Nebular Hypothesis (q.v.), of which the suggestiveness to all other departments of science must be freely admitted. For the mind which has once fairly grasped the conception of stellar and planetary evolution cannot readily stop there.

*Evolution in Chemistry.*—In chemistry kinetic conceptions must naturally have been rife from the earliest times. The records of ancient chemistry are indeed largely those of the speculative exaggerations of kinetic hypotheses by the alchemists; as its history in more modern times bears the trace of a strong, and in some respects excessive reaction from these, albeit to occupy the more certain ground afforded by the conception of the permanence of matter. But the analytic researches, the studies of atoms and elements, of valencies and molecular constitutions viewed as absolutely definite, are again being used only as starting-points for new dynamic departures, such as those of thermo-chemistry; while new speculations, essentially evolutionist, such as those of Crookes and others, are arising on various hands around the well-known periodic law (see CHEMISTRY). The similarity in composition of our planet with that of sun and stars, and the intimate relation between organic and inorganic compounds, are also suggestive; while the actually observed genesis of many species of minerals by the action of natural causes, and the frequent transmutation of one species into another when some definite change takes place in the surrounding conditions, are not without evolutionary interest.

The recent movement in chemistry above alluded to is indeed only the counterpart of what has been taking place earlier and more fully in physics, thanks largely to astronomy and to the mechanical arts, not to speak of other influences. The laws of motion, the conception of gravitation, the abandonment of the theories of the material nature of light, heat, and electricity, are all steps of the same progress, as are also the positive demonstration of the existence of the imponderable ether, and finally the sublime conceptions of the conservation and dissipation of the evolution and dissolution of energy throughout the universe. And as the analytic task of the chemist and physicist rises from that of weighing and grasping at the atom to that of watching and measuring the wave, our general conceptions are inevitably changing also. The idea of a static universe, essentially constructed once for all of so many different masses and kinds of matter, upon which man of science, philosopher, and theologian alike formerly agreed, is on all hands fully giving place to that of a dynamic unity which owes its manifold and unceasing differentiation to the varying modes or moods of the universal energy.

*Evolution in Geology.*—That the last-century mineralogist was here and there already widening his interest to the rocks and even meditating as to their nature and origin is well evidenced by the penetrating speculation of Linnaeus: 'It may be that the solid rocks are not primeval, but the

daughters of time.' As subsequent generations of research have shown us, this solid rock is the product of igneous and that of aqueous action, here reaching back to an incalculable antiquity, or there evolved within the period of human occupancy; while others consist in great part, or even completely, of the remains of extinct animals or plants. These are conceptions now so familiar that it is difficult to realise their once revolutionary appearance and effect. But when we take into account the transition from the cataclysmal and essentially creationist theories which at first prevailed to the uniformitarian, or evolutionist, interpretation of geological phenomena which centres round the work of Lyell, we cannot wonder that such a revolution in geological doctrine should have exercised an influence upon general thought only second to that of the Copernican astronomy itself. More detailed studies, too, would be of no little service to our general theories; note, for instance, how the geologist takes from the astronomer, now a stellar evolutionist, the cooling planet, and outlines its primeval Sunderings of land and sea, its wrinkling hills and vales, how he proves that the pulse of ocean is but the dying ripple of a once fiftyfold mightier tidal wave, or how the glacial period is the inexorably recurrent winter of a year of ages. The mineralogist no longer merely measures and analyses, but deciphers the origin and transmutation of mineral species, and of the rocks they form under the forces of the environment (see MINERALOGY); and the typically changeeful phenomena of climate and atmosphere are rendered the subject of a typically dynamic sub-science (see METEOROLOGY).

*Modul Explanation of Physical Evolution.*—We must sooner or later inquire whether any general principle can be found to verify and rationalise the process of evolution in the physical world, and to this the answer has been specially elaborated by Mr Herbert Spencer. His essential principle or Law of Evolution must be stated in his own words: 'Evolution is an integration of matter and concomitant dissipation of motion during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity, and during which the retained motion undergoes a parallel transformation.' The deductive and inductive establishment of this principle, and its comprehensive verification and fruitful application throughout the fields of the higher sciences as well, are necessarily left for fuller separate exposition (see SPENCER). And although the student who seeks to follow Mr Spencer in grappling with the riddle of evolution in higher orders of phenomena may not admit that his uncompromising application of the principles of physical evolution to higher categories is so exhaustive and satisfactory as he claims, there can be no doubt that this general treatment has been on the whole amply justified so far as it goes, alike in unifying the sciences, and in the separate organisation of these.

*Evolution in Biology.*—This portion of the subject demands special attention and fullest outline for many reasons. Not only is the transition from static to evolutionary conceptions of comparatively recent, indeed almost contemporary interest; but the progress of the doctrine of evolution as a general theory of the universe has been most closely connected with progress in biology. And while we can at best merely speculate as to the direct continuity of evolution from the inorganic to the organic world (see BIOLOGY, SPONTANEOUS GENERATION), we are constantly impressed by the fundamental unity of the process in the simplest and most complex forms of life, and by the thoroughness with which the same principles may be traced into the highest 'euperorganic' phenomena of mind and society.

At the outset we require some such conception of

the actual historic progress of our concrete knowledge of plants and animals as is outlined in the articles BOTANY and ZOOLOGY, and also of that rise of our more abstract kinetic and static (physiological and morphological) interpretations of the phenomena of life as is given under BIOLOGY and BOTANY. The general argument for evolution appended by Darwin to the classic statement of his theory of Natural Selection in the *Origin of Species* has been already summarised under DARWINIAN THEORY, and its separate heads are also to be found under separate articles; only the briefest reference to these need here be made. We must keep, for instance, in view the conceptions of the actual evolution of the individual which have become systematised in the sub-science of embryology (see EMBRYOLOGY). Suffice it, however, here to recall that, although it is in this connection that the term *evolution* first makes its appearance, it is used along with *development*, in a sense diametrically opposed to its present significance, as the mere enlargement and unfolding (*evolutio*, *evolution*, *Entwickelung*) of a form and structure in all essential respects a perfect miniature of that of the adult.

Without recording or analysing the various conceptions of species (see SPECIES) it is sufficient again to note how the belief in their objective constancy and practical definableness is shaken by such facts as (1) that pre-evolutionary systematists differ hopelessly upon the number and limits of the species of all the more variable groups of plants and animals; (2) that the mere numerical increase of the number of specimens in our museums is constantly compelling us to recognise that great numbers, sometimes even scores or hundreds, of 'type-specimens' of irreproachably described 'species' are but so many individual members of a series linked by the most infinitesimal gradations, yet of which the extremes differ by characters of specific, it may be even generic rank. And when (3) the assumption of the general sterility of hybrids is proved experimentally (see HYBRID) to be an exaggeration, it becomes, to say the least, increasingly difficult seriously to support the dogma of the constancy of species.

Leaving the general external form with which the species-maker is mainly concerned, we must accompany the anatomist through each level of his deepening analyses and comparisons, through organ-systems and organs, tissues and cells, to the ultimate protoplasm itself (see BIOLOGY, MORPHOLOGY). To realise how fully this analysis results in the demonstration of an unsuspected unity of structure not only between species and genera, but far larger groups, some actual study of the concrete facts is indispensable; as also to appreciate the same beautiful unity of type in individual structures so differentiated as the appendages of a lobster (see CRUSTACEA) or the parts of a flower (see FLOWER). Yet here again we have an instance of the tenacity of static conceptions; for although it could not be actually denied that the hypothesis of descent from common ancestors at least *might* explain the structural unity observable under classification, as from a simpler ancestor, that observable under the individual structure, the conception of conformity to a purely ideal 'archetype,' was long maintained. Rudimentary organs, such as the teeth of foetal whales, were thus explained not as reduced survivals of structures ancestrally useful, but as purely intellectual necessities of this arbitrary 'conformity to type.' This ingenious revival of Platonic ideas in conjunction with scholastic nominalism could not, however, very long survive the demonstration of the frequent absence of rudiments necessary for archetypal purposes; and the alternative evolution-

ary explanation has thus inevitably succeeded to its place.

It is much to learn from the taxonomist that his classification of species and genera, even the whole world of plants or animals, assumes the form of a vast genealogical tree; and it is no small confirmation of the evolutionary view to note how every new fossil-trove throws some fresh light upon the order in which the branches or branchlets of this tree have historically developed. With all the missing links we can imagine or desire between the modern horse and his simple five-toed ancestor (see PALÆONTOLOGY, FOOT, HORSE), not to speak of other examples, we have indeed evidence which may well satisfy us of the historic fact of evolution; but this brings us no nearer comprehending the rationale of the process. Leaving the morphological sciences, we must pass with Darwin to the study of what we may call the higher physiology. Assuming what is known of the functions of the individual, we must note not only the relations of the species unit (in higher forms usually of course the pair), and so familiarise ourselves with the phenomena of reproduction and sex, of heredity and variation, breeding and relation to offspring, the results of intercrossing, the modification by environment, &c.; we must also consider the wider relations among the members of the same species, between allied species, and finally between practically unrelated ones, whether here of struggle or there of adaptation. He thus introduces us to this vast and practically new field, and gives us a glimpse of the living, whole nature in that magistral series of volumes, which we may as it were group into a *Vita Naturæ*, complementary to the static *Systema Naturæ*, and no less epoch-making for our day than was that of Linnaeus for his.

We see how natural it is that the student of biology who thus becomes an evolutionist so largely by help of Darwin, should accept the lucid and comprehensive modal explanation so vitally associated with his whole evolutionary attitude, and thus also become a thoroughly convinced Darwinian, a natural selectionist without more ado; and we can readily understand that the assent of the majority of the intelligent public should have gradually followed the same course during the generation after the publication of the *Origin of Species*.

It is necessary, however, to refer more precisely to the history of opinion both as regards the fact of evolution and the factors in the process. The history of the two questions—of the empirical fact, and of the actual mechanism of evolution—can hardly be separated, though it is of course well known that the former was virtually settled by the demonstrations of Spencer, Darwin, Wallace, Haeckel, and others soon after the middle of this century, while we are still in the midst of keen debate as to the relative importance of the diverse factors. The history of the theory of evolution, so far as the organic world is concerned, is essentially modern, for in spite of vague hints and *a priori* speculations from Empedocles onwards, it was not till the 18th century that evolution began to be very definitely suggested as a modal explanation of the origin of our fauna and flora, or that inquiry began to be seriously directed to what we now call the etiology of organisms.

What was for so long only a germ-idea at length took shape in the mind of Buffon (1749), who not only urged the general conception with diplomatic skill and covert irony, but sought to show how new conditions evoked new functions, how these in turn reacted upon the structure of the organism, and how, most directly of all, altered climate, food, and other elements of the environment might be

the external conditions of internal change, whether for progress or the reverse. Erasmus Darwin (1791), with a truly living conception of nature, emphasised the organism's inherent power of self-improvement, the moulding influence of new needs, desires, and exertions, and the indirect action of the environment in evoking these. To Treviranus (1802-31) organisms appeared almost indefinitely plastic, especially, however, under the direct influence of external forces, nor did his analysis of possible factors fail to recognise what Brooks, Weismann, and others have recently elaborated, that the union of diverse sexual elements in fertilisation was in itself a fountain of change. His contemporary Lamarck (1801-9) is well known to have emphasised the importance of changed conditions in evoking new needs, desires, and activities, while urging also the perfection wrought by practice and the degeneration which follows as the nemesis of disuse. Evolution seemed to him the interaction of two fates—an internal progressive power of life, and the external force of circumstances in the twofold struggle with the environment and with competitors. Among the philosophers also, especially in the minds of those who had been disciplined in physical or historical investigations, the speculations of the ancients were ever taking fresh form, gaining moreover in concreteness; witness the contributions of Kant and Herder. In Goethe's epic of evolution the adaptive influence of the environment is clearly recognised, while the misty theories of his contemporary Oken chiefly interpret the organic progress in terms of action and reaction between the organism and its surroundings. Wells in 1813 and Patrick Matthew in 1831 forestalled Darwin in suggesting the importance of natural selection, but their buried doctrines were of much less practical importance than those of Robert Chambers, the long unknown author of the *Vestiges of Creation* (1844-53). His hypothesis of evolution emphasised the growing or evolving powers of the organisms themselves, which developed in rhythmic impulses through ascending grades of organisation, modified at the same time by external circumstances acting with most effect on the generative system. In France, Geoffroy and Isidore St Hilaire, father and son, supported the thesis of definite variation under direct environmental influence. And before reaching even the contemporaries of Darwin a complete history would have to take account of the conclusions of many naturalists, such as Von Buch, Von Baer, Schleiden, Naudin, and Wagner. The environmental factor was subsequently recognised with greater clearness and with less exclusiveness by Spencer; while Darwin and Wallace, recognising some truth in most of the above positions, but believing them wholly insufficient, left the problem of the origin of variations alone, and devoted their strength to establishing the theory of the origin of species by means of natural selection, a view which emphasises the destructive or eliminating and the conservative or selective action of the animate and inanimate environment in the struggle for existence.

Even from the above brief sketch of representative conclusions, it will be seen that successive authors accent diverse factors in the evolutionary process: in the view of one the organism has a motor power of variation inherent in its very constitution, or gained by the intermingling of sex-elements from which the individual life starts; to another the moulding power of changed function, the perfecting influence of exercise, the degenerating nemesis of disuse are all important; while to a third organisms seem to have been hammered from one shape into another by the action of that complex series of external influences which we briefly term the environment. Among modern

naturalists we find champions of each of these three positions respectively emphasising (a) the organism itself, (b) its function, and (c) its environment; a few remain more or less exclusive Natural Selectionists, with or without theories of the origin of the variations which they postulate; while the majority more and more incline to an eclectic but not yet synthetic view, differing chiefly in regard to the relative importance of the various factors recognised.

The difficulty will be obvious of even briefly discussing so many positions, many of which are better dealt with under the separate articles ENVIRONMENT, HEREDITY, REPRODUCTION, SEX, VARIATION; and it is undesirable here to stereotype any one position as final during an unended controversy. That criticism will be certainly more temperate, and probably not less fruitful, which for a time seems to withdraw from the actual field of battle; which, instead of joining issue on this point or upon that, seeks rather to recognise all the leading points of view from which the subject may be approached, and thence to clear up the various lines on which a modal explanation is or may be offered, or to which it must at anyrate be capable of satisfactory application. We should thus even be able to do more justice to the older naturalists' positions.

*Evolution in Psychology.*—The psychologist admits the same inability to derive psychical processes and states from the nutritive and reproductive functions and structures which form the subject-matter of biology that the biologist does to derive these from inorganic processes. This fact does not of course interfere with the investigation of the parallelism of each of these higher orders of phenomena (see BIOLOGY), still less with the detailed study of evolution in mind, for which, as Mr Spencer has especially demonstrated, evolution in the preliminary sciences of biology and physics is so suggestive. What most concerns us here is to note how largely the science of psychology, or what stood for it, was wont to be a matter of deduction from that time-honoured axiom that human nature is for practical purposes always and everywhere the same; which, as evolutionists, we now see to have been an erroneous postulate. The older psychology was concerned especially with less or more scientific analyses of the adult mind, and this usually of the isolated 'typical' one (usually of the psychologist himself), but in a form too generalised to admit of much practical application. The modern school recognises the necessity of unravelling the vast complexity of the actual details of psychical processes, and not only eagerly investigates the development of the infantile mind, but scrutinises the kindred though humbler phenomena of animal cerebration. Psychology is drawing new light from the long discredited study of hypnotic states (see ANIMAL MAGNETISM); since here psychical functions can be analysed at various levels, and this apart from the perturbing action of the will. Again, it finds a rich source of knowledge in those morbid variations towards excessive or deficient cerebration and neurulation which we group under the complex term Insanity (q.v.). Yet that it reaches also the most complex concrete products of evolution is evidenced by the rise and progress of criticism in literature and art. That we have here the closest parallelism to biology and its progress is manifest, as our current phrases of comparative psychology, of mental physiology, pathology, variation, and the like clearly show. We see, indeed, that the science of psychology is now more biological, more evolutionary, and more unified than biology itself, which is still so largely limited by the numerous and confused dispersive and analytic specialisms from which it has arisen, and which it

is still so far from having reorganised. The transition from the static to the kinetic attitude is thus more nearly complete. The debt of science to practice is here obvious in the gain from education and mental hygiene; while the return of the science into practice, as yet only incipient, promises results of the vastest kind. Education would at length have to be viewed and practised in an evolutionary sense, as the process of assisting the entire development of the individual into, it may be beyond, the actual living powers, into the stature and beauty, of the race; instead of smothering the development under the mere accumulation of its dead results in certain fields of detail. Nor is the parallelism of psychical and physiological processes, which enables us to modify more and more mind through body, failing to open up subtler possibilities of modifying body through mind.

*Evolution in the Social Sciences.*—Leaving fuller treatment to the article SOCIOLOGY, and such special articles (POLITICAL ECONOMY, &c.) as are therewith connected, we may note that the social sciences of the pre-evolutionary period, although represented on its concrete side by history, and its abstract side especially by political economy, was essentially static. History was necessarily a record of occurrences at specified dates, which, although sometimes set forth in their minor relations of cause and effect, did not admit of any large co-ordination in scientific terms; though the continual attempt by theologians and metaphysicians to construct a philosophy of history indicated at least the need of this. Upon the abstract side we have those attempts to formulate a purely deductive 'science of political economy,' which still so largely survives; although its pretended laws, deduced from postulates of the archaic psychology, such as that of action exclusively arising from self-interest, or from metaphysical abstractions such as utility, are now being replaced by generalisations drawn from the inductive study of social phenomena, actual and historic, and by principles firmly established in the preliminary sciences. The derivation of our whole body of social knowledge from social practice is here of course absolute, all the phenomena being human ones; and the reaction of theory upon practice can only at first sight seem disproportionately small when we lose sight of the importance of the past thought systematised in legal and religious systems. In the world of material interests static views have as yet essentially prevailed: witness the incomparable antiquity of law as compared with that of the modern process of law-making and unmaking which we call internal politics—a form of activity which, however disappointing in its practical results, has at least had something to do with the even more recent emergence and popularisation of the idea of social progress. This characteristically modern idea became increasingly systematised, on the one hand through special studies, and on the other through the unparalleled progress of the mechanical arts. We must note also that the very recent foundation of sociology as a distinct and unified science depended upon the attainment of a synthetic interpretation of the history of western Europe both material and intellectual as the central process of the general evolution of humanity; while no subsequent labours on behalf of the nascent science have been greater than those of that later thinker who has been far more concerned than any other with the general philosophy of evolution.

That the idea of evolution has originally been projected from the social plane into that of the other sciences, is a proposition which can only be doubted by the specialist who has not inquired

into the history of his ideas; evolution in social affairs has not only suggested our ideas of evolution in the other sciences, but has deeply coloured them in accordance with the particular phase of social evolution current at the time. The hermit not unnaturally supposes his cosmist meditations to be wholly unspotted by the world he has left behind, but this cannot prevent the historian from rigorously viewing his whole thought and conduct as a product of that world. Nor is absolute demonstration difficult even from the strictest biological specialist's own postulate—that life is interpretable merely as a biological phenomenon. Be it so: then science is the summed (phylogenetic) experience of the race, and the investigator's contribution to it is of course measured by his own development (ontogeny). But the development of an organism, functional and cerebral, is so far *pari passu* with its adaptation to the world around it, but still more in relation to its own species. In other words, the measure of individuation attained by the individual of any species as compared with its fellows is dependent in the first place upon sexual maturity, (2) upon the relations to offspring towards which this tends to develop, and (3) upon the measure of sociality which in so many species arises through the widening of this direct reproductive relation into that of a larger aggregate. This is a proposition which the biologist should be the last to dispute; hence, while arguing for the evolution of the human species by the same agencies which have shaped the lower ones, it is impracticable permanently to retain the absurd assumption, inherited from pre-evolutionary psychology, that mental development goes on as it were in *vacuo*, without reference to the expansion of the organic functions of self-maintaining and species-maintaining. But as this survival becomes outgrown the pure biologist will of course be the first to emphasise and elaborate the proposition that all human developments, like those of any other species, are in terms of these.

*Modal Explanation of Organic Evolution.*—The conception thus reached of the measure of evolution of a species being expressible in terms of the progress of its (1) self-maintaining and (2) species-maintaining functions is equally capable of statement in biological, psychological, sociological, or indeed also, as moralists are now agreeing (see ETHICS), in ethical terms; what are termed egoistic or altruistic actions being respectively self-maintaining or species-maintaining ones, of course at different levels of evolution. Here, then, we have a basis for the required inquiry as to the mechanism of the evolutionary processes. The evolutionist at any rate will not dispute this parallelism between the non-ethical aspects of organic evolution, nor deny that the results and processes of evolution in their highest manifestations may be of service in elucidating or criticising the similar ones which must be supposed to exist in less developed forms. Hence he would be in some respects even better justified in tracing the evolutionary process down from the highest aspects to the more simple ones, and from the human species to humbler ones, than conversely: thus the limitations of the doctrine of natural selection may be better understood, and this on two or three distinct sides. It is not altogether easy to meet the criticism sometimes urged by the economist that the process which kills off the weakest of the race weakens and deteriorates those which survive, and that, while some struggle for existence is needful for individuation, human progress is yet observably associated with an advance of the subsistence fund over the requirements of maintenance. Without

insisting upon the difficulties urged by Wallace, Mivart, and other evolutionists as to the descent of man (see MAN, DESCENT OF), the ethical difficulty so common to all inquiries respecting evolution and natural selection in general, but human evolution in particular, cannot be escaped. For we have as yet little beyond the cheerful optimism which sets off the cumulative gain to the species against the incessant sacrifice of the weak to the strong which is in constant progress alike in nature and in human society. And if this be indeed the spring of human progress, how can we resist the logic which calls upon us to remove those adjustments for the mitigation of the struggle for existence for the protection of the weaker, with which, however, not only our feelings and what we have been accustomed to call our higher instincts, but our whole civilisation, material and moral, are inextricably bound up? A classical statement of the central difficulty, of which the Darwinism and the morals are alike unexceptionable, and the resultant dualism therefore clearly set forth, may be quoted from Huxley: 'From the point of view of the naturalist the world is on about the same level as a gladiator's show. . . . We must say that its governing principle is intellectual, and not moral, that it is a materialised logical process accompanied by pleasures and pains. . . . Society differs from nature in having a definite moral object. . . . The ethical man tries to escape from his place in the animal world founded on the free development of the principle of non-moral evolution, and to found a Kingdom of Man, governed upon the principle of moral evolution. For society not only has a moral end, but, in its perfection, social life is embodied morality. But the effort of the ethical man to work to a moral end, by no means abolished, perhaps has hardly modified the deep-seated organic impulses which impel the natural man to follow his non-moral course.'

The natural selectionist sometimes seeks (as Mr Darwin has indeed himself done) to escape this frank return to a pre-evolutionary ethical dualism by reminding us that, since on his view 'nature trusts to the chapter of accidents for variation,' favourable ethical variations may spontaneously have arisen at the social plane. But even if the dawn of similar variations in lower species did not raise a probability of the definite rather than fortuitous nature of such variations, the unity of all the four aspects of organic evolution is none the less given up.

The theory of natural selection is now, however, itself undergoing an evolution which promises fair for an escape from these difficulties, and this on all hands. In its classic form it assumed selection to operate upon an indefinite number of individual variations, which Darwin, at least in some moods, was quite ready to admit might be produced by environment, increased by function, and the like; but which, once selected, were preserved by heredity and frequently increased by new spontaneous variations in the same direction. Now, however (see HEREDITY), we have an ultra-Darwinian school founded by Weismann, and followed by Lankester and many others, which, denying the heredity of acquired characters, pushes back the origin of all variations of species-making importance into the protoplasm of the sex-elements, and so seems to leave natural selection as the only factor of evolution which we can really hope intelligently to grasp, variation seeming inscrutable. The neo-Lamarckian school, on the other hand, with which Spencer must also be reckoned, holds a very different doctrine, that of the importance of individual function and the transmission of its modifications; while the influence of environment is also coming

to be studied with not only speculative acuteness but experimental detail. Variation is again being more and more frequently regarded as taking place on a few definite lines; and the origin of species is viewed as a liberal development of internal conditions in the species as in the development of the individual, which environment can only bend and colour, and natural selection no more than prune. Such views (see VARIATION), too often formulated with excessive generality and indeed vagueness, yet on the whole with increasing concrete application to detail, are maintained by Nägeli, Cope, Eimer, and many others, including the present writer. It will at any rate be recognised that there is ample room for such inquiries, and that the importance claimed by natural selection cannot be safely established until they have been disposed of in favour of that hypothesis of indefinite variability upon which this importance essentially depends. It is becoming more and more apparent that it is the problem of variation which is fundamental to selection.

Amid so many various opinions Mr Wallace has come to stand almost alone as an avowed exponent of the theory of natural selection in its classic form; yet even he not only makes the reserve as to human descent above alluded to, but seeks to replace Mr Darwin's sexual selection (see SEX) by a new hypothesis, and so enlists the services of that heresy of definite variation which is so irreconcilable with Mr Darwin's general argument.

The general drift of the contemporary discussion is thus beginning to be apparent: all theories and criticisms have hitherto started with the individual as the unit, and the origin and differentiation of the self-maintaining structures and functions as the primary problem; after which the origin and differentiation of reproductive and species regarding processes have been left only a secondary and subsequent place. But we are beginning to discover that this method of approach, however natural to the individual thinker, is artificial as respects nature; we have above been noting how many different lines of research are turning from the self-maintaining to the species-maintaining process; and the centre of gravity of the science is in fact undergoing a revolutionary change. In thinking of a species we have been wont to call up and investigate the individual type, and to recognise the process of reproduction subsequently only as giving us a less or more varied repetition of this type; but this is a survival of the static and anatomical view. What the general physiologist is now coming to recognise in the species, and what accordingly the evolutionist *a fortiori* must keep in view, is primarily its living continuity, no longer the details of its separate links. From this most general point of view both are coming to see the most complex individual lives, in Foster's phrase, as but the 'by-play of ovum-bearing organisms.' The species is a continuous undying chain of unicellular reproductive units which indeed build out of and around themselves transient multicellular bodies; but the processes of nutritive differentiation and other individual development of these is the secondary, not the primary question.

Instead, therefore, of beginning with the origin and adaptation of the details of self-maintaining advantage, coming later to those of reproduction and sex, and only recognising the mysterious control of the principle of correlation of organs in the background of the whole process, as Darwin and other evolutionists have been wont to do, a fuller initial recognition of the reproductive process raises the question of correlation between the reproductive and individual functions at the outset. We see the sexual development of animal, and still more obviously of plant, everywhere becoming a most

potent determinant of its adult character, and one of classificatory importance far deeper than the mere individual characteristics of the separate species. We see again how the nature and degree of relation to offspring gives a new key to the larger aspects of classification. Thus it is the central generalisation of botany that despite the individual differentiation of fern, selaginella, cycad, conifer, and flower, these turn out on deepest analysis to be but the surviving phases of a continuous and definite increase in the subordination of the sexual parents to their asexual offspring (see FLOWER). Or in the same way, while we define the orders and sub-orders, genera and species of the mammalia by help of the individual apparatus for maintenance or struggle, the larger question of the characteristics of the mammalia, and of their main subdivisions, does not depend upon any mere accumulation of these, as Darwin's very natural application of Lyell's well-known argument would require: for not only the mammal but its essential types, monotremes, marsupial and placental, and even again the subdivisions of the latter, express so many stages in the progress of maternal sacrifice for offspring. In the same way with the evolution of sociality which arises from reproductive aggregation in so many species, we see this subordinating struggle, greatly facilitating not only the increase in numbers of the species, but their higher specialisation as well. We escape from the conception that progress depends primarily upon internecine struggle for existence—i.e. the subordination of the species to the individual, instead of primarily upon that of the individual to the maintenance of the species in sex, offspring, and society. Thus our ethical difficulty at length disappears, since the greater steps of advance in the organic world compel us to interpret the general scheme of evolution as primarily a materialised ethical process underlying all appearance of 'a gladiator's show'.

The corresponding progress in the historic and individual world from sex and family up to tribe or city, nation and race, and ultimately to the conception of humanity itself, also becomes increasingly apparent. Competition and survival of the fittest are never wholly eliminated, but reappear on each new plane to work out the predominance of the higher, the more integrated and associated type; the phalanx being victorious till in turn it meets the legion. But this service no longer compels us to regard these agencies as the essential mechanism of progress, to the practical exclusion of the associative factor upon which the victory depends, as economist and biologist have too long misled each other into doing. For we see that it is possible to interpret the ideals of ethical progress—through love and sociality, co-operation and sacrifice, not as mere utopias contradicted by experience, but as the highest expressions of the central evolutionary process of the natural world. To continue the generalisation of the process of evolution, organic and super-organic, which Mr Spencer, himself repeating on a higher spiral the thought-cycle of many an earlier thinker, has so fully reopened, is to raise anew all the problems of philosophy, which are indeed in a state of evolutionary flux. The singers too of evolution are gathering fuller voice; we have not only indeed fully entered upon evolutionary reorganisation of thought but the corresponding leavening of all forms of art and even of practical life.

See books cited at DARWINIAN THEORY; also articles on the subjects above mentioned, particularly VARIATION, and those on special authors, as SPENCER, LAMARCK, &c. The converse ascending treatment of Evolution, from protoplasm onwards, as in Spencer's *Principles of Biology*, is outlined under EMBRYOLOGY, CELL, PROTOPLASM, and VARIATION.

**Evolution**, in Algebra. See INVOLUTION.

**Evora** (ancient *Ebora*), one of the most interesting cities of Portugal, capital of the province of Beira, is charmingly situated on a hill.

hopelessly ruinous condition, and to some extent by modern fortifications as yet unfinished. It is a very ancient city; Quintus Sertorius took it in 80 B.C., and it was also conquered by the Moors in 715, but recovered from them in 1139. Among the famous Roman antiquities of Evora are the temple of Diana, with fine Corinthian columns; an aqueduct erected by Quintus Sertorius, and restored in the 16th century, which still supplies the city with water; and the beautiful tower, surrounded by Ionic columns, which rises in the city at the extremity of the aqueduct, and which, although it has existed since 70 B.C., is in almost perfect preservation. The town itself is not well built, and the streets are narrow, winding, and dirty. It has a cathedral, founded in 1186, and afterwards restored in the Gothic style. It has been the see of an archbishop since 1540, and has an archiepiscopal library, containing, besides some 25,000 volumes, several pictures of great merit. There are some manufactures of cotton, cloth, and hats, and a trade in wine. Pop. 13,046.

**Evremond**, CHARLES MARGOTELLO. See SAINT-EVREMOND.

**Evreux** (ancient *Mediolanum*, later *Ebuovices*), the capital of the French department of Eure, is situated in the fertile valley of the Iton, a feeder of the Eure, 67 miles by rail WNW. of Paris. The cathedral, of various dates from the 11th to the 18th century, is a cruciform structure, with Italian facade, a central spire, and fine painted glass. Other buildings are St Taurin's, with a 13th-century shrine, which once contained the relics of that saint, the first Bishop of Evreux; the episcopal palace (1484); and the 'Tour de l'Horloge,' of the same century. Evreux has extensive manufactures of paper, linen, &c., and a trade in grain, seeds, timber, and liqueurs. Pop. (1872) 10,702; (1886) 13,135. Evreux has sustained innumerable sieges, having been sacked in 892 by the Northmen under Rollo, burned by Henry I. of England in 1119, and in 1194 and 1199 captured by Philip Augustus of France. It was frequently taken and recovered in the wars between France and England during the reigns of our Henry V. and VI.—At the neighbouring village of VILLIÈVREUX, supposed to mark the site of *Mediolanum*, excavations have disclosed remains of a theatre, an aqueduct, baths, &c.

**Ewald**, GEORG HEINRICH AUGUST VON, the famous Orientalist, was born 16th November 1803, at Göttingen, where his father was a cloth-weaver. From 1820 he studied at the university, under Eichhorn, theology and philology, devoting himself especially to the oriental languages; in 1823-24 he was a teacher at the gymnasium at Wolfenbüttel; in the latter year he published his first work, *Die Komposition der Genesis*, and was appointed a theological tutor in his own university of Göttingen. After this he became in 1827 an extraordinary professor, and in 1831 ordinary professor of Philosophy, and in 1835 nominal professor of Oriental Languages. For his share in the protest of the seven Göttingen professors against the annulling of the Hanoverian constitutional law he was deprived of his chair by a rescript of the 12th December 1837; and after spending some months in England he was called to a chair at Tübingen, where he remained for ten years and a half. He was ennobled by the king of Württemberg in 1841, and in 1848 was recalled to Göttingen, where he spent the remainder of his life. In consequence of his refusal to take the oath of allegiance to the

Prussian government, he was at his own request pensioned off in 1867. His earlier works, chiefly devoted to the grammar and metres of the oriental languages, include *De Metris Carminum Arabicorum* (1825), *Versuch über einige ältere Sanskritmetra* (1827), *Grammatica Critica Lingue Arabicæ* (2 vols. 1831-33), and his *Kritische Grammatik der hebräischen Sprache* (1827), which he reproduced in an abbreviated form in his *Grammatik der hebräischen Sprache* (1835, 3d ed. 1838), and with greater fullness of detail in his *Ausführliches Lehrbuch der hebräischen Sprache* (8th ed. Gott. 1870). The scientific results of his travels are partly contained in his *Abhandlungen zur orientalischen und biblischen Literatur* (1832), and in his *Zeitschrift für die Kunde des Morgenlandes*. The rich fruit of his lifelong study of the Old Testament is stored in *Die Dichter des Alten Bundes* (2d ed. 3 vols. 1866-67; Eng. trans. of Psalms, 2 vols. 1880-81, of Job, 1882), *Die Propheten des Alten Bundes* (2d ed. 3 vols. 1867-68; Eng. trans. 5 vols. 1875-81), *Beiträge zur Geschichte der ältesten Auslegung und Spracherklärung des Alten Testaments* (3 vols. 1844), and finally in his magnificent masterpiece, *Geschichte des Volkes Israel* (3d ed. 7 vols. 1864-68; Eng. trans. in 8 vols. 1867-86), with the supplement, *Die Alterthümer des israelitischen Volkes* (3d ed. 1866; Eng. trans. 1876). To the study of the New Testament Ewald contributed his *Jahrbuch der biblischen Wissenschaft* (12 parts, 1849-63), *Die drei ersten Evangelien* (1850), *Die Sendschreiben des Apostels Paulus* (1857), *Die Johanneischen Schriften* (2 vols. 1862), *Uebersetzung und Erklärung aller Bücher des Neuen Testaments* (7 vols. 1870-72). Of his other works the most noteworthy are his *Erklärung der grossen phönizischen Inschrift in Sidon* (1856), *Ueber die phönizischen Ansichten von der Welterschöpfung* (1857), *Die Silyllinischen Bücher* (1858), *Das vierte Ezra-buch* (1863), *Sprachwissenschaftliche Abhandlungen* (1861-71), *Abhandlung zur Zerstreuung der Vorurtheile über das alte und neue Morgenland* (1872), *Die Lehre der Bibel von Gott* (3 vols. 1871-75). In his scientific studies, Ewald followed his own way. His hand was against every man, and he was impatient of contradiction. He was an equally vigorous adversary of the 'Tübingen School' and of the orthodoxy of Hengstenberg and Delitzsch. In the prefaces and postscripts of his books, and in his year-books for biblical science, he frequently took occasion to express his uncompromising views on the political and ecclesiastical questions of the day, and frequently shows an entirely unjustifiable severity in criticising those from whom he differed. From 1869 he represented Hanover in the Reichstag, and was a decided opponent of the ambition of Prussia. He died of an affection of the heart, 4th May 1875. An autobiography, which he wrote in the last months of his life, was still unprinted in 1889. A monument was erected by his disciples over his grave at Göttingen. Ewald brought to the interpretation of the Hebrew prophets a spirit akin to their own—Hase describes him as a prophet with backward gaze. His patriotism and courage, his poetic fire and energy, his spiritual insight and marvellous power of sympathetically reproducing primitive experiences by the divinations of genius, and the indefatigable industry with which he applied his perspicacity and insight to understand the Hebrew nation and its sacred literature have secured for him the highest place among the biblical scholars of his century. See two admirable critical papers on the life and work of Ewald by Professor Cheyne, in the *Expositor*, third series, vol. iv. (1886).

**Ewald, JOHANNES**, a Danish poet, was born 18th November 1743, at Copenhagen, where his father was a pastor of the strictest pietistic views.

Before his father's death he went to a school at Sleswick, from which he ran away to seek an uninhabited island like that of Robinson Crusoe, but did not get farther than Hamburg. In 1758 he began to study theology at Copenhagen. His love of adventure led him to Magdeburg, where he entered an infantry regiment. He soon deserted to the Austrian army, in which he was first a drummer, then an under-officer. After taking part in several engagements in 1759-60, he obtained his discharge, and returned to theological study at Copenhagen. A disappointment in love was the turning-point of his life. After this he gave his attention solely to poetry. To this also he attributed the irregularities of his life, which bore bitter fruit in the poverty and ill-health of his later years. The allegorical poem, *Lykkens Tempel*, published in 1764, was well received; but it was not till two years later, in his elegy on the death of Frederick V., that he gave clear proof of his lyrical power. The biblical drama, *Adam og Eva* (1769), shows clear traces of the influence of Klopstock. His other writings include a series of satiric plays; the prose tragedy, *Rolf Krage* (1770); and the two masterpieces, *Balters Dod* and *Fiskerne*, the latter containing 'Kong Christian stod ved højen Mast,' which has become the national song of Denmark. He died on the 17th March 1781, leaving an incomplete autobiography, *Johannes Ewalds Levnet og Meninger*. Though he was scarcely thirty-eight years old at his death, Ewald's work has taken a pre-eminent part in the development of Danish literature. Oehlenschläger has testified in some of his finest poems that Ewald was the creator of the modern poetry of Denmark. As Holberg was the father of Danish comedy, so Ewald was the founder of Danish tragedy. Yet his noblest productions are his lyrical poems and odes, the pure beauty of which is scarcely to be surpassed. The best edition of his works is that of Liebenberg (8 vols. Copenhagen, 1850-55). See the *Life* by Hammerich (1860).

**Ewell, RICHARD STODDERT**, Confederate soldier, was born in Georgetown, D.C., in 1817, served in Mexico and against the Apaches, and was actively engaged throughout the civil war. In 1862 he fought with distinction under Jackson, losing a leg near Bull Run in August; and, having been promoted lieutenant-general, he served gallantly at Winchester, Gettysburg, and the Wilderness. At Sailor's Creek, however, he was captured, with his entire force, 6th April 1865. He died 25th January 1872.

**Ewing, JULIANA HORATIA ORR**, writer for children, was the daughter of the Rev. Alfred Scott Gatty and his wife, Margaret Gatty (1809-73), the author of *Parables from Nature*, &c. Born at Ecclesfield, Yorkshire, in 1842, she early began to compose nursery plays for her brothers and sisters, which were performed with her brother, Alfred Scott Gatty, as musical conductor. But she also became proficient in her youth in the modern languages and classical literature. Her nursery stories are said to have suggested to her mother the starting of *Aunt Judy's Magazine* (1866), to which Mrs Ewing became a contributor. After Mrs Gatty's death, she edited the magazine with her sister for a time, and published in it many of her charming stories. These include *Mrs Overthway's Remembrances*, *Jackanapes*, *Jan of the Windmill*, *A Flat Iron for a Parthing*, *We and the World*, *Lob-lie-by-the-Fire*, *Six to Sixteen*, *A Great Emergency*, *Old-fashioned Fairy Tales*, and *The Story of a Short Life*. Mrs Ewing was a graceful writer, and her studies of children, with the varying lights and shadows of child-life, were simple and natural. In 1867 she had married Major Alexander Ewing, the author of a number of translations

from the Turkish and the German. She died at Bath, 13th May 1885. See *Juliana Ewing and her Books*, by Horatia Gatty (1885).

**Ewing**, THOMAS, American statesman, was born in Virginia in 1789, and in 1816 was admitted to the Ohio bar, of which he afterwards became the unquestioned leader. He sat in the United States senate in 1831-37, was secretary of the treasury in 1841, and in 1849-50 organised the newly-created department of the interior, afterwards returning for a time to the senate. He died at Lancaster, Ohio, 26th October 1871.

**Exanthemata** (from a Greek verb, 'to effloresce,' or come out in a rash), a class of febrile diseases (see FEVER) attended by distinctive eruptions on the skin, appearing at a definite period, and running a recognisable course. To this class belong smallpox, chicken-pox, measles, scarlet fever, and, according to some authorities, plague, typhus, &c.

**Exarch** was the title conferred by Justinian on his commander-in-chief and vicegerent in Italy, Narses, who reconquered Italy from the Goths (554). The seat of the exarchs was Ravenna. The extent of the *exarchate* was gradually diminished until it embraced only the country about Ravenna (q.v.). This was brought about by the conquests of the Longobards, whose king, Astulf, in 752 put an end to the Byzantine rule at Ravenna; but in 753 he was compelled to resign the exarchate to Pepin, king of the Franks, who gave it over to the Bishop of Rome, Stephen II.—Other Byzantine viceroys were called exarchs; and the title was conferred on certain bishops (afterwards called patriarchs) and other church dignitaries.

**Excalibur**, the famous mystic sword of King Arthur, which was given him as Merlin promised by the Lady of the Lake, and at his death was flung into the river and caught up by a hand which rose above the waters.

**Excambion** (from the same source as 'exchange'—Lat. *cumbire*, 'to barter'), in Scotland, is the legal name of the contract whereby one piece of land is exchanged for another. The contract usually gives to the parties the right to recur to the original property in case of eviction from the land excambed. Heirs of entail may, with the same consents as are necessary to enable them to disentail, excamb all or any portion of the entailed estate. Where excambed lands are burdened with debts, they are freed of these by the excambion, and burdened with the debts previously affecting the lands acquired in exchange for them. See EXCHANGE (DEED OF).

**Excavators**. These machines have been brought into use in the making of docks, railway-cuttings, canals, &c. Excavators are made of two kinds, each adapted for different kinds of work, although in some cases they work together very effectively. In making a long 'gullet' or cutting, the first to come into operation has the appearance and all the functions of the ordinary steam-crane, such as is used for loading railway trucks, with the exception that it is mounted on wheels to move on rails, and that, instead of the hook on the end of the chain, there is a large and strong plate-iron bucket or 'scoop,' with a very heavy handle or lever to which a second chain is fastened. The lever is heavy enough to counterbalance the scoop when filled with clay. The machine begins by lowering the scoop, and

the two chains are made to push it into the bank until it is full. The suspension chain then lifts the scoop over the wagon, while the chain on the handle lifting it up empties it. The machine now swings round on its centre to renew the operation. The largest size can excavate two cubic yards per minute. As the excavator advances over its rails, those behind are brought to the front. The cutting is made as wide as the arm or 'jib' will reach on both sides of it, which leaves sufficient room for the men to work round it freely, and for wagons to pass. When the cutting has been made the requisite distance forward, the second class of excavator (shown in the engraving) is brought forward to make the cutting wider. The original conception of this is clearly derived from the Dredging-machine (q.v.), which has long been in use in deepening harbours and the mouths of rivers. Its sides are made sloping to an angle of 45 degrees, and on the top of the bank a temporary line of rails is laid a few feet from the edge. The machine is placed on the rails at

Steam Excavator.

the end of the cutting; the jib is lowered until the row of buckets it carries can cut into the clay; these scrape up the bank, reaching the top of it full of soil; they next pass over the machine, and are emptied into the wagons beyond it. The excavator and wagons move forward simultaneously, the latter receiving, in the case of some excavators, a continuous stream of clay equal to about four cubic yards, or two wagon-loads per minute. It will be evident from the foregoing explanation that the first kind of machine is best adapted for docks, and preparing the way in long and deep cuttings for the second kind to follow. It may be said that the first will perform a greater variety of operations, while the second cannot be surpassed in the quantity of material it will remove in a given time. All the movements of excavators are effected by the power of the engine, and two men manage each machine.

**Excellency**, a title now given to Ambassadors (q.v.) as representing not the affairs alone, but the persons of sovereign princes, to whom it was formerly applied.

**Exchange**, in Political Economy, is based on the elementary fact that we are ready to give what we do not want for what we do want, or what we want less for what we desire more. Even in very old communities we find a considerable exchange. As soon as the primitive division of labour into agriculturist, weaver, smith, and carpenter was established, there must have followed a mutual exchange of the produce of these callings. But the early exchange was practically only under very restricted local conditions, for the means of transport and communication were for long not suffi-

ciently developed to convey the staple commodities of industry over very great distances. Indeed, until the means of transport and communication were revolutionised by steam and electricity, all articles that have a considerable weight and bulk in proportion to their value were in general consumed at the place where they were produced. The grain was ground at the village mill, and consumed by those who had produced it; the village smith attended to the iron-work, the village carpenter did the same for the carpentry-work. In the village the wool was spun and woven into cloth, which in general was worn by the people of the locality. The village, parish, or district was an economic unit, within which the business of exchange was for the most part confined.

On the other hand, there had existed from very early times an exchange on a wider scale of commodities which possess a high value in proportion to their bulk and weight, and which are not readily perishable. Gold and silver, precious stones, spices, silk, &c. were the objects of a commerce which was carried on between the Mediterranean countries and the distant East. As civilisation with the corresponding industrial development advanced along the Mediterranean, a more varied and active exchange grew up among the peoples near that great highway of early commerce. Later on it found further scope on the seas and rivers of western and north-western Europe, and along various land routes, especially on those between Italy and Germany. The discovery of America and of the sea-way to India opened up an exchange which has now become universal.

The growth of exchange has simply followed the general social and industrial development. Exchange is based on differences of soil and climate, on differences of social development, on the distinction between town and country, on the growth of the division of labour—in fact, on the wide organic development of the great human society over the different areas of the world. It has particularly depended on the improvement of the means of transport and communication, on the construction of roads and canals, on the development of navigation, and, above all, on the development of steam and electricity. The means of transport are now so perfect that heavy and bulky commodities, such as grain and coal, can be profitably carried half-way round the globe. Exchange has become a dominating principle in economics. Production is only to a very slight degree carried on by the producers for the direct supply of their own needs. Under the large system of industry now prevalent, the outlet for the consumption of any article offered by the producers of it themselves is ridiculously inadequate. Production is carried on for exchange, for a market which may be co-extensive with the world; and through the vast and intricate mechanism of that world-market the consumer obtains the supply for his needs.

The growth of a world-wide exchange has naturally led to a corresponding development of what may be called the instruments and institutions of exchange. First of these is the medium of exchange. In primitive communities we find barter, the simplest method of exchange, still extant; even in the English colonies in North America it was common during the 18th century. The exchange of the civilised world is conducted through the medium of a very elaborate currency. The business of exchange in all the miscellaneous articles known to the civilised world is most largely concentrated in the great markets and exchanges, notably those of London, New York, Paris, Berlin, and Vienna.

Exchange, which up to the end of last century at least was hampered by innumerable restrictions

and regulations, may now be generally described as *free*; it is managed by the free competition of buyers and sellers. But there are very important exceptions and modifications which have been indicated in the article COMPETITION.

In exchange the agreement between buyer and seller is reached by a process of bargaining, which has been called the higgling of the market. It is an adjustment of supply and demand, and ultimately of the interests of producers and consumers. The proportion in which things exchange for each other is their Value (q.v.), but this value is generally expressed in money, the medium of exchange, which is their price. But, while the value is expressed in money, exchange itself is always one of commodities against commodities.

It is an evidence of the prominence attained by exchange in the economy of the civilised world that so high an authority as Whately recommended that the science of political economy should be called *Catallactics* (from Gr. *katallasse*, 'I exchange'). The effect of such a name would be to confound the fundamentals of a science with one of its salient characteristics. Production is a more important department of economics than exchange, while distribution and consumption are fundamental. The chief end of economics is the satisfaction of human needs, production and exchange being alike subsidiary and subordinate to this.

Such is the general doctrine of political economy regarding exchange; but there are some special applications of the word that require notice. Thus, exchange is specially applied to the conversion of the money of one country into its equivalent in the money of another—as by stating the relation which French francs or German marks bear to pounds sterling. It also refers to the difference between the actual value of money, taken by the standard of bullion, in any two places with relation to each other. If in London it costs more than £100 to pay £100 in St Petersburg, the rate of exchange is against the former town, and in favour of the latter; an inhabitant of which will be able to pay a debt of £100 in London with less than £100 worth of bullion in St Petersburg. The process will be best explained by analysing it through means of simple examples. If Thomson & Co. of London buy £100 worth of wine from De la Rue of Paris, and De la Rue, on the other hand, buys £100 worth of cotton goods from Thomson & Co. of London, the two debts, *were there no others between the merchants of the same towns*, would extinguish each other, and there would be no necessity either for transmitting money or drawing bills of exchange. Suppose, however, that it is not De la Rue, but his neighbour Bonchamp who has bought the £100 worth of cotton goods from Thomson & Co., then the debts of all will be settled by Bonchamp paying £100 to De la Rue on Thomson & Co.'s account. Suppose, next, the case of De la Rue being due nothing to Thomson and Co., and Bonchamp being due them only £50, a like sum has to be otherwise found. Van Pradt of Amsterdam is due precisely this sum to Thomson & Co., while either De la Rue or Bonchamp is due the same amount to Van Pradt for a purchase of Gouda cheeses; then it is clear that the several debts can be adjusted among them without the transmission of bullion. It will cost some trouble to adjust the payments, however, and this trouble will have to be paid for. As in paying Thomson and Co. their debt of £100 De la Rue will have to pay for this trouble, the rate of exchange will be against him. If the debt, or any part of it, cannot be met by such an adjustment out of cross debts and credits, it will be necessary for the debtor to send bullion to his creditor; and, this being an expensive process, it throws the rate of exchange

against the debtor who so pays. For instance, if the sum due by the Frenchmen to Van Pradt was only £25 instead of £50, then De la Rue would have had to be at the expense of sending £25 to London in bullion.

No such actual transactions take place in the existing mercantile world, because the accounts in debtor and creditor connected with the three towns above referred to are to be counted in thousands, and ramify into other towns; but the above examples may be held to represent the groups of debtors and creditors, as algebraic signs represent quantities. The individual merchants in one trading town have no idea how the surplus of debit or credit may lie between them, far less can they tell how it may be adjusted by debits and credits in other towns; but, through the agency of bankers, bill-discounters, and other persons who deal in money, the relations of all trading-places towards each other are in a constant state of shifting and adjustment; and any one who has to pay a debt in any trading-place can find out how much he has to give to get that debt paid, and can pay it accordingly. When, through the operation of these complicated transactions, you require to give more than £100 in London to get that amount paid in Paris, then the rate of exchange is against London, and is in favour of Paris, where less than £100 in cash will pay a debt of £100 in London. The difference will generally depend on the difficulty of adjusting questions of debt and credit throughout the field of European commerce in such a manner as to get the debt paid. If it cannot be paid by adjustment, then bullion must be sent; and thus it is generally said that the rate of exchange against any place is limited by the charge of transmitting bullion to it. The rate of exchange is liable to be brought to a level also by commercial exportation and importation, since, whenever it is expensive to get money sent to a country, goods may be sent to that country to compensate the debt. In the general circle of transactions of this kind, the state or town which has the largest amount of transactions will have the largest number of debtors and of creditors, and will thus afford the chief facility for each compensating the other. For this and other reasons London is the centre of the money-market, where all the debts and credits in the world may be said to meet and extinguish each other (see BILL OF EXCHANGE). While the old notions about the Balance of Trade (q.v.) existed, it was supposed that the nation which the exchange was against was going to ruin, while that which it was in favour of was prospering through the other's loss. Such general statements must be tested by a comprehensive analysis of all the relevant facts. Gold-producing countries find bullion their most advantageous export, and the same is the case with countries into which gold has flowed in excess.

**Exchange**, a term applied to buildings or places of resort for merchants. The name *Bourse* (Lat. *bursa*, 'purse') is applied in France and Belgium to a resort of this kind; and in Germany, *Börse*.

Exchanges originated in the commercial cities of Italy, Germany, and the Netherlands; and Sir Thomas Gresham, who had resided as English agent at Antwerp in 1550, chose the Bourse of that city as a model for the Royal Exchange of London. Gresham's Bourse, for so it was originally called, was built on Cornhill in 1566-67. It consisted of a quadrangle with an arcade; above was a corridor (called the *pawn*) with stalls, for the sale of wares; outside were shops. On January 23, 1571, the Bourse was ceremoniously opened by Queen Elizabeth, who, by herald and trumpet,

caused it to be proclaimed 'The Royal Exchange.' This first exchange of London was almost entirely destroyed by the great fire of 1666. A new exchange was forthwith erected on the spot, and opened in 1669; but it also was destroyed by fire, in 1838. The foundation-stone of the third exchange was laid in 1842; and completed at a cost of £180,000, from the designs of Tite, it was opened October 28, 1844, by Queen Victoria.

The term exchange seems to have been naturally adopted from the circumstance that buying and exchanging of merchandise, and also exchanging and paying away of money, formed the chief object of concourse. In the present day, early intelligence in matters affecting commerce and public finance forms a principal attraction of this kind of resort. Although open daily, there are usually certain days and hours of meeting when the throng is considerable. The meeting is familiarly called 'Change.' The two great days of meeting at the Royal Exchange, London, are Tuesday and Friday, and the busiest time is from three to four o'clock.

In London there are several other exchanges, but for special purposes; among these are the Corn Exchange in Mark Lane, the Coal Exchange in Lower Thames Street, the Hop and Malt Exchange in Southwark, the Hide and Skin Exchange or Market in Bermondsey, and the Stock Exchange, near the Bank of England. Amongst the exchanges in the large towns of England and Scotland, those of Manchester, Liverpool, and Glasgow are specially noteworthy. There are exchanges, many of them for special purposes, in Augusta, Baltimore, Boston, Brooklyn, Buffalo, Charleston, Chicago, Detroit, Louisville, New Orleans, New York, Philadelphia, Richmond, St Louis, San Francisco, and other cities of the United States. See CHAMBER OF COMMERCE, STOCK-EXCHANGE.

**Exchange, DEED OF**, in English law, a common law assurance, whereby persons severally seized of lands mutually grant them in exchange, each his own land for that of the other. The two subjects must be of the same nature, as lands for lands, chattels for chattels, but not real for personal estate. The parties must take an equal estate—thus, an estate in fee cannot be exchanged for an estate tail; and the word 'exchange' must be used. There must also be entry, and if either party die before entry his heir may avoid the transaction. Exchange must now be made by deed, but this form of conveyance is seldom used, the same purpose being effected by two separate deeds of grant. A mutual warranty and right of entry was formerly implied in an exchange. This effect of the deed has been taken away by an Act of 1848. By the Common Enclosure Act of the same year the commissioners are empowered to make exchanges for the better carrying out of the purposes of the act. A deed of exchange closely resembles in its particulars an Excambion (q.v.) in Scotland. The law as to exchange in most of the American states is founded on and similar to that of England.

**Exchanges, MILITARY**, are certain arrangements made between officers of the British army to enable them to change their regiments or stations. Officers exchanging must be of the same rank. Artillery, engineer, marine, or departmental officers can only exchange in their respective corps, and do not lose seniority by doing so. Officers of other branches may exchange with each other, but, if they change regiments, go to the bottom of the list of officers of corresponding rank. Exchanges are ordinarily arranged by the Army Agents (q.v.), and others who make it their business to carry them out; but each exchange

requires the sanction of the commander-in-chief, and of the two commanding officers affected by it. Considerable sums are often paid by one officer to another to induce him to exchange.

**Exchequer.** The ancient Exchequer in England was a branch of the King's Court, in which sheriffs and others were held to account for the revenues they received, and questions relating to the royal revenue were decided. The name *exchequer* (Fr. *eschiquier* in the 12th century, from *eschec*, 'check' at chess) was derived from the checkered tablecloth on which money was counted, a practice which was continued in the Scottish Court of Exchequer down to modern times. In England the financial department of the court was called the receipt of the Exchequer. The Chancellor of the Exchequer was originally appointed as under-treasurer, to check the proceedings of the Lord High Treasurer (see TREASURY). He sat as a judge on the 'equity side' of the Court of Exchequer, or on the rehearing of cases in which the other judges of the court were equally divided in opinion. But in modern times his position has been that of first finance minister of the crown; the office is sometimes held by the prime-minister, when he is a member of the House of Commons. The last case in which the Chancellor of the Exchequer sat as a judge was in 1735; the decision then given by Sir Robert Walpole is said to have caused great satisfaction; but his successors have not figured among the judges except on occasions of state and ceremony. The receipt of public revenue now belongs to the several revenue departments, under the supervision of the Exchequer and Audit Department and the Treasury. See Madox, *History of the Exchequer* (1711; new ed. 1769). For *exchequer tallies*, see TALLY.

The Court of Exchequer was originally, as has been stated, a revenue court, but it obtained a general common-law jurisdiction by means of the writ of *Quominus*, wherein it was set forth that the plaintiff, by reason of the wrong done to him by the defendant, was deprived of the means of discharging his debt to the crown. This fiction was abolished in 1832. The ordinary judges of the court were the Chief Baron and three puisne Barons, so called, according to Selden, 'because they were anciently made of such as were barons of the kingdom.' The equity jurisdiction of the court is said by Coke to date from a statute of 1542; it was transferred to the Court of Chancery in 1842. In 1875 the Exchequer became a division of the High Court of Justice. The Exchequer Division is now merged in the Queen's Bench Division; the office of Chief Baron has been abolished, and no judges are now appointed with the title of Baron. See COMMON LAW, and Coke's *Fourth Institute*.

The Court of Exchequer Chamber was formerly a court of all the judges in England assembled for decision of matters of law. The ordinary jurisdiction of the Court of Exchequer Chamber was as a court of error, in which capacity it revised the judgments of the three courts of common law; the decisions of each court being revised by the judges of the other two. An appeal now lies from each division of the High Court of Justice to the Court of Appeal.

In Scotland, before the Union, the Exchequer was the king's revenue court. It consisted of the treasurer, the treasurer-depute, and as many of the lords of Exchequer as the king was pleased to appoint. The Scottish Court of Exchequer was continued by the 19th article of the treaty of union, until a new court should be established, which was effected in 1707. A privative jurisdiction was conferred on the court as to questions relating to revenues and customs of excise, and as

to all honours and estates real and personal, and forfeitures and penalties arising to the crown within Scotland. But questions of *title* to lands, honours, &c. were reserved to the Court of Session. The judges of the court were the high treasurer of Great Britain, the chief baron, and four other barons; and English barristers as well as Scotch advocates were allowed to practise in the court. In cases of difficulty, and where there was a collision of jurisdictions, it was formerly not unusual to hold conferences with the barons; and the form of desiring the conference was to send the Lord Advocate, and, in his absence, the Solicitor-general, to request a meeting, though it has been doubted whether they were bound to carry the message. In 1832 it was enacted that successors should not be appointed to such of the barons as should retire or die, and that the duties of the court should be discharged by a judge of the Court of Session. And in 1886 the Court of Exchequer was abolished, and the jurisdiction transferred entirely to the Court of Session.

The Court of *Exchequer Chamber* in Ireland was established in 1800, but was abolished as an intermediate Court of Appeal between the Irish Courts and the High Court in England.

**Exchequer Bills**, bills issued at the Exchequer under the authority of acts of parliament, as security for money advanced to the government. They contain an engagement on the part of the government for the payment of the principal sums advanced, with interest. These bills form the chief part of the unfunded debt of the country. They were first issued in the reign of William III., in the year 1696, and were drawn for various amounts from £100 to £5. At that time they bore interest at the rate of 3d. per day on £100. The interest was reduced to 2d. during the reign of Anne. During the war 1793-1814, the rate of interest was usually 3½d. At present it is generally from 1½d. to 2½d. per £100 per diem. Holders of these bills are exempt from all risk, except that arising from the amount of premium or discount they may have given for them. The bills pass from hand to hand as money, and are payable at the Treasury at par. They may also be paid to government in discharge for taxes. When it is intended to pay off outstanding Exchequer bills, public notice is given by advertisement. The advances of money to government by the Bank of England are made on Exchequer bills. These bills are a convenient means whereby government can meet a sudden demand for unusual expenditure. The unfunded debt consists of Exchequer Bills, Exchequer Bonds, and Treasury Bills; the total unfunded debt outstanding at 31st March 1888 was £13,795,200. See NATIONAL DEBT.

**Excise**, the name of a tax on commodities, from the Latin *excisus*, 'cut off,' as being a portion of the value of the commodity cut off and set apart for the revenue before the commodity is sold. This is not its actual nature, however, for the manufacturer who looks to a profit on his product does not give part of the value to the revenue; he merely counts the tax as part of his expenditure, or, in other words, includes it in the price, the tax being really paid by the consumer. An inland tax on commodities sold and bought for consumption in the country is a very ancient one, but it has generally appeared in the simple shape of a toll or *octroi* on goods brought to market. The complicated arrangement for officially watching the process of a manufacture, for the purpose of seeing that none of the dues of the revenue are evaded, is of comparatively modern origin. It was first introduced into England, upon the Dutch model, by the Long Parliament, which established an excise on liquors in 1643, and in subsequent years on articles of

food, salt, silk and stuffs, and other commodities in general use. Though unpopular, the excise in some form or other has ever since continued to be a material element in the taxation and revenue of Britain. In the earlier part of the 18th century Sir Robert Walpole entertained the notion of enlarging its productiveness, while mitigating its proportional pressure by the bonding system, which suspends the exaction of the duty until the goods are sold, and thus leaves the manufacturer with all his capital to be devoted to production (see BONDED WAREHOUSES). But the rumour of an enlargement of the unpopular excise duty created a general excitement, and the memorable cry of 'Liberty, Property, and No Excise,' compelled Walpole to abandon his project.

An excise, when compared with other taxes, has its good and its bad features. It is a method of extracting money for national purposes from personal expenditure on luxuries, and is especially serviceable when received from those luxuries the use of which in excess becomes a vice. On the other hand, it renders necessary a system of inquisitorial inspection not very agreeable to a free people, and open to abuse and fraud; while at the same time excessively high duties, and duties on commodities strictly of domestic manufacture, lead to smuggling and all its demoralising consequences. The evils of an excise were formerly aggravated by the practice of farming the duties—i.e. by letting them to the highest bidder, whose interest it became, like any other contractor, to make the greatest possible profit by his speculation, and consequently to exact the duties in the most rigorous manner. In every well-regulated revenue system it is, of course, only fair to all parties that the duty, as the law lays it on, should be fully exacted; but in the age of farming the arrangements were all slovenly, and there was much latitude of power in the hands of the farmers. The farming system became very oppressive in France, especially in the *gabelle* or excise on that necessary of life, salt. It is a curious fact, however, that when the farming of the excise was abolished in Scotland by the Union the people grumbled, saying they were easier under the farmers, their own neighbours, who acted on the principle of 'live and let live,' than under the officers sent down from England, who rigorously collected the impost.

An excise works most easily when it is laid on some commodity manufactured on a large scale. In a great distillery the excise officer is almost a portion of the establishment; he has an eye on every step of the process, with the object of seeing that the commodity does not get into the market without government obtaining its proper share—sometimes far the greater part—of the market price. The social influence of such an arrangement is very different from that of the old candle and salt duties, which made it the function of the exciseman to pounce on a farmer melting the surplus tallow of the last killed sheep, or on a fisherman boiling sea-water to procure salt for his potatoes. The manufacturer, however, though he has the benefit of the bonding system, feels the excise regulations to be a considerable drag and hindrance in his operations, since there are numerous minute operations which he cannot perform without sending special notice to the excise department, or having an officer actually present. This renders it necessary, too, that all the steps of the process should not merely be defined as between the manufacturer and the officer, but should be set forth in an act of parliament; and hence deviations for the purpose of economy, or by way of experiment, become difficult, and sometimes impracticable. As difficulties with which the pro-

ducer has to contend, these things require him to lay on the selling price of the commodity a larger addition than the actual amount of the duty. This objection, however, is less potent than it formerly was, for the introduction of machines and special apparatus, such as alcoholometers, saccharometers, &c., has greatly facilitated the collection of excise duties.

No method of taxation requires a nicer adjustment to the social condition of a country than an excise. While it is now admitted that necessities of life should be free, yet some form of tax upon consumption is the only method by which certain classes of the people can be made to contribute their share to the revenue of the country. But for the excise and customs dues on beer, spirits, and tobacco, and some licenses, many persons would evade all share in the national burden. In England, in the year 1746, a duty of 20s. a gallon was laid on spirits, with the view of suppressing the vice of drunkenness, which, however, it greatly increased, for the law became a dead letter, and the smuggler fully supplied the market, although within the two years in which the law was in force no fewer than 12,000 persons were convicted of offences against the act. In Scotland, the duty, which was 5s. 6d. a gallon, had to be reduced in 1823 to 2s., on account of the prevalence of smuggling—half the consumption of the country, in fact, paying no duty. The duty has since then been gradually raised, until it now amounts to 10s. a gallon, forming a large source of revenue. The productiveness of the spirit duty, and a better understanding of the true principles of taxation, has led to the gradual removal of many excise duties, as, for instance, on salt, candles, leather, glass, soap, paper, &c. The malt-tax was transferred to beer in 1880.

In 1849 the excise department was amalgamated with that of stamps and taxes to form the Board of Inland Revenue; and many changes have been made, both as to the articles taxable and in the organisation of the excise system. The only items on which excise duties are now charged are spirits, beer, tobacco, chicory, and the passenger receipts of railway companies. But various taxes of the nature of license-duties for following particular pursuits are collected in the excise department; also several items chargeable before 1869 as assessed taxes. License-duties must be taken out yearly by auctioneers, appraisers, brewers, maltsters, distillers, makers of vinegar, victuallers, sellers of beer, spirits, and wine, sellers of playing-cards if also makers, hawkers, pedlars, horse-dealers, house-agents, tobaccoists, pawnbrokers, dealers in sweets, and dealers in patent medicines. Game-licenses, gun-licenses, and licenses for male-servants, horses, dogs, carriages, and the use of armorial bearings come under the same department. The whole excise revenue of the United Kingdom in the fiscal year ending 31st March 1858 was £17,901,545; 1868, £20,190,338; 1878, £27,710,514; and 1888, £25,620,000, when the cost of collecting it was £1,771,785. The principal items of the receipts in the last-named year were: Beer, £8,711,532; spirits, £13,028,204; railway passengers' duty, £314,933; and licenses. Among the latter the chief contributors were beer and wine dealers, £186,574; dog-licenses, £354,278; carriages, £549,525; armorial bearings, £74,526; male-servants, £136,287; game, £179,143; gold and silver plate, £47,919; gun, £86,317; pawnbrokers, £35,722; hawkers and pedlars, £26,942; brewers, £19,280; auctioneers and appraisers, £79,300; spirits (distillers), £4242, (dealers), £121,194; publicans and grocers licensed to sell liquor, £1,485,936; tobacco, £84,855; wine and sweets, £67,366. The budget estimate of the

excise receipts for the fiscal year 1888-89 was £25,505,000, and the estimated cost of collection £1,807,629. In introducing this budget, Mr Goschen proposed a new scale of carriage-duties, to institute what was called a 'Wheel and Van Tax,' and to put a special impost on 'pleasure-horses.' This proposal, owing to the opposition it excited, was withdrawn, as was also a proposal to repeal the hawkers' license. That license, however, was in 1888 reduced from £4 to £2. According to the present organisation of the excise department, the United Kingdom is divided into collections, each under a collector; the collections are subdivided into districts, each under a supervisor; and these into divisions, each under division-officers and ride-officers. The efficiency with which these officials discharge their duties secures a very complete payment of taxes, and their manner of dealing with the tax-payers leaves a *minimum* of just ground for complaint. The old feeling of objection to the excise as a 'foreign system' has completely worn away, and the tax is now probably as popular as any impost is ever likely to be. To put it otherwise, the excise is not disliked so much as the income-tax. See the articles BEER, WHISKY, &c.

In the United States, the word excise is not officially used, the corresponding title being 'internal revenue.' This is raised mainly from whisky, tobacco, and malt liquors; other items being the tax on banks and bankers, and on oleo-margarine. Stamps ceased to be a source of revenue after 1883. The total internal revenue of the United States was \$309,226,813 in 1866, \$116,700,723 in 1876, \$116,805,936 in 1886, \$118,823,391 in 1887, \$124,296,872 in 1888; while for 1889 the estimate was \$125,000,000.

**Excitants.** See STIMULANTS.

**Exclusion Bill,** a measure brought forward by Shaftesbury in 1679 to exclude the Duke of York, afterwards James II., from the succession to the throne, on account of his avowed Catholicism. It thrice passed the Commons, and as often Charles II. resorted to a dissolution, till, after March 1681, he ruled without parliamentary control.

**Excommunication.** The word 'excommunication' denotes exclusion, whether temporary or permanent, from fellowship in religious rites, involving also, where participation in such rites is required in the civil order, privation of the rights of citizenship. It is not peculiar to the biblical religions, but is found in most of the systematised cults, whatever be their origin. Thus, Caesar describes its operation amongst the Gauls, stating that contempt of the decisions of their judges was visited with interdiction from the sacrifices. 'This is a most severe penalty with them. For those so interdicted are counted as sinful and wicked; all keep aloof from them, and avoid approaching or addressing them, lest they should incur some injury by contact; they are granted no right which they claim, nor is any honour bestowed upon them' (*Bell. Gall.* vi. 13). The absence of any remark as to a corresponding usage amongst the Romans and Greeks of the time is enough to show that Caesar was not familiar with the practice; but slight indications are discoverable of analogous usages, so far as regards exclusion from common acts of worship, amongst which the Latin word *profanus*—signifying that which is 'outside the temple'—may be specially cited. The clearest analogy, however, to the Christian discipline of excommunication is that furnished by the Rabbinical eode. This is ultimately based on the legislation of the Pentateuch, which excluded the ceremonially unclean, as well as offenders of a graver kind, both

from religious and civil fellowship (*Lev.* xiii. 46; *Numb.* v. 2, 3; xii. 14, 15); and the penalty is recorded in *Ezra*, x. 8, as enforced against such Jews of the captivity as disobeyed the proclamation to assemble at Jerusalem. The offender first received a public admonition, and seven days later, if he did not make satisfaction, the lesser excommunication, *Niddui*, was pronounced against him, whereby he was isolated during thirty days from contact with all save his wife and children, being obliged to keep at least 4 cubits' distance from all others; and although the sentence did not technically include expulsion from the synagogue, yet this provision practically enforced it. At the expiration of the 30 days, a second term of like duration was enjoined in case of continued impenitence; and the contumacious were then visited with the greater excommunication of *Cherem*, which excluded both from the synagogue and from all social intercourse, and the offender was treated as a leper. These two grades of excommunication were the only ones anciently in use; but the later Rabbins added a third and severer one, styled *Shammatha* or *Anathema Maranatha*, which was lifelong, attended with solemn imprecations, and sometimes entailing forfeiture of goods.

The Christian system of excommunication is based doctrinally on the precept of Christ (*Matt.* xviii. 15-18) and on the precepts and practice of St Paul (*Rom.* xvi. 17; *1 Cor.* v. 3-5, 11; *2 Thess.* iii. 14) and St John (*2 John*, 10, 11); while its practical method was borrowed from the synagogue, and formulated certainly by the 3d century, perhaps as early as the 2d. It was primarily, as the word denotes, exclusion from communion in the eucharist and the *agape* or love-feast, including also suspension from office in the case of clerical offenders; and it was distinguished as major and minor, each having various degrees of severity. Thus, the lightest form of excommunication permitted the offender to join in all acts of public worship except to make oblations and actual reception of the eucharist; the grade next below was not suffered to be present during the latter part of the liturgy, but only during the preliminary prayers and the remaining public offices; below this class again came those who were excluded entirely from the prayers, but permitted to enter church to hear the Scriptures read and sermons preached; while the lowest grade of all was refused permission to enter church, being obliged to remain outside the doors until the expiry of their term of penance. Similarly, the major excommunication, besides its exclusion of offenders as well from social intercourse as from all participation in church fellowship and ordinances, which applied in all cases, had also the graver form of anathema, fulminated against the most obstinate offenders, and chiefly such as taught or abetted heresy, or, at a somewhat earlier date, those who had lapsed in time of persecution, and had either sacrificed to idols or obtained certificates alleging them to have done so. The controversy as to the possibility of readmitting such persons to communion at all—denied by the Novatianist or rigorist school—was one of the most serious which agitated the church in the 3d century; and, though the milder course ultimately prevailed, yet even the moderate party insisted upon very severe and prolonged penalties, seldom pardoning the offender till the very close of life, unless at the personal intercession of a martyr. Notice of such greater excommunication was sent by circular to all churches in the case of clerical offenders or laics in official positions, to insure the universal incidence of the penalty; and intercourse with any one underlying it involved the same punishment as the original offence, the lesser excommunication being

incurred *ipso facto*, and the greater by persistence in such intercourse after admonition. At a very early date the aid of the civil power was invoked in support of the spiritual sentence, not only by preventing resistance thereto, but by superadding a temporal penalty. Thus, the fifth canon of the Council of Antioch in 341, after enacting that any cleric setting up a schismatical place of worship shall be deposed for life, adds: 'And if he persist in troubling and disturbing the church, let him be corrected by the civil power as a seditious person.' And in the third Council of Carthage in 397 a canon (xxxviii.) was passed to petition the governor of the province to remove an intruding bishop who had disregarded the ecclesiastical censures passed upon him; which was embodied later in the general code of the African Church, as well as two others of a like nature (lxvii. and xciii.) directed against the Donatists. In the Theodosian Code there is a law imposing a fine of ten pounds of gold upon all heretical persons conferring or receiving ordination, further confiscating the place where the act occurred, if done with the knowledge and assent of the owner; and many such enactments appear in later history, such as the decree of Childbert in 596, the Capitularies of Pepin in 755, and the Constitutions of Lothar I. in 825, whereby excommunicated persons were put to the ban of the empire; while a constitution of Frederick II. in 1220, alleging that the material sword is appointed for the aid of the spiritual sword, enacts that, in the event of excommunicated persons not making satisfaction within six weeks from the sentence, the civil ban is to issue thereupon, and not to be revoked until the previous removal of the excommunication. The theory that the spiritual sword might be turned against the civil power itself, and that excommunication deprived sovereigns and other magistrates of their authority, voiding, indeed, all civil rights, is peculiar to Latin Christianity, and is a development of the Hildebrandine era and policy (see ALLEGIANCE), first put into actual execution by Gregory VII. against the Emperor Henry IV. in 1076, and again in 1080, renewed in 1084 by Urban II., and in 1102 by Paschal II.; and later against the Emperor Philip of Swabia, and in favour of his competitor Otto IV. by Innocent III. in 1210. It is compendiously stated thus by Cardinal Francis de Toledo (1532-96) in his *Instructio Sacerdotum*, a work of much repute, recommended by Bossuet: 'An excommunicated person cannot exercise an act of jurisdiction without sin; nay, if the excommunication be publicly made, his sentences are null' (lib. i. chap. 3). Two latest instances of the kind are the excommunication of Napoleon I. by Pius VII. in 1809, and that of Victor Emmanuel II. by Pius IX. in 1870. But the omission of their names in these documents, which are vaguely and indefinitely fulminated against enemies and oppressors of the holy see, barred the full operation of the sentences in canon law, and left the question of allegiance untouched.

In the actually current discipline of the Roman Catholic Church a distinction is drawn between such sentences of excommunication as are incurred *ipso facto* (technically known as *lata sententia*) and such as do not take effect till after the formal sentence of an ecclesiastical court (called *ferenda sententia*); and those subject to such sentences are distinguished as *tolerati* and *non-tolerati*, the former of whom are still eligible for social and civil intercourse, while the latter are absolutely excluded from all such communion, as well as from the ordinances of religion. In theory the right to pronounce the greater excommunication is limited to the pope solely, as also the power to absolve therefrom; but in practice this authority is con-

veyed to all bishops in their quinquennial faculties, for local exercise within their dioceses, and by them to the clergy under their jurisdiction, so far as regards absolution, but not for pronouncing sentence, which is never committed to any one below the rank of bishop or judge. In most Roman Catholic countries, if excommunication involves any civil disabilities, it cannot be published without the sanction of the civil power, and in some of them there is an appeal to the law-courts on the merits, to obtain fresh examination of the case at the hands of the ecclesiastical authorities. It is a mistake to ascribe to Roman Catholics the doctrine 'that excommunication may be pronounced against the dead.' The contrary is expressly laid down by all canonists (Liguori, *Theologia Moralit*, lib. vii. n. 13, 1). In the cases in which this is said to have been done, the supposed 'excommunication of the dead' was merely a declaration that the deceased individual had, while living, been guilty of some crime to which *excommunication* is attached by the church laws. Roman Catholic writers, moreover, explain that the civil effects of excommunication in the medieval period—such as incapacity to exercise political rights, and even forfeiture of the allegiance of subjects—were annexed thereto by the civil law itself, or at least by a common international understanding in that age. Examples are alleged in the law of Spain, as laid down in the Sixth Council of Toledo, a mixed civil and ecclesiastical congress (638); in the law of France, as admitted by Charles the Bald (859); in the Saxon and in the Swabian codes; and even in the English laws of Edward the Confessor; all which, and many similar laws, proceed on the great general principle of these medieval monarchies—viz. that orthodoxy and communion with the holy see were a necessary condition of the tenure of supreme civil power; just as by 1 Will. and Mary, sect. 2, chap. 2, profession of Protestantism is made the condition of succession to the throne of England. Hence, it is argued, the medieval popes, in excommunicating sovereigns, and declaring their subjects released from allegiance, did but declare what was, by the public law of the period, the *civil* effect of the exercise of what in them was a *spiritual* authority.

By the discipline of the Roman Catholic Church, kings or queens, and their children, are not included in any general sentence of excommunication, unless they be specially named.

Certain 'reserved cases' are limited to the pope alone, and are enumerated in the brief 'Apostolicæ Sedis,' promulgated by Pius IX. in 1869, which also contains a list of those sentences, *lata sententia*, now in force within the Roman Church; but an ordinary priest is permitted to absolve those at the point of death from even the reserved excommunication.

The oriental discipline is much less elaborate, and more nearly accords with ancient practice; but the distinction between the greater and lesser excommunication is retained, and no fewer than 116 offences, involving various degrees of excommunication, are specified in the office-books, ranging from twenty years' exclusion, for such crimes as murder or magical practices, down to bigamy, with its penalty of one year and merely ceremonial disqualifications, yet briefer in effect. The greater anathema is fulminated yearly throughout the Eastern Church on Orthodoxy Sunday (first Sunday in Lent) against about sixty forms of heresy, for the most part extinct; but in the Russian Church they have been cut down to twelve still prevalent types of opinion.

In the Church of England the medieval practice conformed in the main to the current western usage, save in this one important respect, that an excommunication *ipso facto* was not really in

operation; for though the term occurs frequently, yet what it denotes is only that, given a certain offence, excommunication must follow as the penalty, but a declaratory sentence of a competent court must precede the actual excommunication.

Various civil disabilities attended excommunication, and were continued after the Reformation, such as inability to hold a benefice, to practise as an advocate or attorney in the courts, to be admitted as a witness, and to receive Christian burial. By a canon of 1597 the ordinaries were to provide for the public denunciation monthly in the cathedral of the diocese and the parish church of the offender, in all cases where an excommunicated person had not made satisfaction and obtained absolution within three months after incurring sentence; and this was embodied in the canons of 1604 (lxv.), with the alteration to a half-yearly denunciation, but with the further provision that those present should be induced to apply for a writ *De excommunicato capiendo*, 'thereby to reduce them to due order and obedience.' This writ was issued by the Court of Chancery on the application of the diocesan, and addressed to the sheriff or other officer, and warranted the imprisonment of those arrested under it. The disabilities attending excommunication were abolished for England by the Act 53 Geo. III. chap. 127, and for Ireland by the 54 Geo. III. chap. 68; while all remaining penalties against persons dissenting from the worship and doctrines of the Church of England were repealed by 7 and 8 Vict. chap. 2, and 9 and 10 Vict. chap. 59. The most notable exercise of the power of excommunication in the modern Anglican Church was when Bishop Gray, as Metropolitan of Capetown, deprived and excommunicated Bishop Coleenso of Natal in 1863, which sentence, approved by the Convocations of Canterbury and York, the General Convention of the American Episcopal Church, the Episcopal Synod of Scotland, and the Provincial Council of Canada (as well as by a large majority of the bishops assembled at the first Lambeth Conference in 1867), was reversed by the Judicial Committee of Privy-council in 1865, on the ground that the crown had no power to erect the see of Capetown into a metropole, nor to give Bishop Gray the coercive jurisdiction on which he had relied as empowering him to try one of his suffragans and pass sentence upon him.

In the Established and other Presbyterian churches of Scotland, the lesser excommunication, involving deprivation of all 'sealing ordinances,' can be pronounced by the kirk-session. The greater excommunication can be pronounced by authority of the presbytery only; it is now very rarely heard of, and since 1690 it does not carry with it any civil consequences.

A very singular kind of excommunication is that connected with the usage of *tabu* amongst the islanders of Polynesia. *Tabu* is a species of interdict which may apply to persons or things; in the latter case making any use of the interdicted article, or even contact with it, unlawful and penal; in the former cutting off the interdicted person from all intercourse or contact with others, and even prohibiting him to use his hands to feed himself; a chief or noble being allowed a servant, also put under *tabu*, to feed him, and a man of lower rank being obliged to pick up his food with his mouth only, like a beast.

Islam forms an exception to the almost universal incidence of the practice of excommunication. Under the Moslem code every religious offence carries with it a temporal penalty, such as fines, scourging, stoning or other mode of death, and only in this last manner can an offender be cut off

from the congregation. See BELL, BOOK, AND CANDLE; also INTERDICT.

**Excretion.** See SECRETION; and for the excretory organs, see RESPIRATION, SKIN, KIDNEY, URINE, &c.

**Exc.** a river of Somerset and Devon, rising in Exmoor, and flowing 54 miles south-eastward and southward to the English Channel at Exmouth. The lower 5 miles form a tideway a mile broad at high-water, with wooded and picturesque shores, and navigable for large vessels. An ancient canal connects the estuary with Exeter (q.v.). The chief tributaries of the Exc are the Barle, which also rises in Exmoor, and is 24 miles long, Batham, Loman, Culm, and Creedy. The Exc passes Dulverton, Bampton, Exeter, and Topsham. The greater part of its course is through wooded and romantic vales.

**Execution,** in Law, is the act of completion or carrying into effect. Thus a writ is executed by obeying the instructions contained in it; a Deed (q.v.) is executed when it is signed, sealed, and delivered; a power is executed when it is exercised; a judgment of a court is executed when it is enforced. Judgments are usually enforced by writs of execution, which direct the officers of the law to do what is necessary, or to compel a defendant to perform some act. The term 'execution' is used now technically to denote execution to recover a debt—the kind that occurs most usually in practice. In Scotland, the term execution is also applied to the written attestation under the hand of the executive officer that he has carried his warrant into effect, as by serving a summons or giving a citation. It corresponds to the *allidavit* of service of writ in England.

**Execution,** in civil law. In civil cases the common law of England allows four different writs to issue against refractory debtors—viz. a *fi. facias* (called commonly a *fi. fa.*), a *capias ad satisfaciendum* (*ca. sa.*), *levari facias*, and *elegit*. These writs issue from the court of the Division in which the proceedings are grounded, and are addressed to the sheriff of the county. By a *fi. fa.* the goods and chattels of a debtor may be attached. This writ lies against all proprietors, peers, &c. A writ of *ca. sa.* is directed against the person of a debtor. It does not lie against privileged persons. Under this writ, the sheriff may imprison a debtor, and detain him until the debt has been satisfied. A writ so stringent in its effect is regarded by the law as the last remedy; hence, when a *ca. sa.* has been issued, no other writ can proceed against the debtor. But if a *fi. fa.* has been first issued for a part of the debt, a *ca. sa.* will still lie for the remainder. By recent statutes, a *ca. sa.* cannot be issued to imprison for debt unless fraud or contempt of court is involved. A *levari facias* is now seldom used. It is directed against a man's goods and the profits of his lands. The writ of *elegit* is of very ancient date (see ELEGIT). In the Chancery Division of Court, execution against the estate is effected by writ of *fi. facias* or writ of *elegit*. Execution against the person is by writ of attachment. Should this latter writ be returned *non est inventus*, the party prosecuting has it in his option to take out a writ of sequestration of the estate, with issues of course, or to obtain an order for the serjeant-at-arms. An attachment does not lie against a peer or other privileged person, but an order called a sequestration *nisi* is issued. In cases of contempt, the High Court in each division has also the power to order personal commitment. In all cases execution may issue immediately, each writ being renewable after a year, within six years; but the court or judge can stay execution to a time fixed—or subject to conditions.

In the United States, the law of execution is complicated by the rules which define the local jurisdiction of district and state courts and of the United States courts. The writs of execution in use are *fi. facias*, *levari facias*, &c.; the writ of *elegit* is now little used. In some states the homestead and other property of a debtor are exempted from execution; and congress has enacted that execution issuing out of United States courts must follow the provisions of these local laws.

In *Scotland*, execution for debt, or, as it is technically expressed, diligence in execution, is either real or personal; by the former, the debtor's lands may be attached; by the latter, his person and his movables. In order to entitle a creditor to use diligence against the person or estate of his debtor, the debt on which the diligence proceeds must be duly constituted by a liquid document, or by a decree, or by an action in which decree is sought. In this latter case, the law in peculiar circumstances allows diligence on the dependence, in order that a party may not be deprived of his remedy during the currency of the action, but such diligence depends for its effect upon the judgment in the cause. In the case of bonds and other instruments registered for execution (see *REGISTRATION*), the law allows summary diligence to proceed; that is to say, execution may proceed without the need of further application to the court. Diligence against heritage includes inhibition, which is a writ passing under the signet, and prohibiting the debtor from contracting any debt which may become a burden on his heritage to the prejudice of the inhibitor's debt; Adjudication (q.v.); Ranking and Sale, a process of law by which the heritable property of an insolvent is judicially sold, and the proceeds divided among his creditors; and Poining of the Ground, which is an action proceeding on a heritable security, and attaching all the goods on the lands over which the security extends. Personal diligence is (1) by Horning and Caption, where letters of horning—i.e. letters running in the sovereign's name, and passing the signet—are issued instructing messengers-at-arms to charge the debtor to pay, and on his failure a caption or warrant for his apprehension is granted; (2) by the simpler form of Warrant to Charge under the Personal Diligence Act, which replaces the old process of horning and caption; (3) by Arrestment (q.v.).

**Execution**, in criminal law, is the infliction on criminals of the punishment of death in conformity with legal decree (see *CAPITAL PUNISHMENT*). The modes of execution have varied greatly, both in the progress of time and in different countries. On the whole, the manner of executing the death-penalty, as of decreeing and inflicting punishment in general, has tended to grow more humane with the advance of civilisation. Among the Jews a frequent form of execution was stoning, while burning alive appears (*Genesis*, xxxviii. 24) to have been practised in their patriarchal history, and is sanctioned by Mosaic law. Casting from a rock was a mode recognised by the Jews and the Twelve Tables of the Romans. Under the Roman republic vestal virgins violating their vows of chastity were buried alive, and in the time of Paul crucifixion, burning, and decapitation were the chief modes of execution. Crucifixion (see *CROSS*) was in use likewise among the Assyrians, Persians, Egyptians, Carthaginians, and Greeks. Constantine, on his adoption of Christianity, abolished crucifixion in the Roman empire. The Italians of the middle ages, however, crucified some of their prisoners of war. Another revolting form of execution among the Romans was that of condemning the criminal to fight with wild beasts. Impalement, by thrusting a sharp stake through

the body lengthwise, was one of Nero's cruelties, and is referred to by Juvenal. It is said to have been practised in the Balkan Peninsula so recently as 1876. Under Charles V. impalement was effected by driving a pointed stake through the heart while the criminal in open grave was being covered with earth. Other barbarous modes of execution were pouring melted lead on the criminal; sawing him asunder, a mode practised by the Jews against the conquered in Palestine; starvation in dungeons; pressing to death; breaking on the wheel; tearing to death with red-hot pincers. Boiling alive was occasionally practised on the Continent; and in England in Henry VIII.'s time poisoning was punishable by boiling to death, and 'it seems,' says Sir James Stephen, 'that three or four persons were so boiled.' In 1532 sentence of boiling alive was put in execution against a miscreant who attempted to poison Fisher, Bishop of Rochester, and actually poisoned some of his household. The act under which that sentence was carried out was repealed by 1 Edward VI. Drowning a parricide in a sack, in which were also a dog, cock, viper, and ape, was a Roman punishment, initiated in the middle ages, when quartering alive, tearing to pieces by horses, and disembowelling were likewise punishments known on the Continent. Among the severer forms of military execution were hunting and spearing the condemned to death by his fellow-soldiers, practised in Germany in the time of the Lanzknechts of the end of the 15th and during the 16th century; making him run the gantlet of rods till dead; flogging him to death with the knout. These last two modes of execution were practised in Russia till into the 19th century.

English law has in practice, according to Sir J. Stephen, been in a marked manner distinguished from the practice of the Continent by its aversion to execution by torture. The usual mode of execution in England has been for many centuries, and still is, hanging, though in early times decapitation was also known. Treason, however, was punished in the case of men by hanging, drawing (anciently dragging at the tail of a horse), and quartering; in the case of women by burning. A woman was burned alive for treason at Tyburn in 1685. Heresy was also punished by burning. In 1283 David, the last native Prince of Wales, was for treason sentenced to be hanged, drawn, and quartered, and to have his bowels burned. Pressing to death, or the *peine forte et dure*, is said to have been practised as late as 1741 at the Cambridge assizes. Burning continued till 1790 to be the punishment inflicted on women for treason, high or petty; at Ipswich a woman was burned in 1783 for murdering her husband. In practice, however, women were strangled before being burned. A woman was burned for witchcraft at Dornoch in Sutherland in 1722. By 25 Geo. II. any person convicted of murder was to be executed on the next day but one after sentence, but if sentenced on a Friday he was to be hanged the following Monday. In the interval he was to be fed on bread and water, and his body after death was to be either dissected or hung in chains. By laws passed in 1832-34 the bodies of murderers were no longer to be anatomised or hung in chains, but to be buried in the precincts of the prison in which they were last confined before execution. This regulation, repeated in 24 and 25 Vict., is now in force. On 21st February 1803 Edward M. Despard (q.v.) was drawn on a hurdle, hanged, and decapitated; and on 1st May 1820 Thistlewood and four of his fellow-conspirators were likewise hanged and decapitated. In this case—the last

execution for treason in England—the head was cut off with an amputating knife by a masked executioner, who then thrice held it up by the hair to three different points of the compass, with the words, 'This is the head of Arthur Thistlewood, a traitor.' The mode of execution now obtaining in England, North America, and Austria is hanging; in Spain, Garroting (q.v.); in France, decapitation by the guillotine; in Germany, decapitation—by the axe in Prussia, elsewhere by the guillotine. In New York state it was enacted that after 1st January 1889 executions should be by electricity, a mode calculated to effect instantaneous death. Lynching (q.v.) sometimes takes the place of judicial execution in America. The Bowstring (q.v.) was an old Turkish institution; and the Hari-Kari (q.v.) was peculiar to old Japan. Shooting is the military form of execution. In India, during and after the mutiny of 1857–58, some of the rebels were blown from the mouth of cannons. Till 1868 executions in the United Kingdom were performed publicly, in London for the most part at Tyburn till 1783. At Edinburgh the place of execution was chiefly in the Grassmarket till 1784, when it was transferred to a platform at the west end of the Tolbooth, a building removed in 1817. The gallows at Tyburn was a permanent erection on three posts, 'Tyburn's triple tree,' and wooden galleries near it accommodated the crowds of spectators. The scandalous scenes, however, attending the procession of the criminal from Newgate to Tyburn caused the place of execution to be changed in 1783 to the area in front of Newgate prison, where on the 3d December 1783 ten were executed.

In 1868 an act was passed prohibiting public execution, and directing that all executions proceed inside the walls of the prison in presence of the sheriff, gaoler, chaplain, and surgeon of the prison, and such other officers of the prison as the sheriff requires or allows. The Act of 1868 further orders that execution take place at 8 A.M. on the first Monday after the intervention of three Sundays from the day on which sentence is passed. A black flag has to be hoisted at the moment of execution conspicuously above the prison, and remain displayed for an hour, while the bell of the prison or parish church tolls for fifteen minutes before and fifteen minutes after the execution. Till 1783 the mode of execution was by drawing away the cart from under the prisoner after the rope had been fastened round his neck. From 1783 the prisoner was placed not on a cart but on a platform, which on the withdrawal of a bolt suddenly fell from under him. In 1874 this method was improved upon by a plan whereby the length of the rope is proportioned to the weight of the body, so that the momentum of the fall suffices to rupture the ligatures of the spine, and thus cause instant death. Execution in England must in all cases be performed by the sheriff, or, as is invariably the practice, by his deputy called the executioner. In royal burghs in Scotland, the office is imposed on the civic magistracy, one of whom attends the execution, similarly as does the sheriff in England.

In several German states the office of headsman is said to have been hereditary, and in *Coriolanus* (act ii. scene 1) Menenius speaks of 'hereditary hangmen.' The last headsman of the Tower of London died in 1861. The office had grown to be a mere sinecure. In some parts of England the office was annexed to other posts; for instance, in the time of Henry II. and Henry III. the porter of the city of Canterbury was executioner for the county of Kent, and in receipt on account of that office of an allowance of 20 shillings per annum from the sheriff. Derrick was public executioner in the first part of the 17th century, and gave his

name to a kind of craze; after him came Gregory Brandon, whose son, Richard Brandon, executed Strafford, Laud, and Charles I. John Ketch, public hangman from 1663 till 1686, executed William Lord Russell and the Duke of Monmouth, and bequeathed his name ('Jack Ketch') as a nickname to his successors in office for nearly two centuries. The family of Sanson for many generations gave Paris her executioners, the name 'M. de Paris' being first playfully given to the elegant and handsome Charles Henri Sanson, who in his old age executed Louis XVI. In recent times, Calcraft, employed as executioner down till 1874, was paid by the corporation of London £1, 1s. per week as a retaining fee, and an extra £1, 1s. for each execution. He had, besides, from the county of Surrey £3, 5s. annual retaining fee, and £1, 1s. for each execution, and £10 for an execution in the country. Calcraft was succeeded in 1874 by Marwood, who, in turn, in 1883, was succeeded by Berry, who, in the six years following his appointment, was engaged for over 200 executions, and carried over 100 sentences into effect.

(1868); *Hanging not Punishment enough for Murderers, &c.* (1701); a collection of broadsides, containing an account of murders and executions (1794–1800; and another collection, 1830–55?); *Memoirs of the Sansons*, edited by Henri Sanson, late executioner of the Court of Justice of Paris (Eng. trans. 2 vols. 1875); *The Punishment and Prevention of Crime*, by Sir E. F. Ducane, in 'English Citizen' series (1885). See also the articles DROWNING, GUILLOTINE, MAIDEN, NEWGATE, PARRICIDE, PEINE FORTE ET DURE, TYBURN, and WHEEL (BREAKING ON THE).

**Execution of Deed.** See DEED.

**Executive.** See GOVERNMENT.

**Executor**, in England, the person to whom the execution of a last will and testament of personal estate is by testamentary appointment confided. The appointing by will of an executor, without giving any legacy or appointing anything to be done by him, is sufficient to make a will. The appointment of an executor can only be by a will, the person who takes charge of the estate of an intestate being called an Administrator (q.v.). The appointment may be either express or constructive—i.e. gathered from the general terms of the will. An early duty of an executor is to take Probate (q.v.) of the will. He derives his title solely from the will; the estate vests in him from the death of the testator, at which time his responsibility begins, and from which time he may enter upon all the duties of managing the estate. But his position will not be recognised as snitor in any court until he has taken probate. The whole personal estate vests in the executor, and, if the testator has made no disposition of the residue, it devolves, as trustee for the next of kin, upon the executor, unless it appears from the will or any codicil thereto that the executor was intended to take the residue beneficially. By 21 Henry VIII. chap. 5, an executor is bound to prepare an inventory of the personal estate. This, if required, must be produced. An executor may raise actions in respect to the estate in his charge; and generally it may be said that his powers, duties, and liabilities are commensurate with those of the deceased, except in regard to contracts and wrongs of a merely personal nature. He may enter the house of the deceased to remove the personal property. The first claims to be discharged are those of the funeral and the expenses of probate. He must then pay the debts; and he is responsible for paying them in due order, so that those having a legal preference shall first be

discharged. An executor is not bound to accept the office; but, if he administers, he cannot then renounce the executorship without cause. On the death of an executor, the office passes, as a general rule, to his executor. See Sir E. V. Williams's *Law of Executors and Administrators* (8th ed. 2 vols. 1879), or the shorter treatise of Walker and Elgood (1883).

An executor to a will in Scotland is called a testamentary executor, to distinguish him from the next of kin, who are styled executors. The term executor is given to all who manage the estate of a deceased, whether appointed by will or by authority of the court. The former are called executors nominate; the latter, executors dative. All executors must, before entering upon their duties, obtain *confirmation* from the Commissary Court. This is equivalent to probate in England. But in Scotland no right vests in the executor until after confirmation, except a title to sue, being exactly the reverse of the English rule. An executor acting without confirmation is called a *Vitiosus Intromitter* (see INTROMISSION). Executors must, on entering upon their office, exhibit a full inventory of the whole movable estate of the deceased. An executor is only liable to the extent of the inventory. He is not bound to pay interest on the funds in his hands unless they bore interest before confirmation, or unless he is guilty of undue delay in administering the estate. He is not bound to pay the debts for six months after the death of the deceased. But, as in England, the expenses of the funeral and confirmation are entitled to immediate payment. Servants' wages and a year's house-rent have also a preferable claim. An executor is entitled to claim one-third of the *Deud's Part* (q.v.), after deducting debts. But, should he receive a legacy, he is bound to impute that towards part payment of his claim.

In the United States, the rights and duties of an executor are analogous to those defined by English law; in this, as in other matters relating to property, each state has its own laws. See Stimson, *American Statute Law*; Schouler, *Treatise on Law of Executors and Administrators* (Boston, 1883).

**Executory**, in English law, is a term applied to contracts, &c. which are not executed—i.e. not completed with the forms required to make them legally operative. An executory limitation of property is one which gives an interest to come into existence at a future time or on the happening of an event. An executory trust directs trustees to make a proper conveyance in favour of the person beneficially entitled. Executory devises and other limitations form an important branch of the law of real property. In American law, the term executory is used as in England; executory gifts of property are subject to rules against Perpetuities (q.v.), similar to the rules which prevail in England.

**Exegesis**, a Greek term meaning the exposition or interpretation of any writing, but almost exclusively used of the interpretation of the Holy Scriptures. The term *Hermeneutics* is frequently applied to the science of the interpretation of the Bible, and it is usual to distinguish it from exegesis as the interpretation proper or *discovery* of the true meaning of the text, while the latter is more strictly the *exposition* of the meaning so discovered and its practical doctrinal and moral applications. But it may be said that the term exegesis is now in pretty general use as applied at once to the science and the art of the elucidation of Scripture. It includes both the study of the text or form in which the scriptural revelation has reached us and also the scope and doctrinal bearings of that text and the

conclusions that may reasonably be deduced from it. The materials for the critical study of the Old Testament are scanty as compared with the New, hence the difficulty of attaining to certain conclusions is correspondingly greater. Critical materials are mainly of three kinds: MSS., versions, and quotations. Of these the New Testament scholar has enough, but the student of the Old Testament is worse than slenderly equipped in all. For the present Hebrew consonantal text is hardly earlier than the 2d century of our era, the vowel signs being some centuries later; while, as for the versions, the Syriac, the Targum or Chaldee, and the Vulgate are substantially mere reproductions of the Hebrew text we possess, the difficulty in the case of the Septuagint being increased by the undoubted corruptness of its own text, as well as by the fact that it is itself a translation into Greek of an earlier Hebrew version now unknown to us. Nor can we supplement our knowledge to any extent from the source of early quotations, as the Fathers, with the exception of Jerome and to some extent of Origen, were ignorant of Hebrew, and, besides, were hopelessly given to quoting Scripture very loosely and inexactly.

Thus the task of the exegete is a labour of great and complicated difficulty, and he must needs be a scholar, competently equipped for grammatical and philological inquiries into the signification of words, the force and significance of idioms, the modification of the sense by the context and the comparison of parallel passages, no less than into the character of the writer and the persons he addressed, of the circumstances in which he wrote, and the immediate object to which his work was directed. To these linguistic and literary qualifications he must add adequate knowledge of contemporary external history, but above all he must have something of that spiritual sympathetic insight by which he can project his own imagination into the mind and feelings of an earlier age. Without some measure of this *inwardness* no scholar, however brilliant, can be a great exegete; but, when it is superinduced upon extensive and exact learning, we have an exegete of the first order—a Chrysostom, a Calvin, a Bengel, a De Wette, a Meyer, or an Ewald. Thus Schleiermacher's saying, that 'in a certain sense the interpreter has to induce more than the author introduced,' is true; for the exegete, exercising the synthetic as well as merely analytic faculty, reconstructs for himself the mental attitude of the writer in order to deduce much that influenced the latter half-unconsciously in his composition.

All exegesis of Scripture, however closely it follows the ordinary methods of literary and historical criticism, depends greatly upon the views entertained as to the nature and degree of inspiration, and the share of the conscious human element in the progressive revelation. The old theory of *dictation* or verbal inspiration is no longer held by any intelligent scholar, and it is the peculiar merit of our 19th-century exegetes to have been the first to establish a satisfactory critical *modus vivendi*—by their insisting upon the human element in the Scriptures without ceasing to uphold their divine authority.

It is hardly necessary to point out how absurd is the assumption of some sects that a scholarly interpretation of Scripture is superfluous to the Christian, whose sole aim is the shortest cut to salvation. For, not to speak of the inherent difficulty of Scripture itself as a series of compositions extending over hundreds of years, and treating intimately of many things long forgotten, and that often in figurative and symbolical phraseology unfamiliar to a modern ear, has not God in his providence seen fit to give his revelation in

languages which demand the exegetical praxis of translation? And do not the immense divergencies of honest opinion about the interpretation of Scripture give the individual such a wholesome distrust in the infallibility of his own opinion that he feels the need of every possible support that he can gain from scholarship to buttress it? For the sincerity of a conviction is no proof of its absolute truth, since honest men have been sincerely convinced of the truth of opinions the most opposite. At the same time it is true that the things of faith essential to salvation are perfectly plain to the reason and judgment of every man, and that Scripture is of necessity itself intelligible and sufficient, if studied with diligence and a candid mind. The precious right of private judgment is perfectly consistent with the need for a scientific exegesis, the interests involved in the correctness of the interpretation being so momentous.

The fundamental distinction between Roman Catholics and Protestants depends upon the extent to which the private judgment of the individual is to be controlled by external considerations, such as the authoritative interpretations of the Fathers, and the dogmatic definitions of councils and popes. The former, of course, do not consider the Scripture as containing the whole of God's revelation, and therefore, just as Protestants admit that one passage of Scripture may be modified by another, so they believe that the scriptural revelation itself may be modified by other revelations of God conveyed to us through other mediums, as by that of tradition. Unfortunately, tradition is far from consistent, and is not always even intelligent; and the traditionalist frequently finds himself under the necessity of bowing down his judgment to the exegetical conclusions of an age devoid of real scholarship, and slavishly subject to an allegorical or other fantastic method of interpretation.

The Jewish exegesis of the Old Testament is seen in the voluminous Talmudical writings, the *Mishna*, giving simplifications and explanations of the law, and the *Gemara*, giving further explanations of earlier explanations, the latter itself existing in the two forms of the *Jerusalem Talmud* and the *Babylonian Talmud*. The earliest Jewish Scripture interpretation was the *Midrash* ('study'), divided into legal and homiletical exposition. The legal, *Halacha* ('rule by which to walk'), was mostly confined to an amplification of points not explicitly set forth in the Pentateuch, from which it deduced the collection of precepts designated *Halachoth*; while the homiletical, *Hagada* ('opinion'), discussed the whole Old Testament, and aimed at applying it to ethical and social as well as to religious questions. It became so popular that it was styled distinctively the *Midrash*, and, with much practical value, contained many fantastic interpretations, the result of a distinction between the natural and the derivative or allegorical sense. Side by side with this, however, there grew up during the middle ages a more rational exegesis, which gave really sound results in the hands of such enlightened rabbis as Jarehi, Rashi, Kimchi, Maimonides, and Abarbanel.

The hebraeities of the *Hellenistic* Jews had sought by thoroughgoing allegorical interpretation to make an arbitrary reconciliation between the traditions of Hebraism and the results of Greek philosophy. The greatest master of this perilous art was Philo, who formulated definitely the two-fold teaching in the Pentateuch—the verbal sense for the illiterate, the figurative for those gifted with the insight to see it. The allegorical system of interpretation was adopted by the Alexandrian school, and carried far by Clement and the great Origen; yet the latter also established a basis for sound grammatical exegesis by his separation

between the literal, the moral, and the mystical senses. The same influences, although to a less extent, show themselves in such western teachers as Hippolytus, Hilary, Ambrose, and Augustine; but, in marked contrast, the school of Antioch, as represented by Diodorus of Tarsus, Theodore of Mopsnestia, Chrysostom, and Theodoret, aimed rather at a grammatical and historical criticism, that at its worst degenerated into a bald and unspiritual interpretation. Basil of Caesarea, Gregory Nazianzen, and Gregory of Nyssa show a similar preference for the objective reading of Scripture, as also the learned Jerome, who advocated the grammatical and historical sense as the fundamental, with the figurative interpretation where necessary, in opposition to the allegorical. Meantime, in the Western Church, theologians, in the face of the divergencies of heresies each based upon its own reading of Scripture—and that mostly always allegorical—had been finding the necessity of an authoritative exegesis of Scripture as an ultimate standard of appeal. Already, under this necessity, in Irenaeus and Tertullian we see the growth of a simpler and more rational spiritualising of Scripture as a reaction against excessive abuse of arbitrary and fanciful allegorising; together with that increasing respect for authoritative explanation of the sense. This finally culminated in the conclusion of the Council of Trent, that the sole right to interpretation was inherent within the church herself, and in the assertion by the Vatican Council of the personal infallibility of the pontiff. The *Communitorium* of Vincentius of Lerins established the doctrinal supremacy of Scripture, but, from its inherent difficulty and the vagaries of individual interpretation, maintained the necessity of the tradition of the church to supplement and expound it. His famous '*Quod ubique, quod semper, quod ab omnibus creditum est*' may still be accepted as the axiom that dominates all Roman Catholic exegesis. Independent interpretation went gradually out of use, and was supplanted by the well-known *Catenae*, consisting of expositions of books of Scripture strung together from the writings of such Church Fathers as Origen, Chrysostom, Jerome, and Augustine. These were themselves prepared by such divines as Procopius of Gaza, Cassiodorus, Hrabanus Maurus, Sedulius, Theophylact, and Aquinas. The middle ages gave its intellect to abstract theological speculation—in exegesis it bound itself voluntarily in the shackles of tradition. The *Postilla*, or brief commentaries, of Nicolaus de Lyra was a symptom of a reaction towards the obvious and objective that soon showed itself also on the philological side in the Humanists, Laurentius Valla, Reuchlin, and Erasmus, and in the bolder spiritual applications of the Reformers. Their intense religious experiences supplied the real inwardness that was lacking to the Humanists, and accordingly in Luther, Melancthon, Beza, Bucer, Ecolampadius, Zwingli, and Calvin we find a series of great exegetes whose influence is even now more visible in the recent biblical criticism of Germany than it was at the time of the Reformation itself. Among the greatest of their more immediate successors were Grotius, Calovius, Calixtus, and Cocceius. Little further progress, however, was made till about the middle of the 18th century, as scriptural exegesis was mostly allowed to degenerate into mere edification, which it was not given to every scholar to harmonise so happily with real science as Bengel did in his famous *Gnomon Novi Testamenti* (1742). The revival of a real exegesis is due mainly to Ernesti and Semler, whose inspiring impulse created a school of scholars who in a single generation contributed more to a sound

knowledge of the Scriptures than all the theologians of sixteen centuries. Such were, in the field of Hebrew scholarship, Gesenius, Ewald, Olshausen, and Böttcher; in that of Greek, Winer, Buttmann, Lachmann, and Griesbach; and on the purely philosophical and theological side, Herder, Baur, Rothe, Hofmann, Lücke, and Schleiermacher. Since these a continuous chain of illustrious and more or less orthodox scholars have laboured at the direct elucidation of Scripture on sound scientific lines, of whom it may here suffice merely to mention the names of De Wette, Bleek, Hitzig, Hupfeld, Hengstenberg, Keil, Oehler, Knobel, Kalisch, Rosenmüller, Dillmann, Meyer, Lange, Tischendorf, Lagarde, Delitzsch, Godet, Holtzmann, Ellicott, Lightfoot, Perowne, Scrivener, Westcott, and Cheyne. At the same time the horizons of our knowledge of ancient Egypt and Assyria have been vastly widened by the labours of scholars like Lenormant, Maspero, Rawlinson, Schrader, and Sayce, who have cast a flood of light and confirmation upon the ancient history contained in the Bible, which has also been elucidated more immediately from the history of the Jews themselves, by the work of Ewald, Stade, Gratz, Stanley, Kuenen, Wellhausen, and Renan. The study of the New Testament history and of the life of our Lord—so characteristic a feature of the more modern theology—has contributed no less to our knowledge of the scope and contents of the New Testament books, through the work of Strauss, Renan, Lange, Hase, Keim, Weissaker, Lechler, Hausrath, Schürer, and Weiss. No less valuable side-light for exegesis proper has been afforded by works specially devoted to the history of theological dogma and its progressive development, such as those of Dorner, Martensen, Nitzsch, Hagenbach, Ritschl, Pfleiderer, and Harnack.

See the articles BIBLE, CODEX, GOSPELS, and SEPTUAGINT; also the separate articles on the various books included in the canon of Holy Scripture, as well as upon the great exegotes themselves.

**Exelmaus**, REMY JOSEPH ISIDORE, COMTE, a distinguished French general, was born at Bar-loduc, 13th November 1775. Entering the army in 1791, he served with distinction in the campaign of Naples under Championnet, was made general of brigade after Eylau, and followed Murat to Spain, where he was taken prisoner and sent to England. For his conduct in the disastrous Russian campaign Napoleon created him a general of division. Exelmaus seems to have been equally esteemed under every successive government. On the fall of Napoleon, he was for some time banished from France, but was permitted to return in 1823. In 1831 Louis-Philippe restored his titles and rank. Louis Napoleon named him Grand Chancellor of the Legion of Honour, and in 1851 raised him to the dignity of Marshal. On the 21st July 1852 Exelmaus had a bad fall from his horse, from the effects of which he expired on the following night.

**Exemplar.** See FABLE.

**Exequatur.** See CONSUL (MERCANTILE).

**Exeter**, the capital of Devonshire, 171 miles by rail WSW. of London, and 75 SW. of Bristol. Dominated by higher hills, it is built on the summit and slopes of a flat ridge, rising 150 feet from the left bank of the Exe; and, having been modernised chiefly in its suburbs, it is a pleasant antique city

—‘as good a specimen of an English county town, at once prosperous in business, and with a quiet air of aristocratic distinction, as can be found within the four seas’ (Escott’s *England*). The quaint old High and Fore Streets, crossed by North and South Streets, still follow the line of the Ickneld Way; and the walls in great part remain, though their four gateways were demolished between 1769 and 1819, and though Rougemont Castle (1068) was almost all swept away in 1774, to make room for an ugly assize-hall. In 932 Athelstan founded here a Benedictine monastery, and hither in 1050 Edward the Confessor translated the western

Exeter Cathedral: West Front.

bishopric from Crediton; but St Peter's Cathedral was not begun till sixty-two years afterwards. Measuring 408 feet by 76 (or 140 across the transepts), and 66 feet high, it is a long, low edifice, with massive transeptal towers—a feature imitated at Ottery St Mary, but otherwise unique. These towers, 140 feet high, are the original Norman ones, but the rest of the pile, rebuilt between 1280 and 1369, is mainly in the purest Geometrical Decorated. The most striking characteristics of the whole are its perfect bilateral symmetry and the grand unbroken line of vaulting. Special features are the exterior western screen (*circa* 1388), adorned with sixty-seven statues of saints and princes; the beautiful choir-screen (1324), surmounted by the fine organ (1665); the minstrels' gallery (1353); the misericords, sedilia, and bishop's throne; the modern reredos, stall-work, and pulpit; a clock, dating from 1317 or earlier; the Great Peter bell, brought from Llandaff in 1482, recast in 1616, and weighing 12,500 lb.; and the chapter-house (1420-78), containing 8000 MSS. and early books. In 1870-77 the cathedral was restored by Sir G. G. Scott at a cost of £40,000; in 1889 the cloisters and library. The picturesque guild-hall (1464) has a cinque-cento façade (1593); of modern buildings, the most noteworthy are the Devon and Exeter Hospital (1743), the Lunatic Asylum (1865), and the Albert Memorial Museum (1868). The chief public walk is Northernhay. A ship-canal (1563-1827) extends 5 miles to the tideway at Topsham; and Exeter has large nurseries and manufactures of gloves, agricultural implements, &c., besides being the chief mart of 'Honiton' lace. But its woollen trade, once second only to that of Leeds,

is a thing of the past; and as a seat of commerce and industry it has been outstripped by many a younger competitor. The 'ever loyal city' got its earliest charter from Henry II. some time prior to 1162; in 1537 was made a county of itself; and returned two members from about 1300 till 1885, when their number was cut down to one. Pop. (1851) 40,688; (1881) 47,154, of whom 37,655 were within the municipal borough.

The Celtic *Caerwise*, the Roman *Isca Damnoniorum*, and in 876 the *Eccanceaster* of the West Saxons, who till 926 shared it with the Britons, Exeter, in Professor Freeman's words, 'is the one great city of the Roman and the Briton which did not pass into English hands till the strife of races had ceased to be a strife of creeds, till English conquest had come to mean simply conquest, and no longer meant havoc and extermination.' To Mr Freeman's pages reference must be made for its capture by the Danes (876 and 1003), by William the Conqueror (1068), and by Stephen (1136); for its siege by the Yorkists (1470), by Perkin Warbeck (1497), and by the Catholic rebels (1549); for its surrender to Prince Maurice (1642) and to Fairfax (1646); and for the entry of William of Orange (1688). Whereto must be added the tragic burning of the new theatre (5th September 1837), with a loss of 188 lives. Among the sixty bishops have been Leofric (1050-72), Bartholomew (1161-84), Stapledon (1308-26), Grandison (1327-69), Miles Coverdale (1551-53), Joseph Hall (1627-41), Seth Ward (1662-67), Trelawney (1689-1707), Phillpotts (1831-68), and Temple (1869-83). Natives were Archbishop Baldwin, Cardinal Langton (doubtfully), John Vowel or Hoker, the historian of Exeter (1525-1601), the Judicious Hooker, Sir Thomas Bodley, and Henrietta, Duchess of Orleans.

See Archdeacon P. Freeman's *Architectural History of Exeter Cathedral* (1873), and Professor E. Freeman's *Exeter* ('Fictitious Towns' series, 1887).

**Exeter, PEERAGE OF.** See BURGHLEY.

**Exeter Hall**, a large proprietary building, on the north side of the Strand, London, was completed in 1831, and can contain upwards of 5000 persons. It is let chiefly for religious assemblies, and is in great request during the 'May Meetings' of the several religious societies. It has also been the scene of many great musical fêtes. In 1880 it was purchased for £25,000 for the Young Men's Christian Association.

**Exhibitions.** The earlier beginnings of Industrial Exhibitions, like all great movements, are not particularly easy to define. The first exhibition of anything like national importance, however, seems to have been the one originated by the Marquis d'Avèze at Paris, 1798, though previous to this a show of agricultural and other machinery had been held by the Society of Arts in London (1756), and another exhibition had been given at Prague in 1791. A second exhibition of greatly improved kind was opened at Paris in 1802; a third in 1805; and hence arose the custom of holding such displays triennially, continued with slight interruption for half a century. It should be mentioned that the specimens exhibited on these occasions were essentially of French production, and care was taken to exclude any article of foreign character. The impetus given to the movement by the Paris displays was felt over Europe, and even reached the United States. Between the years 1820 and 1850 exhibitions were held at Vienna, Berlin, Brussels, St Petersburg, Stockholm, Moscow, Lisbon, Madrid, New York, Philadelphia, and numerous other towns. Nor did the United Kingdom escape the infection, though here the promoters of such undertakings had to struggle against much apathy and even opposition.

To Ireland belongs the credit of the first display of noticeable merit. This was the Exhibition of Irish Industries, held by the Royal Dublin Society at their rooms in 1829, and the association continued the practice triennially for several years. The Society of Arts in London also held a number of exhibitions illustrative of the manufactures, commerce, and agriculture of the country, and the Cornwall Polytechnic Society energetically laboured in a similar direction by holding periodical exhibitions to illustrate the mineral wealth of that county, and the mechanical appliances necessary for mining. From this may be said to have originated the happy idea of holding in various large towns exhibitions descriptive of the industrial work carried on in the locality. Manchester led the way with a display of everything concerned in the manufacture of cotton; Liverpool followed with an exhibition of the raw produce brought to that seaport, and the shipbuilding that rendered such trade possible; Leeds held an exhibition of the material and processes involved in the flax and woollen trades; and Birmingham (1849) fairly surpassed them all with an excellently arranged show of the numerous useful and ornamental forms into which metals can be wrought. The Birmingham Exhibition may be said to have had an important influence in bringing about the first great exhibition of 1851.

For some time past the English government had been urged without success to organise an exhibition in London of a really national character, illustrating the arts of Great Britain and Ireland. In the spring months of 1849 the Society of Arts, being greatly influenced in the matter by Prince Albert, sketched the outline of a great exhibition of the industries of all nations, and proposed that such exhibition should be held at London in 1851. In July the prince in the name of the society applied to the government for the appointment of a Royal Commission to organise and manage such an exhibition. As a result of the agitation then set on foot, the Commission was appointed early in 1850, with the prince at its head; and the exhibition was opened by the Queen in Hyde Park, May 1, 1851. It was held in a vast structure of iron and glass, called the Crystal Palace (now located at Sydenham), and planned by Sir Joseph Paxton (q.v.). The building was 1851 feet long by 408 wide, with an additional width of 43 feet for half that length; the highest portion was a centre transept 108 feet high; the area covered was 19 acres, equal to seven times that of St Paul's. The exhibitors numbered nearly 15,000, about equally divided between British and foreign contributors. The cost of the structure was £170,000 (for use and waste, not for absolute ownership), which in addition to the other expenses down to the close of the exhibition made a total outlay of £292,795. The entire number of visitors was 6,039,195, averaging 41,938 per day. The total receipts from admission and other sources amounted to £505,107, leaving a surplus of £200,000.

The next exhibition of any importance was the one of art and industries held in a specially erected structure at Dublin, 1853, mainly through the enterprise and munificence of Mr Dargan. It resulted in a very heavy pecuniary loss, as did the New York International Exhibition of the same year, and the Paris Exhibition of 1855. Between 1853 and 1857 exhibitions of more or less interest and practical value were opened at New Brunswick, Madras, Munich, Edinburgh, and Manchester.

The second great international exhibition of 1862 was held in a building at South Kensington, occupying an area of about 24 acres. In its main building it was composed of massive brickwork, but the annexes and two cupolas of vast magnitude were chiefly of glass, iron, and wood. The total area of

covered space was nearly 1,300,000 feet, including corridors, staircases, &c. About 700,000 square feet were ground-floor space, the remainder galleries. So excellently were the arrangements carried out that the exhibitors had 1,032,352 square feet of horizontal flooring and 284,670 square feet of vertical wall-space. About one-half was allotted to the United Kingdom and its colonies, the other half to foreign countries. The total number of exhibitors was 28,653, of whom 26,348 were in one or other of thirty-six industrial classes, the remainder in one or other of four fine art classes. There were 3370 paintings in oil and water colours, 1275 etchings and engravings, 983 architectural drawings, &c., and 901 pieces of sculpture. The exhibition was open 171 days, nearly a month longer than that of 1851. The visitors numbered in all 6,211,103 persons, but though the number was greater than in 1851 the average per day was less. The receipts from all sources (admission at the doors, season tickets, refreshment contracting, &c.) amounted to the grand total of £448,632, but the cost of the building was so great (£320,000, virtually for six months' use only) that the receipts did not cover the outlay, and a deficit of about £10,000 was the result.

Passing over exhibitions held at Constantinople (1863) and Bayonne (1864), we next come to the Dublin Exhibition of 1865, produced under the auspices of a joint-stock company, which proved a great failure. During the few years that followed exhibitions of more or less national character were held at Cologne (1865), Oporto (1865), Stockholm (1866), Melbourne (1866), and Agra (1867). In 1867 came the Paris Exhibition, which in its general arrangement and magnitude of conception surpassed anything that had yet taken place. This was a really wonderful undertaking. The building was a vast oval, 1550 feet by 1250, with a series of twelve concentric galleries running round it, and a small garden in the centre. In each gallery a separate branch of science and art was illustrated, and the entire oval was divided into sections, one of which was devoted to each country. The oval covered 11 acres, and the complete exhibition, counting the various annexes and outside grounds, close upon 100. The number of exhibitors was 50,226, and the total expense £800,000, half of which was defrayed by the public attendance, half by the imperial government and the Paris municipality; visitors, 10,200,000. Britain, it may be mentioned, did not figure very favourably in this exhibition—probably by reason of the want of technical education—whereas Germany, France, and Belgium showed a marked advance. Following this, exhibitions were held at Havre (1868), Amsterdam (1869), Sydney (1870), Milan, Naples, Jersey, and Peru (1871), Dublin, Copenhagen, Lyons, and Moscow (1872), and a very fine one—the greatest in fact since that of Paris—at Vienna in 1873. The last exhibition, however, was most unfortunate, suffering not only from very bad management, but from a variety of detrimental causes over which the promoters had no control, and proved in the end a huge financial failure.

In 1871 the first of a series of annual London International Exhibitions was opened. The movement, however, never became popular, and after gradually declining in favour for four years was finally relinquished in 1874. The next most important display after Vienna was the Philadelphia Centennial Exhibition of 1876, held in commemoration of the hundredth anniversary of American Independence. The main building, in the form of a parallelogram, covered a floor-space of about 20 acres; its length was 1880 feet, and width 464. One centre and two side avenues ran along the inside of the edifice, the former being 1832 feet

long by 120 feet wide—the longest avenue of that width ever known in an exhibition structure. The total area of floor-space in the various buildings amounted to about 50 acres; of this more than 1,000,000 square feet were allotted to the United States; 200,000 to Great Britain and its colonies; about 100,000 to France and French dependencies; and over 60,000 to Germany. The number of exhibitors fell below those of the preceding exhibitions at Paris and Vienna—in all about 40,000. The building was open to the public on 169 days, and the total attendance of visitors was 9,910,966; receipts, \$4,800,000—a sum much below the expenditure. The Paris International Exhibition of 1878 again made an advance in magnificence and size upon all previous displays, and as a collection of fine art and literature was especially notable. The total area covered by the various buildings was about 80 acres, and the exhibitors numbered as many as 80,000. The visitors were 16,032,725, and the gross receipts £506,149. Since the Paris Exhibition the chief displays of this kind have been those held at Berlin and Sydney (1879), Melbourne (1880), Berlin, Moscow, and Buenos Ayres (1882), Louisville, U.S., Caracas, and Amsterdam (1883), Calcutta and New Orleans (1884), Antwerp (1885), Edinburgh and Liverpool (1886), Manchester (1887), Melbourne, Glasgow, and Brussels (1888), Edinburgh (1890), Frankfurt (electrical, 1891), and Chicago (1892). At London have also been held the Electrical (1882), International Fisheries (1883), Health (1884), Inventions (1885), Colonial (1886), American (1887), Italian, Irish, and Anglo-Danish (1888), Spanish (1889), Military (1890), German and Naval (1891), and Electrical (1892) Exhibitions.

On May 5, 1889, the Universal Exhibition of Paris, excelling all its predecessors in point of magnitude and comprehensiveness, was opened. With the included grounds it occupied an area of no less than 173 acres. The Eiffel Tower (q.v.) was one of the principal attractions of the exhibition. As a marvel of constructive skill it was rivalled by the Machinery Palace, which had a span of 377 feet, and was without pillars or other similar support. On the opening day of the exhibition the visitors, exclusive of official sightseers and *invités*, numbered 112,294, and for the first week 350,215. Minor exhibitions in 1889 were the Exhibition of Arts and Industries, Hamburg, the Accident Prevention Exhibition, Berlin, and the Goldsmiths' Exhibition, Vienna.

**Ex-Libris.** See BOOKPLATES.

**Exmoor Forest**, in the west of Somersetshire and north-east of Devon, is a wild, mostly uncultivated waste, consisting of long ranges of steep hills and lonely valleys, and bordered by deep wooded glens. The hills rise in Dunkery Beacon to 1707 feet, in Chapman Barrow to 1540, and in Span Head to 1610. The 'forest' proper is about 25 miles in area, but with the adjacent commons Exmoor extends over 100. The rocks belong to the Devonian series, mainly slates and sandstones. Hence the outlines are less bold and rugged, and the general aspect far less stern and desolate than that of Dartmoor, ribbed and spread with granite. Though 'improvements' were attempted in 1818, and many trees planted by Mr J. Knight, who had purchased the forest from the crown, Exmoor is still in the main covered with grass (in some parts short and sweet, in others rank and sedgy), bracken, and heather, with dangerous bogs near the hill-tops. Where it ranges down to the coast near Lynton, the scenery is very bold and picturesque. The Exe, Barle, Mole, and the two Lys are the chief streams rising here. Gold has been found in Northmolton parish, and

copper-mines have been worked there from time to time. There is a native breed of very small ponies, known as Exmoor ponies, stout and hardy, as well as a local breed of horned sheep of high quality. The most notable feature of the fauna of Exmoor is, however, that it is the only place in England where the red deer still run wild. A few years since the extinction of this noble race seemed imminent, but recently they have been preserved, and are now becoming numerous. Stag-hounds have been kept here and stag-hunting followed since at least 1398. Exmoor is the chief scene in Blackmore's *Lorna Doone*, which is based largely on local traditions, and which abounds with admirable descriptions of its most characteristic scenery. See also H. B. Hall's *Exmoor* (1849), and C. P. Collyns's *Chase of the Wild Red Deer* (1862).

**Exmouth**, a Devonshire watering-place, at the east side of the mouth of the Exe, 11 miles by rail SSE. of Exeter. A sheltered spot, with fine climate, good beach, and beautiful views, it had dwindled from a considerable seaport to a poor fishing-village, when, about the beginning of the 18th century, it rose into repute as a seaside resort; and now it has terraces, hotels, baths, promenades, and pleasure-grounds along the seashore, and docks, constructed in 1869. Pop. (1851) 5123; (1881) 6245. See Webb's *Memorials of Exmouth* (1873).

**Exmouth**, EDWARD PELLEW, VISCOUNT, an English admiral, was born at Dover, April 19, 1757. He entered the navy at the age of thirteen, and first attracted notice by his gallant conduct in the battle on Lake Champlain in 1776. In 1782 he attained the rank of post-captain. In 1793, having been appointed to the command of the *Nymphé*, a frigate of thirty-six guns, he encountered, and, after a hard-fought battle, captured *La Cléopâtre*, a superior French frigate. For this victory he was knighted; and in 1796, for acts of personal bravery, he was created a baronet. In 1798 he received the command of the *Impétueux*, and was sent to the French coast, where many of his most brilliant actions took place. In 1804 he was appointed rear-admiral of the Blue, and commander-in-chief in India, from whose seas he drove the French cruisers; he was afterwards made commander-in-chief in the North Sea and in the Mediterranean. In 1814 Pellew was created Baron Exmouth of Canonteign, in Devonshire, with a pension of £2000 a year. In 1816 he was sent to Algiers, to enforce the terms of a treaty regarding the abolition of Christian slavery, which the Dey had violated. With a combined fleet of twenty-five English and Dutch vessels, he bombarded the city for nine hours, and inflicted such immense damage, destroying all the Algerine fleet and many of the public buildings, that the Dey consented to every demand. For this service he was raised to the rank of viscount. He died 23d January 1833. See his *Life* by Osler (1835).

**Exocetus**. See FLYING-FISH.

**Exodus**, the second book of the Pentateuch, takes its name from a Greek word which means 'a going out,' 'a departure.' It relates the events connected with the sojourn of the people of Israel in Egypt, their departure from that country, their wanderings in the peninsula of Sinai, the promulgation of the moral code on Mount Sinai, together with the Mosaic laws of social observance, and the instructions for the building of the Tabernacle. The authorship of this book was traditionally assigned to Moses, to whom indeed the Jews attribute the five books of the Torah, or Pentateuch; but since the 17th century biblical critics have seriously questioned the correctness

of the tradition. The various views which have been held as to the composition of the book, the authorship of its different parts, and the dates at which they were probably written, will be found under BIBLE.

**Exogamy**, the usage by which in many primitive races a man is forbidden to marry a woman of his own stock or tribe. See MARRIAGE, and TRIBE.

**Exogenous Plants**, or EXOGENS, a term applied to dicotyledons by Lindley to express an erroneous view of the difference in the mode of stem-thickening from that of monocotyledons, and now wholly disused by botanists. See DICOTYLEDONS, also BARK, CAMBIUM, MONOCOTYLEDONS.

**Exophagy**. See CANNIBALISM.

**Exorcism**, the term used by the Fathers of the Church to denote the act of conjuring evil spirits, in the name of God or Christ, to depart out of the person possessed. The first Christians adjured evil spirits in the name of Jesus Christ, who had conquered the devil; but as the opinion was at the same time entertained that all idolaters belonged to the kingdom of Satan—who suffered himself to be worshipped under the form of idols—it was customary to exorcise heathens previous to their receiving Christian baptism. After Augustine's theory of original sin had found acceptance in the 5th century, and all infants were regarded as belonging to Satan's kingdom, exorcism became general at the baptism even of Christian children. Following the practice of the Roman Catholic Church, Luther retained it, and the baptismal office in the first prayer-book of Edward VI. (1549) contained a short form, omitted at Bucer's intervention in the 1552 revision. The seventy-second canon (1603) of the Church of England forbids any minister attempting to expel a devil or devils, without first obtaining the license of his bishop. Although abandoned by illustrious and orthodox Protestant theologians, such as Chemnitz and Gerhard, or deemed unessential, and in modern times done away with by the 'Protestant' Church, since 1822 baptismal exorcism has been revived by the Old Lutheran or High Church party.

In the Catholic Church the function of exorcism belongs peculiarly to the third of the so-called 'minor orders' (see ORDERS). Our Lord having not only himself in person (Matt. ix. 32; Mark, i. 25; Luke, iv. 35, viii. 29) cast out devils, but having also given the same power to his disciples, it is believed to be permanent in the church. Of its exercise in the early church, both in relation to 'energumens,' or persons possessed, and in the administration of baptism, there are numerous examples. Tertullian and Origen speak of it as of ordinary occurrence, and the Council of Carthage, in 255, alludes to its use in baptism. The rite of exorcism is used by the modern church in three different cases: in the case of actual or supposed demoniacal possession, in the administration of baptism, and in the blessing of the chrism or holy oil, and of holy water. This last practice is alluded to by Cyprian (Ep. 70). The use of exorcism in cases of possession is now extremely rare, and in many diseases is prohibited, unless with the special permission of the bishop. In baptism it precedes the ceremony of applying the water and the baptismal form. It is used equally in infant and in adult baptism, and Catholic writers appeal to the earliest examples of the administration of the sacrament as evidence of the use of exorcism in both alike. The rite of baptismal exorcism in the Roman Catholic Church follows closely the Scriptural model in Mark, viii. 33. The exorcisms in the blessing of the oil and water resemble very closely the baptismal form, but are more diffuse.

**Exosmose.** See ENDOSMOSE.

**Exostemma**, a West Indian genus nearly allied to *Cinchona*, for which its bark was formerly introduced as a substitute; it does not, however, contain the *Cinchona* alkaloids.

**Exostosis**, a term for a protuberance or morbid enlargement of a bone.

**Exoteric.** See ESOTERIC.

**Exotic Plants**, or EXOTICS (Gr., 'coming from abroad'), cultivated plants originally derived from foreign countries. The term is most frequently applied to those of which the native country differs so much in soil or climate from that into which they have been conveyed that their cultivation is attended with difficulty, requiring artificial heat or other means different from those requisite in the case of indigenous plants. See GARDENING.

**Expansion.** See HEAT, BRIDGE.

**Expectation of Life.** See PROBABILITY.

**Expectorants** (Lat. *ex*, 'out of,' and *pectus*, 'the breast'), medicines given to carry off the expectorations—the mucus and other secretions of the air-tubes. The principal expectorants are antimony, ammonia, squill, ipecacuanha, scroga, balsam of tolu, lobelia, gum ammoniac, asafoetida, galbanum, &c. The examination of the expectoration is of great value in the diagnosis of diseases of the chest (see BRONCHITIS, PNEUMONIA, CONSUMPTION). The word 'expectoration' has come by an abuse to be regarded as a mere elegant synonym for spitting. See SALIVA.

**Expenses or Costs of a Lawsuit.** In Scotland, the charges payable by the parties to a lawsuit are technically called expenses. The rules according to which they are awarded, apportioned between the parties, and taxed, do not differ materially from those applied in England to Costs, and explained under that head, *supra*. The Scottish official who discharges the functions of taxing master is the Auditor of Court. If the agent who has conducted the cause wish it, the decree for expenses will be pronounced in his favour; and the party found liable will not be allowed to plead a counter-claim against the client, as by that means he might prevent the agent from recovering what he very probably has disbursed.

**Experiment.** See SCIENCE.

**Expert**, a man of special practical experience or education in regard to a particular subject—a word commonly applied (after the French) to medical or scientific witnesses in a court of justice, when selected on account of special qualifications, as in the case of an analysis of the contents of the stomach in suspected poisoning. The term is similarly applied to a person professionally skilled in handwriting, for detection of forgery of deeds and signatures (see WRITING). It has been contended (see *Nature*, vol. xxxix. p. 589) that there should be experts specially retained to assist judges in cases where technical skill is necessary.

**Exploration.** See GEOGRAPHY.

**Explosions.** See MINING.

**Explosives**, a general term applicable to gunpowder, gun-cotton, dynamite, nitro-glycerine, and other explosive substances, treated in this work under their several heads (see also BLASTING, and FIRE-ARMS).

The law as to explosives is as follows: In general, whoever introduces explosives into a building is responsible for any damage they may cause. The tenant of a house is answerable for the damage caused by an explosion of gas on the premises, if gas escapes through the negligence of himself or his servants in attending to the stopcocks by which the supply of gas is regulated. Under the

Explosives Act, 1875, any person throwing, casting, or firing any fireworks in or into any highway, street, thoroughfare, or public place, is liable to a penalty of £5. Any person unlawfully and maliciously causing, or attempting or conspiring to cause, an explosion likely to endanger life or seriously to injure property is guilty of felony. It is also felony to make, keep, or have in one's possession any such explosive substance, except under the regulations of the statutes concerning this matter. The chief enactments are the Explosives Act (which regulates the manufacture, storage, keeping, selling, and conveyance of nitro-glycerine, dynamite, gun-cotton, and other explosives), the Petroleum Acts, 1871 and 1875, and the Petroleum (Hawkers) Act, 1881. All factories and stores of gunpowder and other explosives must be licensed, and all places where explosives are kept must be registered. The sale of gunpowder to any child apparently under thirteen is prohibited. Government inspectors, officers of local authorities, and constables may search for and seize explosives unlawfully kept, in ordinary cases with a warrant, and in cases of emergency with a written order from a superintendent of police. The master of every ship which enters a British harbour must, if the ship carry petroleum, give notice of the fact to the harbour authority, which, under confirmation of the Board of Trade, makes bylaws regulating the landing of petroleum. Petroleum to the amount only of three gallons may be kept for private use or sale without a license, if it is kept in separate glass, metal, or earthen vessels, securely stopped, and each containing not more than a pint.

**Exponents**, or INDICES. The product  $5 \times 5 \times 5 \times 5 \times 5$  is expressed thus,  $5^5$ , and the eighth power of  $a$  thus,  $a^8$ . The numbers 4 and 8 are the exponents of these respective powers. In general,  $a^n$  (where  $a$  is any number or expression) stands for the  $n$ th power of  $a$ —i.e. the product of  $n$  factors each =  $a$ , and there the value of this contracted notation is obvious. Introduced by Descartes, the theory of indices was speedily extended, and may now be said to affect algebraic operations of every conceivable kind. The two fundamental laws of indices are  $a^m \times a^n = a^{m+n}$ , and  $(a^m)^n = a^{mn}$ . These, with certain necessary conventions, apply to all possible values of the exponents  $m$  and  $n$ —integral or fractional, positive or negative, simple or complex, rational or surd, real or impossible, trigonometrical or logarithmic, &c. Minor results of the theory are such as these:

$a^0 = 1$ , whatever  $a$  may be;  $a^{-n} = \frac{1}{a^n}$ , or  $a^{-n}$  is the reciprocal of  $a^n$ ;  $a^{\frac{1}{2}} = \sqrt{a}$ ,  $a^{\frac{1}{3}} = \sqrt[3]{a}$ ,  $a^{\frac{1}{4}} = \sqrt[4]{a} = (a^{\frac{1}{2}})^{\frac{1}{2}}$ . An exponential equation is one in which the  $x$  or  $y$  occurs in the exponent of one or more terms, as  $5^x = 800$ . Its solution generally requires the use of logarithms. The exponential theorem gives a value of any number in terms of its natural logarithm, and from it can at once be derived a series determining the logarithm.

**Express**, in the United States, is specifically a system organised for the speedy transmission of parcels or merchandise of any kind, and their safe delivery in good condition. It originated in the trip made from Boston to New York by William Frederick Harnden (1813-45), the first 'express-package carrier,' on 4th March 1839. The project recommending itself to business men, competing companies sprang up rapidly, and express lines were established in all directions. Adams & Co.'s California express was started in 1849; Wells, Fargo, & Co.'s in 1852; the American-European company was created in 1855. As railways extended, the early 'pony express' disappeared, and individual companies now have

contracts with the several railway companies, their business over these routes being held to be entitled to the protection of the courts against any efforts to dispossess them. Many of the rival companies were amalgamated, and most of the successful concerns are now joint-stock institutions, the industry employing capital aggregating more than £10,000,000. A feature of the American express system is the 'collect on delivery' business, goods when sent to strange firms at a distance being marked C.O.D., with the amount to be collected on the outside of the package, and the payment being collected by the express company, which receives a slight compensation for this extra trouble. Also, the American Express Company issues, and has for sale at its 5500 offices throughout large sections of the East and West, money orders, which are payable at any of their offices, are received like cheques at all large banks (if handed in by depositors), and are generally preferred, as cheaper and safer than cheques or postal orders, for small remittances by mail. See A. L. Stimson's *History of the Express Business* (1883).

**Extension**, a term in Logic, opposed to *intension*, referring to the extent of the application of a term, or the number of objects included under it. The greater the extension of a term, the less is the intension; and the greater the intension or comprehension (the common characters included in a term), the less is the extension.

**Extent**. To extend is, in English law, to make a valuation of property by the oath of a jury. A writ of extent directs the sheriff to 'extend' and seize the property of a debtor. Such writs are now issued only for the recovery of debts of record due to the crown. In Scotland 'extent' (often shortened to 'stent') was used to denote the general valuation of lands for taxation, &c. For the old and new extent, see VALUATION OF LANDS. Writs of extent were formerly issued for the recovery of crown debts; and the English form of process was introduced, in revenue cases, by the Act of Union. In America extent is a process whereby the lands of a debtor are delivered to his creditor until the debt is paid out of the profits.

**Extenuating Circumstances**. When a crime is committed, those circumstances, in connection either with the position of the prisoner or with the act alone, which are taken into consideration by the court in mitigation of the punishment are popularly called extenuating circumstances. The previous good character of the person convicted may always be proved as a circumstance giving him some claim to leniency of punishment. Besides character, there are other circumstances, the presence of which in a case sometimes serves to mitigate the sentence, sometimes to take the act done out of the category of crime altogether. One is youth. Thus, no act done by any person under seven years of age is a crime. Defective mental power in the person convicted will always be considered in determining the severity of his sentence. Such disease of mind as prevents a man from knowing that the act he does is wrong will excuse him from the consequences of an act otherwise criminal. Thus, if one man kill another under the insane delusion that he is breaking a jar, the act is not a crime. Drunkenness, when voluntary, is not held an extenuating circumstance, but if a man is made drunk by the fraudulent administration of drugs, and while under their influence kills another, not knowing what he does, the act is not a crime. It is a good excuse for persons charged with crime that they have been compelled by others by threats of death or great violence to do the criminal act; and the acts of a married woman in presence of her husband are presumed to be done

under his coercion, and so, unless the presumption is rebutted, will be excused. Ignorance of the law is no excuse for an offence. Thus, a foreigner, not knowing the law of England, might kill a man in a duel, and suppose that he had done nothing unlawful. But he would be guilty of murder. Nor, in general, will ignorance of facts be a good excuse, although in particular circumstances it might form a valid defence. Thus, if a man pretended in a joke to be a robber, presented a pistol at the head of a traveller, and demanded his money, and the traveller, believing himself to be attacked by a real robber, shot and killed the pretended robber, his act would be held as justified. Sir James Fitzjames Stephen (*Digest of the Criminal Law*, 1887) states, in language purposely vague, to represent the vagueness of the law, a principle under which the stress of necessity is held to excuse acts otherwise criminal. He says: 'An act which would otherwise be a crime may in some cases be excused if the person accused can show that it was done only in order to avoid consequences which could not otherwise be avoided, and which, if they had followed, would have inflicted upon him or upon others whom he was bound to protect inevitable and irreparable evil, that no more was done than was reasonably necessary for that purpose, and that the evil inflicted by it was not disproportionate to the evil avoided.' He gives as an illustration of the principle the case of a governor of Madras who acted towards his council in an arbitrary and illegal manner. The council deposed him and put him under arrest, and assumed the powers of government themselves. That was not an offence if the acts done by the council were the only means by which irreparable mischief to the establishment at Madras could be avoided. He also gives as a further illustration the often figured case of the plank. 'A and B, swimming in the sea after a shipwreck, get hold of a plank not large enough to support both; A pushes off B, who is drowned. This is not a crime.' The principle, however, was not held to cover the case of shipwrecked sailors who killed a boy in order to eat his body, without which they would probably not have survived.

**Extincteur**. See FIRE.

**Extortion**, in Law, is the offence or illegal act committed by a public officer who, under colour of his office, takes from any person any money or valuable thing which is not due from him at the time when it is taken. The act is a misdemeanour, and punishable as such. For example, if the governor-general of India wrongfully compel a native prince to pay sums of money to the Indian government (as was the charge against Warren Hastings), he commits extortion. The term has a special meaning in the criminal law of Scotland, in which it is also applied to the offence of compelling any one by force or fear to do any act which he would not have done of his own consent and inclination. For extortion in the sense of blackmailing, see THREAT.

**Extractive Matter** is the term applied to the soluble portions of any drug. The substances extracted from the same drug may vary according as the solvent is water, alcohol, ether, &c.; but, so long as the originally insoluble portions are not rendered soluble by the chemical action of the solvent, the term extractive matter is applicable to them.

**Extracts**, in a technical sense, are medicinal preparations of vegetable principles, got either by extracting these from the plants by means of a solvent or menstruum, and then evaporating the liquid down to about the consistency of honey, or by expressing the juice of the plants and evaporating; this last is properly *inspissated juice*. Extracts,

therefore, contain only those vegetable principles that are either held in solution in the juices of the plants themselves, or are soluble in the liquid employed in extracting them, and at the same time are not so volatile as to be lost during evaporation. Now, as many extractive matters are more or less volatile, it makes a great difference whether the operation is conducted at a low or at a high temperature. Besides the loss of volatile constituents by prolonged or excessive heating, extracts become more or less changed and inert owing to the readiness with which vegetable principles are destroyed when exposed to heat and air. On this account it is usual to avoid evaporation as much as possible, and, where this is impracticable, evaporation *in vacuo* is resorted to. Extracts are called *watery* or *alcoholic* according as the menstruum employed is water or alcohol. Ether is also used in extracting. Different plants, of course, afford different extracts, some being of the nature of bitters, others being used as pigments, tannin, &c.

*Liquid extracts* are those which are not evaporated so far as to form a paste, and it is usual to make them of such a strength that one fluid ounce contains the active ingredients of one ounce by weight of the drug.

**EXTRACT OF MEAT** is obtained by acting upon chopped meat by cold water, and gradually heating, when about one-eighth of the weight of the meat dissolves out, leaving an almost tasteless insoluble fibrin. The extract of meat contains the salts and savoury constituents of the meat, and is a light and stimulating article of food (see **BEEF-TEA**, and **BROTH**). It may be concentrated into small bulk, and, when desired, may be afterwards treated with water; being heated, it forms an agreeable light soup, though rather stimulating than nutritious. Of this nature is the well-known Liebig's Extract. In order to impart to extract of meat a nutritive as well as stimulant value, the fibrin is sometimes dried and powdered, and, when then incorporated with the extract itself, a product is obtained which represents the original meat in a readily digested form.

**Extradition** is the surrender of a person accused of crime to the government of a foreign country, within which the crime is alleged to have been committed. The duty of making such surrender has long been acknowledged by civilised nations; but some governments refuse to surrender their own subjects when accused of offences against a foreign law. In England it has been held that no executive officer has authority to surrender any person found within Her Majesty's dominions unless empowered to do so by act of parliament. Modern facilities for travelling have made extradition a subject of great importance. In 1843 the British government concluded an extradition treaty with France, and parliament passed an act giving the executive the necessary powers. Since that time treaties have been made by all, or almost all, civilised governments for the surrender of criminals. It is commonly supposed that some countries (Spain, for example) afford a safe refuge for criminals; but the British government concluded an extradition treaty with Spain in 1878, and even before the treaty offenders were given up to justice by the Spanish government. See the case of Bidwell, the bank-forgery, in 1872. The practice of the British government is regulated by the Extradition Acts of 1870 and 1873. The extradition treaty between Britain and the United States was concluded in 1842, with France in 1843, and with Germany in 1872. Any police-magistrate may order the detention of a person accused of crime committed abroad on the same evidence which would justify committal of a person accused of crime committed in England. But the person

detained is not surrendered until a demand has been addressed to a secretary of state by a diplomatic representative of the government making the demand. The secretary of state may direct a magistrate to inquire into the case; and on such inquiry the prisoner may show that the evidence against him is not sufficient to justify his committal and surrender for trial, or that the crime of which he is accused is not an 'extradition crime'—i.e. not within the treaties and acts which apply to the case. The list of extradition crimes, as fixed by the Act of 1870, includes murder, manslaughter, forgery, larceny, frauds by bankers, extortion by threats, and many other offences. If the magistrate certifies that he has committed the accused, the secretary of state gives a warrant for his surrender; but not until fifteen days have elapsed; during this interval the prisoner may, if so advised, apply to a superior court for a *habeas corpus*. Political offences are expressly excluded from the category of 'extradition crimes'; but it is to be observed that a political offence does not mean an offence committed from political motives, but an offence committed during a time of civil war or open insurrection (see **POLITICAL OFFENCES**, **REFUGEE**). A person surrendered on a specific charge may not be tried on any other charge. In 1877 a Royal Commission, appointed to consider the law of extradition, presented a report in which certain reforms were suggested, which have not yet been carried out. The Commission recommended that treaties should not be considered indispensable, and that British subjects should be surrendered as well as foreigners. It happens sometimes that the person whose surrender is demanded is not a subject of either government—a Spanish subject, for example, may commit crimes in Russia and take refuge in England. In this case the British government would probably not surrender the accused to Russia without obtaining the consent of Spain. In the United States offenders from one state taking refuge in another are usually surrendered by the governor thereof without question; but even in such cases constitutional points of considerable difficulty have sometimes arisen.

See E. Clarke's *Treatise on Extradition* (2d ed. 1874); Kirchner's *Law and Practice relative to Fugitive Offenders* (1882); and *Recueil de tous les Traités, &c.* (1883); and Herslet's *Treaties and Laws relating to Commerce, Extradition, &c.* (1885).

**Extravasation** is the escape of any of the fluids of the living body from their proper vessels (*vas*) through a rupture or injury in their walls. Excrementitious matter thus sometimes escapes into the abdomen through a wound or ulceration of the bowels. But the term is oftener used in speaking of the escape of blood from injured blood-vessels. Extravasation is distinguished from exudation by this, that in the last the vessels remain entire, and the effusion takes place by filtration through their walls; nor does more than a part of the blood so escape, the coloured blood-corpuscles being retained, while in extravasation perfect blood is effused. Many kinds of extravasation are rapidly fatal, such as that of urine or of the contents of the intestines into the abdomen, or of blood from the vessels of the brain in cases of apoplexy. The dark colour resulting from a bruise is owing to extravasated blood from ruptured capillary or larger vessels.

**Extreme Unction**, a sacrament of the Roman Catholic Church, which, as the other sacraments supply spiritual aid in the various circumstances of life, is believed to impart to the Christian in death grace and strength to encounter the struggle, as well spiritual as bodily, of the dying hour. The rite of unction in different forms is common to several of the sacraments; the name 'extreme' is

given to that of the present sacrament, because it is reserved for the last act of the Christian career. The Council of Trent declares this sacrament, although 'promulgated' in the well-known passage of James, v. 14, 15 (which Protestants regard as having more to do with the general belief in the sanative properties of oil), to have been 'instituted' by Christ. The Fathers frequently allude to the rite of unction, and although many of these allusions certainly refer to the unctions of baptism and confirmation, yet Catholics rely on several passages of Origen, Chrysostom, Cæsarius of Arles, and Pope Innocent I. as decisive regarding the unction of the dying, as also upon the fact that in the various separated churches of oriental Christians—Greek, Coptic, Armenian, and Nestorian—the rite is found, although with many ceremonial variations. In the Roman Catholic Church the sacrament is administered by the priest, who, 'dipping his thumb in the holy oil, anoints the sick person, in the form of the cross, upon the eyes, ears, nose, mouth, hands, and feet; at each anointing making use of this form of prayer: "Through this holy unction, and His most tender mercy, may the Lord pardon thee whatever sins thou hast committed by seeing, Amen." And so of hearing, smelling, taste and speech, touch, and walking, adapting the form to the several senses.' Extreme unction is reputed by Catholics one of the sacraments 'of the living;'—i.e. it ordinarily requires that the recipient should have previously obtained remission of his sins by absolution or by perfect contrition; but it is held to remit, *indirectly*, actual sins not previously remitted, and also (although not infallibly, but according to the merciful designs of Providence) to alleviate, and even to dispel, the pains of bodily disease. The holy oil which forms the 'matter' of this sacrament must be blessed by the bishop—a ceremony which is performed with great solemnity once each year by the bishop, attended by a number of priests, on Maundy-Thurs day. The oil so blessed is reserved for use during the year. In the Greek Church the sacrament is administered by several priests conjointly. The Greeks call this sacrament 'The Holy Oil,' and sometimes 'The Oil of Prayer.'

**Exumas**, comprising Great Exuma, Little Exuma, and the Exuma Keys, form part of the group of the Bahama Islands (q.v.).

**Exuviae**, a term applied to organic remains, now seldom employed, but frequently used by the older geologists.

**Eyam** (pronounced as if *Eem*), a village in North Derbyshire, 5 miles N. of Bakewell, with a population of 1038, chiefly engaged in lead-mining. Here broke out in September 1665, in its most virulent form, the plague which was then raging in London, and which had been carried hither in a box of clothes and tailor's patterns. William Mompesson, the rector of the parish, aided by Thomas Stanley, who had been ejected in 1662, devoted himself to the care of the dying with the most heroic courage. The plague lingered till the middle of October 1666, and as many as 260 out of a population of 350 perished. Another rector of Eyam achieved a less honourable eminence by living in his vestry for years to evade the consequences of a breach of promise case. Here he defied the law until his death in 1705. See W. Wood's *History of Eyam* (4th ed. 1865).

**Eyck**, HUBERT and JAN VAN, two illustrious painters of the early Flemish school. They were probably born at Alden Eyck or Maas Eyck on the Maas. The date of their birth is uncertain; but Hubert is supposed to have been born about 1370, and Jan about 1389. The distinction of being the inventors of oil-painting is claimed for them,

though sufficient evidence has been adduced to show that the method was practised previously. Before their time, however, the custom, particularly in Italy, was to paint with gums or other substances of an adhesive nature dissolved in water, and they were the first who brought into notice and perfected the mode of mixing colours with oil or some medium in which oil was the chief ingredient; while for transparent and brilliant colouring and minute finish their works have never been surpassed. Jan appears to have been instructed in art by his elder brother, and to have painted in conjunction with him as court-painter to Philip of Charolais till 1422, when he entered the service of John of Bavaria, Count of Holland, at the Hague; and in 1425 he was appointed painter and valet-de-chambre to Philip the Good, Duke of Burgundy, and practised his art chiefly at Bruges. Hubert continued to reside at Ghent, and at the time of his death, on 18th September 1426, was engaged upon a very important altarpiece, with folding-doors, the only work which we can certainly assign to him, and which was completed by his brother. Its subject was 'The Adoration of the Lamb,' and it was painted for Jodocus Vydyts, who presented it to the cathedral of St Bavon in Ghent. The two central divisions of this picture are all that now remain in the church at Ghent, the wings being in the Gallery at Berlin, with the exception of those representing Adam and Eve, which are in the Brussels Museum. The masterpieces of the brothers are for the most part in the cities of Ghent, Bruges, Antwerp, Berlin, Munich, and Paris. In the National Gallery, London, there are three pictures of Jan van Eyck, which well exemplify the high qualities of his art. These are portraits of Jenn Arnolfini and Jeanne de Chenamy, his wife, standing in the middle of an apartment, with their hands joined—signed and dated 1434; the portrait of a man in a cloak and fur collar, with a red handkerchief twisted round the head as a turban—painted, according to an inscription on the lower part of the frame, October 21, 1433; and the portrait of a man with a dark-red dress and a green head-covering—signed and dated 10th October 1432. In the Louvre is his exquisitely finished little picture of 'Chancellor Rolin kneeling before the Virgin.' Jan died at Bruges, 9th July 1440.

MARGARET VAN EYCK, a sister of the two above painters, is mentioned as an excellent artist by Lucas de Heere and Van Manden. A 'Virgin and Child,' in the National Gallery, London, was formerly assigned to her, but in the catalogue of 1839 is attributed to an unknown painter of the Early Flemish school; and she is believed to have executed the miniatures in the missal of the Duke of Bedford. She died before 1431. See Crowe and Cavalcaselle, *Early Flemish Painters* (3d ed. 1879).

**Eyc** (A.S. *ig*, 'an island'), a market-town and municipal borough in Suffolk, 20 miles N. of Ipswich. It has a fine Perpendicular flint-work church (restored 1869), with a tower 101 feet high, a corn exchange and town-hall (1857), a grammar-school (restored and enlarged, 1876-82), and a station at the terminus of a short branch-railway. Till 1885 it returned a member to parliament. Pop. (1851) 2587; (1881) 2296.

**Eye**. In this article we shall consider: (1) The structure of the human eyeball, and of certain accessory parts or appendages which serve to protect that organ, and are essential to the due performance of its functions. (2) The most striking modifications which this organ presents in some of the lower animals. (3) The eye considered as an optical instrument. (4) The action of the retina. (5)

The movements of the eyeballs, and binocular vision.

(1) The *globe of the eye* is placed in the anterior part of the cavity of the orbit, in which it is held in position by its connection with the optic nerve posteriorly, by the muscles which surround it, and by the eyelids in front. It is further supported behind and on the sides by a quantity of loose fat, which fills up all the interstices of the orbit, and facilitates the various movements of which the eye is capable.

The form of the eyeball is nearly spherical; but on viewing the organ in profile we see that it is composed of segments of two spheres of different diameters. Of these, the anterior, formed by the transparent cornea, is more curved, and therefore more prominent. The horizontal transverse diameter

Fig. 1. - View of lower half of right Human Eye, divided horizontally:

*a*, cornea; *b*, sclerotic; *c*, sheath of optic nerve passing into sclerotic; *d*, choroid; *e*, ciliary muscles; *f*, ciliary process; *g*, *g*, iris; *h*, optic nerve with artery in centre; *i*, passage of nerve into retina, called optic disc or papilla; *k*, fovea centralis; *l*, retina; *m*, vitreous chamber of eye; *n*, aqueous humour.

humour

is almost exactly an inch; the antero-posterior and vertical each about  $\frac{1}{8}$  less. The radius of the posterior or sclerotic segment is about half, and that of the anterior segment about three-tenths of an inch.

When the eyes are in a state of repose, their antero-posterior axes are parallel; the optic nerves, on the other hand, diverge considerably from their commissure within the cavity of the skull to the point where they enter the globe; consequently their direction does not coincide with that of the eye. Each nerve enters the back of the globe at a distance of about one-eighth of an inch on the inner side of the antero-posterior axis of the eye.

The eyeball is composed of three concentric membranes, and of certain transparent structures, which are inclosed within them, and which, together with the cornea, transmit and refract the rays of light which enter the eye.

The outer (fibrous or protective) membrane consists of the sclerotic and cornea; the middle (vascular or nutritive) of the choroid and iris; the inner (nervous or percipient) of the retina. The transparent contents are (from before backwards) aqueous humour, crystalline lens, and vitreous humour. We shall consider these structures in order.

The *sclerotic* (from *skleros*, 'hard'), or 'white of the eye,' is a strong, dense, fibrous structure, covering about five-sixths of the eyeball, and continuous, anteriorly, with the cornea. Posteriorly, it is perforated by the optic nerve, and it is there continuous with the sheath which that nerve derives from the dura mater, the fibrous investment of the brain and spinal cord. Near the entrance of the nerve, its thickness is about  $\frac{1}{8}$ th of an inch; from this it diminishes to about  $\frac{1}{10}$ th; but in front it again becomes thicker, from the tendinous insertions of the straight muscles which blend with it.

The *cornea* (so called from its horny appearance) is a transparent structure, continuous with the sclerotic, from which it differs more in appearance than in texture, and completing the fibrous tunic of the eye anteriorly. Its circumference is overlaid by the free edge of the sclerotic, as 'a watch-glass by the edge of the groove into which it is received.' Its thickness is from  $\frac{1}{10}$ th to  $\frac{1}{8}$ th of an inch. It is covered in front by a layer of conjunctival epithelium, which is exquisitely sensitive.

The cornea, in consequence of its greater convexity, projects beyond the line of the sclerotic; the degree of convexity, however, varies slightly in different persons, and at different periods of life. It is so strong as to be able to resist a force capable of rupturing the sclerotic. The fibrous coat, by its great strength and comparatively unyielding structure, maintains the inclosed parts in their proper form, and serves to protect them from external injuries.

The *choroid coat* is a dark-coloured vascular membrane, which is brought into view on the removal of the sclerotic. Its outer surface, which is nearly black, is loosely connected with the sclerotic by connective tissue, in which are contained certain nerves and vessels—termed the ciliary nerves and vessels—some of which go forward to the iris. Its inner surface is smooth and dark-coloured. In front, it terminates in the *ciliary processes* (figs. 1 and 3), which consist of about sixty or seventy radiating folds or thickenings of the membrane, each of them terminated by a small free interior extremity, and lodged in a corresponding fold in the suspensory ligament of the lens. In other parts, it is covered by the

Fig. 2. - Choroid and Iris, exposed by turning aside the sclerotic:

*a*, *a*, ciliary nerves going to be distributed in iris; *d*, *d*, smaller ciliary nerves; *e*, *e*, veins known as vasa vortices; *h*, ciliary muscle; *k*, *k*, converging fibres of iris; *o*, optic nerve.

hexagonal pigment-cells of the retina. The choroid is composed of minute ramifications of vessels—

especially of veins, which, from their whirl-like arrangement, are termed *vasa vorticosa*—of connective tissue, and of large branching pigment-cells. Between the sclerotic and choroid at its anterior part lies a small but important structure, the *ciliary muscle*, which arises from the inner surface of the sclerotic near the cornea, and passes backwards to be inserted into the choroid opposite the ciliary processes.

The *iris* may be regarded as a process of the choroid, with which it is continuous, although there are differences of structure in the two mem-

branes. It is a thin flat membranous curtain, hanging nearly vertically in the aqueous humour in front of the lens, and perforated by the pupil for the transmission of light. Its anterior surface is variously coloured, and covered by fine irregularly-radiating projections; its posterior surface is smooth, and covered by a

Fig. 3.—Iris and Ciliary Processes from behind:

a, posterior surface of the iris, with the sphincter muscle of the pupil; b, anterior part of the choroid coat; c, one of the ciliary processes, of which about seventy are represented; d, the pupil.

uniform layer of dark pigment, continuous with the pigment-cells of the retina. The posterior surface near the pupil is in contact with the anterior capsule of the lens. It divides the space between the cornea and the lens into an anterior (the larger) and a posterior (the smaller) chamber, these two chambers freely communicating through the pupil (see fig. 1). The outer and larger border is attached all round near the line of junction of the sclerotic and cornea, to the cornea, choroid, and ciliary muscle, while the inner edge forms the boundary of the pupil, which is nearly circular, lies a little to the side of the centre of the iris, and varies in size according to the action of the muscular fibres of the iris, so as to admit more or less light into the interior of the eyeball; its diameter varying, under these circumstances, from about  $\frac{1}{10}$  to  $\frac{1}{8}$  of an inch. It is muscular in its structure, one set of fibres being arranged circularly round the pupil, and, when necessary, effecting its contraction, while another set lie in a radiating direction from within outwards, and by their action dilate the pupil. These fibres are of the unstriped or involuntary variety. The nerves which are concerned in these movements will be presently noticed. The iris is richly supplied with blood-vessels; and pigment-cells like those of the choroid are scattered through its substance.

The varieties of colour in the eyes of different individuals, and of different kinds of animals, mainly depend upon the colour and amount of the pigment in these cells. In blue eyes, this pigment is scanty or absent, and the colour is due to the dark pigment of the posterior surface partly seen through the vascular membrane; in brown and black eyes, it is abundant, and is the cause of the colour. In albinos, this pigment is absent from iris, retina, and choroid, and hence their eyes have a pink appearance, which is due to the unconcealed blood in the capillaries of the choroid and iris.

Within the choroid is the *retina*, which, although

continuous with the optic nerve—of which it is usually regarded as a cuplike expansion—differs very materially from it in structure. Before noticing the elaborate composition of this part of the eye, which has only been revealed by microscopical investigation, we shall briefly mention those points regarding it which can be established by ordinary examination. It is a delicate semi-transparent sheet of nervous matter, lying immediately behind the vitreous humour, and extending from the optic nerve nearly as far as the lens. On examining the concave inner surface of the retina at the back of the eye (see fig. 4), we observe, directly in a line with the axis of the globe, a circular yellow spot (*macula lutea*), of about  $\frac{1}{16}$ th of an inch in diameter, called, after its discoverer, the *yellow spot of Sommering*, with a depression in its centre, the *fovea centralis*. About  $\frac{1}{4}$ th of an inch internal to this is the entrance of the optic nerve, called the *optic disc* or *papilla*, from which the central artery and vein of the retina may be seen branching as they pass to their distribution.

Fig. 4.—Posterior half of left Eye from the front:

a, cut edge of sclerotic; b, of choroid; c, of retina; d, macula lutea; e, optic disc or papilla.

The structure of the retina, as revealed by the microscope, is in the highest degree remarkable (see fig. 5). Although its greatest thickness (at the entrance of the optic nerve) is only about  $\frac{1}{16}$ th of an inch, and as it extends anteriorly, it soon diminishes to  $\frac{1}{32}$ th of an inch, the following layers from without inwards can be distinguished in most parts of it: (a) The pigmentary layer, consisting of a single layer of flat hexagonal cells, regularly arranged; its outer surface closely connected with the choroid, its inner in contact with the extremities of the rods and cones. Though its development shows that it really belongs to the retina, its mechanical connection with the choroid is firmer; and to this it adheres when the retina is stripped off. (b) The layer of rods and cones, frequently termed, from its discoverer, the *membrane of Jacob*; (c) outer granular layer; (d) outer molecular; (e) inner granular; (f) inner molecular; (g) layer of nerve-cells; (h) layer of nerve-fibres, in which the blood-vessels lie.

Fig. 5.—Diagrammatic Section of Human Retina.

The layer of rods and cones, the portion of the eye which receives the impressions of light, deserves special attention. The rods are thinner but longer than the cones, and in most parts of the retina far more numerous. At the yellow spot, however, only cones are found. Each rod or cone consists of a thicker inner portion, connected with the outer granular layer, and ultimately with the optic nerve by a fine fibril; and an outer thinner part, directed towards and connected with the pigmentary layer. The percipient elements are thus directed away from, not towards the light. 'In fact, we do not look outwards at the actual object, but we see the object as reflected from the base of our own eye.' Of the cones there are several, of the rods many millions in each human eye, and they are closely packed together over the whole extent of the retina.

It now remains for us to describe the *transparent media* which occupy the interior of the globe, and through which the rays of light must pass before they can reach the retina, and form on it the images of external objects. We shall consider them in the order in which the rays of light strike them.

Immediately behind the transparent cornea is the *aqueous humour*, which fills up the anterior and posterior chambers which lie between the cornea and the lens. As its name implies, it is very nearly pure water, with a mere trace of albumen and chloride of sodium. It is believed to be secreted by the choroid and to pass forward from it through minute lymphatic channels.

The *crystalline lens* lies opposite to and behind the pupil, in contact with the inner part of the iris, and its posterior surface is received into a corresponding depression on the forepart of the vitreous humour (see fig. 1). In form, it is a double-convex lens, with surfaces of unequal curvature, the posterior being the most convex. It is inclosed in a transparent capsule, of which the part covering the anterior surface is nearly four times thicker than that at the posterior aspect. The microscopic examination of the substance or body of the lens reveals a structure of wonderful beauty. Its whole mass is composed of extremely minute elongated ribbon-like structures, commonly called the *fibres of the lens*. These fibres are arranged side by side in lamellae, of which many hundred exist in every lens, and which are so placed as to give to the anterior and posterior surfaces the appearance of a central star, with meridian lines. The lens gradually increases in density, and at the same time in refracting power, towards the centre; by this means, the refracting power is made greater than it would be even if the lens had throughout the same index of refraction as the nucleus. (According to the latest measurements, the index of refraction of the outer layer is 1.393; of the nucleus, 1.431; the total refractive power corresponds to that of a homogeneous body of the same size and shape with index 1.448.) This arrangement besides corrects to a certain extent the spherical aberration of the eye. According to Berzelius, the lens contains 58 per cent. of water, 36 of albumen, with minute quantities of salts, membrane, &c. In consequence of the albumen, it becomes hard and opaque on boiling, as we familiarly see in the case of the eyes of boiled fish. In the adult, its diameter transversely is about  $\frac{1}{4}$  in., and its thickness antero-posteriorly about  $\frac{1}{16}$  of an inch; and it weighs three or four grains. The lens is held in position by the *suspensory ligament* of the lens and *zonule of Zinn*, a fine transparent fibrous structure, attached outwardly to the choroid between the ciliary processes, and passing inwards to blend with the anterior and posterior capsule of the lens near its margin (see fig. 1).

The *vitreous humour* lies in the concavity of the retina, and occupies about four-fifths of the eye posteriorly. Its form is shown in fig. 1. It is inclosed, except in front, in the hyaloid membrane, which blends anteriorly with the zonule of Zinn; and its anterior surface is in contact with the posterior capsule of the lens. It is quite transparent, and of a soft gelatinous consistence. Its outer part at least is laminated, like the coats of an onion. But the exact arrangement of the framework which gives it its consistence has not been determined. Between the anterior border of the retina and the border of the lens, we have a series of radiating folds or plaitings termed the *ciliary processes of the vitreous body*, into which the *ciliary processes of the choroid* dovetail. The vitreous humour contains, according to Berzelius, 98.4 per cent. of water with a trace of albumen and salts, and hence, as might be expected, its refractive index is almost identical with that of water.

The appendages of the eye now claim our notice. The most important of these appendages are the *muscles within the orbit*, the *eyelids*, the *lacrimal apparatus*, and the *conjunctiva*, to which (although less important) we may add the *eyebrows*.

The *muscles* by which the eye is moved are four straight (or *recti*) muscles, and two oblique (the superior and inferior). The former arise from the margin of the optic foramen at the apex of the orbit, and are inserted into the sclerotic near the cornea, above, below, and on either side. The superior oblique arises with the straight muscles; but after running to the upper edge of the orbit, has its

Fig. 6.—Muscles of Right Eyeball:

The external rectus muscle divided to show the optic nerve, which has also been cut to show the internal rectus muscle.

a, nasal bone; b, levator palpebrae superioris; c, superior oblique; d, superior rectus; e, external rectus; f, internal rectus; g, inferior rectus; h, optic nerve; i, inferior oblique; j, pulley; k, tarsal cartilage.

direction changed by a pulley, and proceeds backwards, outwards, and downwards (see fig. 6). The inferior oblique arises from the lower part of the orbit, and passes backwards, outwards, and upwards. The action of the straight muscles is sufficiently obvious from their direction: when acting collectively, they fix and retract the eye; and when acting singly, they turn it towards their respective sides. The oblique muscles antagonise the recti, and draw the eye forwards; the superior, acting above, directs the front of the eye downwards and outwards, and the inferior upwards and inwards. By the duly associated action of these muscles, the eye is enabled to move (within definite limits) in every direction.

The *eyelids* are two thin movable folds placed in front of the eye, to shield it from too strong light, and to protect its anterior surface. They are composed of (1) skin, with a layer of muscle (part of the *orbicularis*, see below) closely adherent to it; (2) of a thin plate of fibro-cartilage, termed

the *tarsal cartilage*, the inner surface of which is grooved by thirty or forty parallel vertical lines, in which the Meibomian glands are imbedded; and (3) of a layer of mucous membrane (*conjunctiva*), continuous, as we shall presently see, with that which lines the nostrils, and joining the skin at the margin of the lids, in which the eyelashes (*cilia*) are arranged in two or more rows. The upper lid is much the larger; and to the posterior border of its cartilage a special muscle is attached, termed the *levator palpebræ superioris*, whose object is to elevate the lid, and thus open the eye; while there is another muscle, the *orbicularis palpebrarum*, which surrounds the orbit and eyelids, and by its contraction closes the eye. The Meibomian glands secrete a sebaceous matter,

Fig 7.

#### The Appendages of the Eye:

1, the cartilage of the upper eyelid; 2, its lower border, showing the openings of the Meibomian glands; 3, the cartilage of the lower eyelid, also showing on its border the openings of the Meibomian glands; 4, 5, the lacrimal gland; 6, its ducts; 7, the plica semilunaris; 8, the caruncula lacrimalis; 9, the puncta lacrimalia, opening into the lacrimal canals; 10, 11, the superior and inferior lacrimal canals; 12, the lacrimal sac; 13, the nasal duct, terminating at 14 in the lower meatus of the nose.

pass from the sac into the nose. The gland is an oblong body, about the size of a small almond, lying in a depression in the upper and outer part of the orbit. The fluid secreted by it reaches the surface of the eye by twelve or fourteen ducts, which open on the conjunctiva at its upper and outer part. The constant motion of the upper eyelid induces a continuous gentle current of tears over the surface, which carry away any foreign particle that may have been deposited on it. The fluid then passes through two small openings, termed the *puncta lacrymalia* (see 9 in fig. 7), into the canals; whence its further course into the lower portion of the nose is sufficiently obvious from the figure. The conjunctiva (or mucous coat) which covers the front of the eyeball, and lines the inner surface of the lids, passes down and lines the canals, sac, and duct; and is thus seen to be continuous with the nasal mucous membrane, of which it may be regarded as an offshoot or digital prolongation.

We shall conclude this sketch of the anatomy of the human eye by a brief notice of the *nerves* going to this organ and its appendages. Into each orbit there enters a nerve of *special sense*—viz. the optic nerve; a nerve of *ordinary sensation*—viz. the ophthalmic branch of the fifth nerve; and certain nerves of *motion* going to the muscular tissues, and regulating the movements of the various parts—viz. the third, fourth, and sixth nerves.

As the optic tracts from which the *optic nerves* originate are noticed in the article *BRAIN*, we shall merely trace these nerves from their *chiasma* or commissure forwards. This commissure results

from the junction of the optic tracts of the two sides; and it is especially remarkable for the fact that it presents a partial decussation of the nervous fibres; the central fibres of each tract passing into the nerve of the *opposite* side, and crossing the corresponding fibres of the other tract, while the outermost fibres, which are much fewer in number than the central ones, pass to the optic nerve of the *same* side. In front of the commissure, the nerves enter the optic foramen at the apex of the orbit, receive a sheath or investment from the *dura mater*, acquire increased firmness, and finally terminate in the retina. The peculiar mode of termination of the optic nerves in the cuplike expansion of the retina, the impairment or loss of vision which follows any morbid affection of them, and the constant relation in size which is observed in comparative anatomy between them and the organs of vision, afford sufficient evidence that they are the proper conductors of visual impressions to the sensorium.

The first or ophthalmic division of the fifth or trifacial nerve sends branches to the eyeball (ciliary nerves), to the skin of the eyelids, and to the conjunctiva. That it is the nerve of ordinary sensation of the eye is sufficiently obvious from the following facts: (1) That in disease of this nerve in the human subject, it is not uncommon to find the surface of the eyeball totally insensible to every kind of stimulus (particles of dust, pungent vapours, &c.); and (2) that if the nerve be divided in the cranium (in one of the lower animals), similar insensibility results.

The most important of the nerves of motion of the eye is the third nerve, or *motor oculi*. It supplies with motor power the elevator of the upper eyelid, and all the muscles of the globe, except the superior oblique and the external straight muscle, and, in addition to this, it sends filaments to the iris and ciliary muscle within the eye. The application of an irritant (in vivisection experiments) to its trunk induces convulsive contraction of the principal muscles of the ball and of the iris; while paralysis or division of the trunk occasions an external squint, with palsy of the upper eyelid and fixed dilatation of the pupil. The squint is caused by the action of the external straight and the superior oblique muscles, while the other muscles are paralysed by the operation. The normal motor action of the nerve upon the iris, in causing contraction of the pupil, is excited through the optic nerve, and affords a good illustration of *Reflex Action* (q.v.); the stimulus of light falling upon the retina, and, through it, exciting that portion of the brain from which the third nerve takes its origin. This nerve clearly exerts a double influence in relation to vision: (1) it mainly controls the movements of the eyeball and the upper eyelid; and (2) from its connection with the muscular structures in the interior, it regulates the amount of light that can enter the pupil, and the adjustment of the eye to various distances. The fourth nerve supplies the superior oblique muscle with motor power, while the sixth nerve similarly regulates the movements of the external straight muscle—the only two muscles in the orbit which are not supplied by the third pair. Although not entitled to be termed a nerve of the orbit, the facial nerve deserves mention as sending a motor branch to the *orbicularis* muscle, by which the eyelids are closed.

(2) *Comparative Anatomy of the Eye.*—In mammals, the structure of the eye is usually almost identical with that of man. The organ is, however, occasionally modified, so as to meet the peculiar wants of the animal. Thus, in the Cetacea, and in some amphibious Carnivora that catch their prey in the water, the shape of the lens

is nearly spherical, as in fishes, and there is a similar thickening of the posterior part of the sclerotic, so as to thrust the retina sufficiently forward to receive the image formed by such a lens. (See the subsequent remarks on the eyes of fishes.) Again, instead of the dark-brown or black pigment which lines the human choroid, a pigment of a brilliant metallic lustre is secreted in many of the mammalia, forming the so-called *tupetum lucidum* at the bottom of the eyeball, which seems (according to Bowman) to act as a concave reflector, causing the rays of light to traverse the retina a second time, and thus probably increasing the visual power, particularly where only a feeble light is admitted to the eye. The pupil, moreover, varies in form, being transversely oblong in the Ruminants and many other Herbivora, and vertically oblong in the smaller genera of Cats. These shapes are apparently connected with the positions in which the different animals look for their food. Lastly, in some mammals (e.g. the horse) there is a rudimentary third eyelid corresponding to the *membrana nictitans* of birds.

In birds, the eye, though presenting the same general composition as in man, differs from the mammalian eye in several important points. From our knowledge of the habits of birds (especially birds of prey), we should naturally expect that in their rapid movements they would be able readily to alter the focus between the extremes of long and short sighted vision, and the modifications we shall now proceed to notice clearly have this object in view.

In reference to fig. 8, which represents a section of the eye of the owl, we see (1) that the shape of the organ is not spherical, as in mammals, nor flattened anteriorly, as in fishes and aquatic reptiles, but that the cornea is very prominent, and the antero-posterior diameter lengthened; the consequence of this arrangement being

Fig. 8. — Eye of Bird.

to allow room for a large quantity of aqueous humour, and to increase the distance between the lens and the posterior part of the retina, and thus to produce a greater convergence of the rays of light, by which the animal is enabled to discern near objects. In order to retain this elongated form, we find a series of bony plates, forming a broad zone, extending backwards from the margin of the cornea, and lying imbedded in the sclerotic. The edges of the pieces forming this bony zone overlap each other, and are slightly movable, and hence, when they are compressed by the action of the muscles of the ball, there is protrusion of the aqueous humour and of the cornea, adapting the eye for near vision; while relaxation of the muscles induces a corresponding recession of the humour and flattening of the cornea, and fits the eye for distant vision. The focal distance is further regulated by a highly vascular organ called the *maspium*, or *pecten*, which is lodged in the posterior part of the vitreous humour (fig. 8, *a*). It is attached to the optic nerve at the point where it expands into the retina, and seems to be endowed with a power of dilatation and contraction; as it enlarges, from distension of its blood-vessels, it causes the vitreous humour to push the lens forwards, while, as it collapses, the lens falls backwards again towards the retina.

In addition to an upper and lower eyelid, birds have an elastic fold of conjunctiva, which, in a state of repose, lies in the inner angle of the eye, but is movable by two distinct nictitantes, which draw it over the cornea. It is termed the *membrana nictitans*; it is to a certain degree transparent, for (according to Cuvier) birds sometimes look through it, as, for example, the eagle when looking at the sun. The lachrymal gland is situated as in mammals, but there is here a second gland, the *glandula Harderi*, which yields a lubricating secretion.

There are no very special peculiarities in the eyes of reptiles, and we therefore proceed to notice the most remarkable points presented by the eye in fishes. From the comparatively great density of the medium (water) through which the rays of light pass before they impinge upon the transparent structure of the eye of the fish, it is obvious that this organ must act as a very powerful refractive apparatus. The main peculiarity in the eye of the fish is the size, extreme dens-

Fig. 9. — Eye of Fish.

ity, and spherical shape of the lens, which give it such an extraordinary magnifying power that it has been employed as a simple microscope. See Brewster's *Treatise on the Microscope*, p. 31. But its focus being shortened in proportion as its power is increased, it is necessary that the retina should be brought near its posterior surface. For this purpose the eyeball is flattened by diminishing the quantity of vitreous humour; and this flattened form is maintained by the existence of two cartilaginous plates in the tissue of the sclerotic, which in some of the larger fishes is actually converted into a bony enp. The aqueous humour, as the cornea has here hardly any refractive power and is also flattened, is barely sufficient to allow the free suspension of the iris. The pupil is very large, so as to take in as much light as possible, but is generally motionless. Their eyes being constantly washed by the water in which they live, no lachrymal apparatus is necessary, nor does any exist; and the same remark applies to the *ctacea* amongst the mammals. We thus see that throughout the sub-kingdom of the *vertebrata* the eye is constructed according to one general scheme, with modifications to suit the mode of life of individual classes.

There is another organ present in most vertebrate animals which seems, from recent investigations, to represent an eye, though it is very doubtful whether it has the power of sight in any living animal. This is represented in mammals and birds by the pineal gland (see BRAIN); but in some lizards is placed upon the top of the head, and has the appearance of a rudimentary eye, similar in structure to that of some of the Invertebrata.

In the Invertebrata there is an immense variety in the structure of the eye where such an organ is present. There are two main types, *simple* and *compound* eyes. In *simple* eyes (of which the human eye itself is the most highly organised form), every degree of complexity is present, from a mere pigmented spot, with or without a rudimentary lens, to an organ nearly as complicated as that of the Vertebrata (e.g. in some of the Cuttle-fishes), with a cornea, iris, lens, and retina all well

developed. In these eyes, however, almost without exception, the nerve expands behind the retina, and the percipient elements are directed towards the light; while in the vertebrate eye the opposite arrangement obtains.

Some of these organs are so rudimentary that they can have no function beyond mere perception of light; but in cases where they are sufficiently developed to admit of the perception of objects, they see, roughly speaking, as our eyes do—that is to say, a more or less accurate picture of external objects is thrown on the expansion of nerve-endings corresponding to the retina, and its direction is reversed (see below).

In the *compound* eyes the whole principle of the structure and perception is different. They are best developed in Insects (q.v.), and in the higher Crustaceans; but occur in a rudimentary condition in some molluscs. The surface of such an eye is divided into a number of hexagonal facets, the cuticle of each generally forming a minute lens. Beneath each facet is a transparent rod, surrounded and separated from those adjacent to it by pigment, and leading inwards to the retinula, a group of cells in connection with the terminal fibrils of the optic nerve. In most familiar insects they form two hemispherical masses on the sides of the head. In some ants there are only fifty facets in each eye; in the house-fly about 4000; in some beetles as many as 25,000. It is probable that in these eyes only the rays of light which fall upon a particular facet exactly, or very nearly, in the direction of the transparent rod beneath it can reach the corresponding nerve-fibre, and that other rays are absorbed by the pigment around the rod. Each percipient element therefore receives light only from a very small portion of the field of vision, and the picture is a mosaic, each element of which is furnished by a different facet of the eye. The picture has obviously the same position as the objects it represents, instead of being inverted as in a simple eye. Most insects have simple as well as compound eyes; but the latter have by far the most perfect vision.

(3) We may now proceed to the consideration of the uses of the various parts of the eye. Assuming a general knowledge of the ordinary laws of geometrical optics (see OPTICS, LENS, &c.), we shall trace the course of the rays of light proceeding from any luminous body through the different media on which they impinge. If a luminous object, as, for example, a lighted candle, be placed in front of the eye, some of its rays fall upon the cornea, and are in part reflected, giving to the surface of the eye its beautiful glistening appearance; in part refracted or converged by it, to enter the aqueous humour, which exerts no perceptible effect on their direction. Those which fall on and pass through the outer or circumferential part of the cornea are stopped by the iris, and are either scattered or absorbed by it; while those which fall upon its more central part pass through the pupil, and are concerned in vision. In consequence of its refractive power, the rays passing through a somewhat larger surface of the cornea than the pupil are converged so as to pass through it and impinge upon the lens, which, as its refractive index is much greater than that of the aqueous and vitreous humours, by the convexity of both its surfaces very much increases the convergence of the rays passing through it. They then traverse the vitreous humour, whose principal use appears to be to afford support to the expanded retina, and are brought to a focus upon that tunic, forming there, if the eye be adjusted for the distance from which the rays proceed, an exact but inverted image of the object.

This inversion of the image may be easily exhibited in the eye of a white rabbit or other albino animal, after removing the muscles, &c. from the

back part of the globe. The flame of a candle (A, B, C, fig. 10) held before the cornea may be seen inverted at the back of the eye (*a*, *b*, *c*), increasing in size as the candle is brought near, diminishing as it retires, and always moving in a direction opposite to that of the flame.

Fig. 10.

The adjustment of the eye for distinct vision at different distances, or *accommodation*, must next be considered. The normal eye in the position of rest is adjusted to see objects at a distance (practically all objects at 20 feet or more are seen with equal clearness): to see a near object (at 10 inches, say) a distinct effort is required, and when the effort ceases the object at once appears blurred. Careful observations and measurements by means of a suitable instrument (Ophthalmometer) of images reflected from the three principal refracting surfaces of the eye (cornea, anterior and posterior surfaces of crystalline lens) have shown that during

Fig. 11.—Action of Ciliary Muscle and Iris in accommodation:

A, (right or left) half; eye at rest, or focused for a distant object. B, (left or right) half; eye focused for a near object. *a*, cornea; *b*, sclerotic; *c*, anterior part of choroid; *d*, ciliary muscle; *e*, suspensory ligament of lens; *f*, anterior capsule of lens; *g*, iris.

accommodation for a near object (1) the position and curvature of the cornea remains unchanged; (2) the anterior surface of the crystalline lens approaches the cornea and becomes much more convex; (3) the posterior surface does not change its position, but becomes very slightly more concave. Accommodation, then, depends upon change of shape of the crystalline lens. The true explanation of the mechanism by which this is effected was first given by Helmholtz. The ciliary muscle, as already stated, has its fixed attachment all round within the sclerotic close to the margin of the cornea; and passes outwards and backwards to the anterior part of the choroid, close to the ciliary processes. When it contracts, therefore, it draws these structures inward; and with them the outer attachment of the suspensory ligament of the lens. The tension of this membrane is thus relaxed, and the elastic lens, whose form as well as position is controlled by it, is allowed to assume a more spherical shape. When the ciliary muscle ceases to contract, the converse takes place, and the lens is again flattened as the suspensory ligament and lens capsule become more tense. With the contraction of the ciliary muscle is always associated a contraction of the circular fibres of the iris, diminishing the size of the pupil; and when the ciliary muscle relaxes, the pupil enlarges again. This

change, though of much less importance than the change in shape of the lens, is much more easy to observe.

Change of adjustment requires a short but measurable time; that from distant to near vision requires a little longer time than the converse; the former from a little over one to two seconds, the latter about one second.

As age advances, the power of accommodation steadily and quickly diminishes, not because the ciliary muscle gets weaker, but because the lens becomes less elastic. This change begins during youth, but is not commonly noticed before middle life. At ten years of age an object can be seen distinctly at less than 3 inches; at twenty, not nearer than 4 inches; at about forty-five, not nearer than 10 inches; at sixty, not nearer than 3 feet. After seventy-five, the lens is so unyielding that accommodation is altogether lost. When the shortest distance at which distinct vision is possible approaches that at which reading or work is usually attempted, the failure of accommodation begins to attract attention, and spectacles have to be resorted to to compensate for it. This condition has received the name of *presbyopia* or old sight, but must be clearly understood to be perfectly natural after the age of forty-five, and in no way to imply defect or weakness of the eyes.

The eye, regarded as an optical instrument, has numerous imperfections: the more important of these must be mentioned.

*Spherical aberration* (see LENS) is in part avoided by the iris, which, acting as a diaphragm, cuts off all but the central pencil of rays; in part by the forms of the refracting surfaces, which are not truly spherical, but ellipsoidal or hyperbolic — i.e. more curved at the centre than elsewhere; in part by the constitution of the lens (see above). What remains is, like *chromatic aberration*, for which no correction seems to exist, too slight to be perceptible.

Regular *astigmatism* (q.v.) is present in almost all eyes, but is generally so small in amount as to be of no importance.

*Imperfect Transparency of Media.*—The stellate arrangement of the lamellæ of the lens is the cause of the rayed (or, as we say, star-shaped) appearance of a point of light. *Musca volitans*, the clear threads or strings of beads often seen in looking at a bright surface flitting about when the eye is moved, are due to the shadows of the minute fibres and corpuscles naturally present in the vitreous humor.

(4) We must now consider how the image formed in the back of the eye by the dioptric media gives rise to vision. It is the retina, and only that part of it known as the layer of rods and cones (see fig. 5), which is directly affected by light.

Let two marks be made on a sheet of paper about 3 inches apart horizontally (a cross and a round mark to the right of it). Close the left eye, and holding the paper about a foot from the face, look steadily at the cross; the circle is also visible. Now bring the paper gradually nearer, keeping the right eye fixed upon the cross. The circle soon disappears; but becomes visible again when the paper is brought still nearer the eye. The *blind spot* in which the circle becomes invisible is the entrance of the optic nerve; hence we know that the nerve-fibres themselves are not sensitive to light. Further proof of this is given by *Purkinje's figure*, which is easily perceived as follows: Take a candle in a room otherwise dark, and holding it a short distance in front and to the outer side of one eye, move it from side to side, looking straight forward. A set of branching dark lines, the shadows of the retinal blood-vessels, will be seen (see fig. 4). These could not be perceived unless the sensitive

portion of the retina lay behind the blood-vessels, which the nerve-fibre layer of the retina does not.

Stimulation of the retina, however it may be caused, gives rise to the sensation of light. Thus, slight pressure on one side of the eyeball causes an appearance of flashes of light towards the opposite side. A sudden blow on the eye, or the indirect shock to it of a fall on the head, makes one 'see stars.' Electric currents passed through the eye similarly cause a sensation of bright light. But true vision is only caused by rays of light falling upon the retina.

In what way light affects the layer of rods and cones we do not know. Probably it produces some chemical change, which leads to stimulation of the nervous elements. A substance called *visual purple* or *rhodopsin* has been found in the outer segments of the rods of some mammals, which is bleached on exposure to light, and restored in darkness. Photographic pictures of bright objects have even been obtained in eyes of rabbits, &c. by means of it. But as it is absent in the most sensitive portion of the human retina, it cannot be the chief factor in the production of vision.

The *fovea centralis* (see fig. 1) is the part of the retina where vision is most acute: as cones only are present here, it is clear that they are more delicately adjusted for their function than the rods, which greatly preponderate at other parts of the retina. When the eye looks straight at an object (or in technical language *fixes it*), its image falls upon this part of the retina. In *direct* vision, as this is called, two black marks on a white ground are distinguished as separate when the interval between them subtends an angle of about one minute at the eye. It is found by calculation that this angle, prolonged to the back of the eye, pretty nearly corresponds to the distance between two adjacent cones at the fovea centralis. The vision at other parts of the retina (*indirect vision*) is very much less acute, and less capable of accurate measurement. We have only to fix steadily one letter in a page of ordinary print to satisfy ourselves in how small an area we can see sufficiently distinctly to make out words without moving the eyes. The *field of vision*, or whole space within which objects are perceived by an eye while it is fixed upon one point, is very much wider, extending in each eye to more than 90 degrees from the fixation point or centre to the outer side, and rather less in other directions. Colour-vision is also most distinct at the centre of the field; and it is found that it diminishes more rapidly towards the outer portions than light-vision, so that near the limits of the field colours cannot be recognised.

There must be a certain amount of light for the purpose of vision. Every one knows that it is difficult and painful to discern objects in a very faint light; and, on the other hand, that on suddenly entering a brilliantly lighted room from the dark, everything appears confused for one or two seconds. There is, however, a gradual adaptation of the retina to different amounts of light. Persons long immured in dark dungeons acquire the power of distinctly seeing surrounding objects; while those who suddenly encounter a strong light are unable to see distinctly until the shock which the retina has experienced has subsided, and the iris has duly contracted. In protecting the retina from the sudden effects of too strong a light, the iris is assisted by the eyelids, the orbicular muscle, and to a certain extent by the eyebrows. Moreover, the dark pigment of the choroid coat acts as a permanent guard to the retina, and where it is deficient, as in albinos, an ordinary light becomes painful, and the protective appendages, especially the eyelids, are in constant use.

The persistence during a certain time of impressions made on the retina facilitates the exercise of sight. Such persistent impressions are called *after-images*. A momentary impression of moderate intensity continues for a fraction of a second; but if the impression be made for a considerable time, or be very intense, it endures for a longer period after the removal of the object. Thus, a burning stick, moved rapidly in a circle before the eyes, gives the appearance of a continuous ribbon of light, because the impression made by it at any one point of its course remains on the retina until it again reaches that point. It is owing to this property that the rapid and involuntary act of winking does not interfere with the continuous vision of surrounding objects; and, to give another illustration of its use, if we did not possess it, the act of reading would be a far more difficult performance than it now is, for we should require to keep the eye fixed on each word for a longer period, otherwise the mind would fail fully to perceive it. However great may be the velocity of a luminous body, it can always be seen; but if an opaque body move with such rapidity as to pass through a space equal to its own diameter in a less time than that of the duration of the retinal impression, it is altogether invisible; and hence it is, for example, that we cannot see bullets, &c. in the rapid part of their flight. In these cases the after-image is of similar brightness and colour to the original impression, and is known as a *positive* after-image. When the stimulation of the retina is very strong, or the retina itself in a very sensitive condition—e.g. in certain morbid states of the system and in twilight, a *negative* after-image appears, in which the bright parts of the original impression appear dark and *vice versa*. An image of this kind may persist for some seconds or minutes or even longer. This physiological phenomenon has probably given origin to many stories of ghosts and visions. Thus, if a person has unconsciously fixed his eyes, especially in the dusk, on a dark post or stump of a tree, he may, on looking towards the gray sky, see projected there a gigantic white image of the object, which may readily be mistaken for a supernatural appearance. The phenomenon is easily seen on looking away from a bright window after directing the eyes to it for some time, when the bars appear as bright lines on a dark ground. Negative after-images are always of the complementary colour to that of the object. Thus, the image left by a red spot is green; by a violet spot, yellow; and by a blue spot, orange.

(5) Each eye can be moved from its ordinary position, looking straight forward, through an angle of nearly 60 degrees downwards, and of 35 to 45 degrees in other directions. But one eye never moves without the other. Two series of associated movements have to be distinguished: movements of both eyes in the same direction, and movements which *converge* the eyes, or bring the corneæ of both eyes towards each other. When a near object is looked at, the movement of accommodation is associated with a proportionate contraction of the internal recti of both eyes, so as to direct the visual axis, or in other words the fovea centralis, of each towards the object.

If we suppose the retinæ of the two eyes to be placed in contact, so that the foveæ centrales and the vertical meridians correspond, then all points which lie together in the two retinæ are called *corresponding points*, and have the property that simultaneous stimulation of both gives rise only to a single impression. An object whose image falls upon corresponding points thus appears single; otherwise it appears double. Hold up two

fingers in line in front of the face. When the nearer one is looked at, it is seen single, but the farther appears double and somewhat out of focus; when the farther is looked at, it appears single, and the nearer is similarly doubled and blurred. Generally speaking, images of the great majority of the objects in the field of vision of both eyes must fall on non-corresponding points of the two retinæ; but as the attention is generally directed to the images of the object for which the eyes are accommodated, and as these, falling upon the foveæ centrales, are much the most distinct, the double vision of other objects is seldom noticed.

In the case of near objects, however, something more is needed to explain single vision. For example, take the case of a solid object. The two eyes, looking from different points of view, receive quite different images; the right eye sees more of the right side, the left eye more of the left. It is impossible that the images of each point of the object can fall upon accurately corresponding points of the two retinæ. Yet the appearance presented is that of a single object clearly defined. In this case then there must be in the brain-centres a power of combining in a single picture images which do not accurately correspond.

Various topics which the reader might perhaps have expected to find noticed, such, for instance, as 'the appreciation of solid forms by the sense of vision,' 'correct vision with an inverted image on the retina,' &c., which belong fully as much to metaphysics as to physiology, are discussed in the article on VISION. We may also refer those who desire information on these points to Professor Bain's treatise on *The Senses and the Intellect*.

For the anatomy of the eye, see Quain or other standard work. Lubbock in *The Senses of Animals* gives a concise account of the chief types of eyes in the Invertebrata. Helmholtz's *Physiological Optics* is the classical work on the optical aspects of the eye. The larger works on human physiology—e.g. Foster, Landois and Stirling—may also be consulted.

DISEASES AND INJURIES OF THE EYE, as might be expected from the delicate and complicated structure of the organ, are very numerous. But as the position of the eye and the transparency of its dioptric media give exceptional facilities for their detection and study, they are more thoroughly understood than those of any other organ. Only the most common and important can be referred to here.

*Diseases of Conjunctiva* are mainly different forms of inflammation, or *conjunctivitis*.

(a) *Simple or Catarrhal Conjunctivitis* may be acute or chronic. In the former case, it is commonly called 'cold in the eye.' The white of the eye is more or less reddened, and there is an increased discharge of gummy substance, causing the lids to cohere during sleep; a sensation is experienced as of sand or dust in the eyes, and there is a little increased sensitiveness to light. The acute form generally subsides in a few days without leaving any ill effects, unless improperly treated; the chronic form is often obstinate. The common popular treatment—viz. tying wet cloths or poultices over the eye, cannot be too strongly condemned; it may produce temporary relief of irritation, but aggravates the inflammation, and is very apt to lead to ulceration of the cornea. A mild astringent lotion should be used thrice or oftener in the day (cold tea; boracic acid 10 grains, alum 3 grains, to the ounce of water); and a little simple ointment or fresh butter applied to the lids at bedtime to prevent their becoming glued together. The chronic form often requires stronger remedies, but they should not be used except under medical advice.

(b) *Purulent Conjunctivitis* resembles the last, but is very much more severe, and highly dangerous. In its most characteristic forms it is known as *gonorrhoeal ophthalmia*, and *ophthalmia neonatorum* (eye inflammation of new-born children). To the latter variety about one-third of the blind persons in Europe owe their loss of sight. It is produced by inoculation of the eye with certain irritating discharges; and the discharge from an affected eye will infect any other eye with which it comes in contact. The conjunctiva becomes intensely red and swollen, and the lids partake in the swelling so that they cannot be opened; there is severe burning pain, and after two days or more a profuse discharge of matter. The danger to sight is due to the fact that the cornea is extremely apt to be destroyed, wholly or in part, before the inflammation subsides. In infants the disease usually begins on the third day after birth, and is, as a rule, less severe than in the adult, but unfortunately is often overlooked, or regarded as of no importance till irreparable mischief has been done. Scrupulous cleansing of the eyes immediately after birth, preferably with corrosive sublimate lotion (1 grain to 8 ounces) is the best preventive. When the disease has commenced, very frequent removal of discharge and hourly washing with boracic or corrosive sublimate lotion should be resorted to. But all such cases should at once be put under the charge of a medical man.

(c) *Pustular or Phlyctenular Conjunctivitis* is a form of inflammation very frequent in children, much less so in adults. It is an indication of a lowered state of the general health, and its treatment must include fresh air and light, good food, and cod-liver oil or some other strengthening medicine. The inflammation does not extend all over the white of the eye, but is localised in one or more sections of it, and is most intense near the margin of the cornea, where one or more small rounded blebs or pimples may be seen. It is often accompanied in children by extreme tenderness to light; but the tendency to this is aggravated by a bandage or darkness. The local treatment should be bathing with boracic acid or some other mild astringent lotion; but, unless the case be very mild, a medical man should be consulted.

(d) *Granular Conjunctivitis*, or *trachoma*, is an exceedingly chronic and intractable disease. It is sometimes called *Egyptian ophthalmia*, having been extremely prevalent in the French army in Egypt in 1798. In Europe it is most common among the Jews and the Irish, but is often troublesome in industrial schools and similar institutions. It is encouraged by overcrowding, bad ventilation, and other unfavourable hygienic conditions, and is undoubtedly somewhat contagious. It is characterised by numerous distinct semi-transparent elevations on the conjunctiva of the lids, chiefly the upper. It often lasts for months or years, and is chiefly dangerous on account of the shrinking of the conjunctiva produced by it, which leads to trichiasis, Ectropion (q.v.), and opacity of the cornea. It should always be treated by a skilled medical man.

(e) In *Diphtheritic Conjunctivitis* there is a 'false membrane' formed on the conjunctiva, as in Diphtheria (q.v.) in other situations. It is happily rare in Britain.

*Diseases of the Cornea.*—The most common and important are inflammations associated with ulceration—i.e. destruction of some of the corneal substance. This is replaced when healing takes place by imperfectly transparent tissue, and results very frequently in great impairment of vision (irregular Astigmatism, q.v.), even where no obvious mark remains. The appearances, symptoms, and appro-

priate treatment of different forms and stages of corneal ulceration are extremely various, and cannot profitably be discussed here. Skilled medical advice should always be obtained. It must suffice to say that the eyes should be rested, shaded from light, and bathed, generally with boracic or corrosive sublimate lotion. Puncturing or tying up the eyes should never be resorted to unless under a doctor's orders, as it is usually still more mischievous than in conjunctivitis.

In one form of inflammation of the cornea, called *interstitial*, there is an appearance all over it of great haziness or even complete opacity, but without breach of surface. It occurs usually in boyhood or girlhood, and though alarming in appearance and tedious, generally results in complete recovery. Mr Jonathan Hutchinson first pointed out that it is usually a manifestation of congenital syphilis.

The *sclerotic* is comparatively seldom affected by disease, probably on account of its slight vascularity and comparatively low vitality.

The *iris* is liable to inflammation (*iritis*), characterised by severe deep-seated pain, redness of the white of the eye, contracted pupil, and much dimness of sight. The inflammation, if unchecked, produces adhesion between the posterior surface of the iris and the anterior capsule of the lens, which may permanently interfere with vision, or even lead ultimately to complete loss of sight. Local treatment at the early stage by Atropia (q.v.) dilates the pupil and prevents the formation of adhesions. Unless the result of injury, *iritis* usually depends on constitutional causes, especially syphilis and rheumatism, and treatment of these is of prime importance for its cure. Medical aid should be sought at once; for atropia, which is most beneficial in *iritis*, is disastrous in glaucoma, a disease which sometimes resembles it in many of its symptoms.

The chief disease of the *lens* is opacity, or Cataract (q.v.); it may also be displaced or dislocated, either from an anomaly in its development, or as the result of injury.

Diseases of the deeper structures of the eye (choroid, vitreous humour, retina and optic nerve) usually require for their recognition the use of the Ophthalmoscope (q.v.). Generally speaking, they are associated with little or no pain, and attract the patient's attention in consequence of the dimness of vision they produce. They are much less amenable to treatment in most cases than affections of the more superficial parts.

Inflammation and atrophy of the *choroid* occur in several forms; the most distinct are those occurring in syphilis, in old age, and in connection with high degrees of short-sightedness (progressive myopia, see below).

The *vitreous humour* rarely if ever becomes diseased, except in consequence of changes in the ciliary body or choroid. The abnormal condition generally manifests itself in more or less opaque threads or films, which move with the movements of the eye, and appear to the patient as clouds or dark lines interfering with vision, much more large and distinct than the 'muscae volitantes' present in the normal eye.

The *retina* may be the seat of hemorrhage or of inflammation in many forms of disease. The most common and characteristic retinitis is that associated with Bright's disease (q.v.), which is almost always of very serious import. Its main artery may become blocked by a plug carried into it from the heart or elsewhere (*Embolism*; see ARTERIES, DISEASES OF), an accident which causes sudden and usually almost complete loss of sight. Not unfrequently, too, the retina becomes detached from the choroid, either as the result of disease or injury, and floats in the

vitreous chamber in front of its normal position, a condition greatly interfering with sight, and most difficult to improve.

The optic nerve may become inflamed (*optic neuritis*), most commonly in consequence of an inflammation or tumour of the brain or its membranes. It may degenerate (*optic atrophy*) either after inflammation or independently of it. In the latter case, however, as well as the former, there is in the great majority of instances some disease of other parts of the nervous system (brain or spinal cord).

There are two diseases chiefly affecting the deeper parts of the eye which it is desirable to describe at some length, as their course is often insidious, and their results when not recognised early, most disastrous, while timely interference is often signally successful in preserving the sight. These are *glaucoma* and *sympathetic ophthalmia*.

*Glaucoma* occurs most commonly during or after middle life, frequently in persons whose eyes are hypermetropic (see below). It may come on with such suddenness and intensity that vision is lost in a few hours, or its course may extend over years. Always, however, if unchecked, it tends to progress till sight is destroyed. Both eyes are usually affected, but often one long before the other. In many cases there are *premonitory* symptoms, consisting in temporary attacks of cloudiness of vision, during which the patient, when looking at a light (e.g. a gas or candle flame), sees it surrounded by coloured rings or halos. During this 'premonitory stage,' the vision is perfectly normal between the attacks; but they become more frequent and prolonged, till it is permanently impaired. Variability of the symptoms is usually a characteristic feature in all stages of the disease. Often in the later phases, and always in acute and severe cases,

the eye the the cornea more or less hazy; and some of the blood-vessels of the white of the eye larger and more visible than they should be. The most important sign of the disease, and the feature on which many of its characteristics depend, is increased hardness of the eyeball, owing to increase of its contents. The exact cause of this increased hardness is not fully understood, nor the way in which some of the symptoms observed depend upon it; but it varies with the symptoms, being always more marked when the pain and dimness are at their worst. Chronic insidious cases are often mistaken for cataract, though the use of the ophthalmoscope readily distinguishes between the two conditions; in the most acute cases, the headache, sickness, and general disturbance of the system is sometimes so severe that the condition of the eyes is overlooked, and the disease is looked upon as a 'bilious attack' till the vision is hopelessly destroyed.

The disease was regarded as absolutely hopeless till Von Graefe, in 1857, proved that the removal by operation of a portion of the iris of a glaucomatous eye might arrest the process. This proceeding (*iridectomy*), though by no means uniformly successful, does good in the majority of cases, and has been of enormous benefit. But if too long delayed, it is of no avail for the restoration of vision.

It is of great importance that atropin or belladonna should not be applied to an eye with any tendency to glaucoma, as they aggravate the disease, and sometimes even produce it. Eserin, the active principle of the Calabar bean, has an action on the eye antagonistic to atropin, and can often keep glaucoma in check, though it rarely cures it. Pilocarpin, the active principle of *Jaborandi*, has a similar action.

*Sympathetic Ophthalmia* is the name given to a form of inflammation, chiefly of the iris and ciliary body, occurring in an eye previously healthy in consequence of disease or injury of the other. Almost, if not quite, invariably the eye first affected has had its coats (cornea or sclerotic) perforated; and the process in the second eye may begin at any time, from a fortnight to many years after this occurrence. It is an extremely insidious disease, sometimes quite painless; but also extremely dangerous, for it often leads to total loss of sight. The early symptoms are watering, tenderness to light, and dimness of sight, especially of near objects. When it begins, there is almost invariably irritability and tenderness to touch in the eye which is the origin of the disease. It can be absolutely prevented by early removal of the eye first affected; but if this be delayed till the inflammation has begun in the second eye, it may be useless. An eye which has received a perforating wound, particularly in the 'ciliary region'—i.e. just outside the cornea—may therefore at any subsequent period become a source of danger to the other eye; and if its vision is destroyed there can be no doubt that it should be removed. Even if some useful sight is retained, this may sometimes be desirable; but at all events, every one who has suffered from such an injury to one eye should know that the slightest symptoms of irritation or failure of sight in the other should at once lead him to seek skilled advice. Recent researches have rendered it probable that this form of inflammation is caused by micro-organisms, though this is not quite definitely established.

*Errors of refraction* are those defects in the dioptric media of the eye which, without diminishing their transparency, interfere with the formation of a retinal image in the normal way. Astigmatism (q.v.) has already been noticed; presbyopia is the failure of accommodation natural to age (see above). It remains to describe *myopia*, or short-sightedness, and *hypermetropia*, or long-sightedness. In most cases the condition of both eyes is alike, or nearly so; but exceptionally there is a considerable difference between them (*anisometropia*).

The knowledge of this branch of the subject was first systematised and placed on a satisfactory basis by Donders (1818-89), a distinguished Dutch physician and physiologist, professor of Physiology at Utrecht, in his work on *Anomalies of Accommodation and Refraction of the Eye* (Eng. trans. pub. by Sydenham Society, 1866).

The normal eye in the position of rest is adjusted for parallel rays—i.e. for a distant object, and by means of the accommodation can be focused for a near object. The short-sighted eye at rest is adjusted for divergent rays—i.e. for a near object; accommodation enables it to focus for a still nearer object, but it can make no change enabling it to see clearly beyond its 'far point'—i.e. that for which it is adjusted at rest. The long-sighted eye at

Fig. 12.

A, Normal eye: parallel rays brought to a focus at retina. B, Hypermetropic eye: globe shortened; parallel rays not yet brought to a focus when they reach retina. C, Myopic eye: globe lengthened; parallel rays brought to a focus in front of retina.

rest is adjusted for convergent rays, which do not occur in nature; accommodation enables it to focus parallel rays (from distant objects), or divergent rays (from near objects), but not to see so near as a normal eye of the same age.

These defects generally depend on an abnormality in the length of the antero-posterior diameter of the eyeball; in short-sighted eyes it is greater, in long-sighted less than the normal (see fig. 12). They can be corrected by the use of suitable glasses; in short-sighted eyes concave lenses are used, which render the rays of light falling upon them more divergent; in long-sighted eyes convex lenses, which render the rays less divergent or convergent.

Loss of accommodation occurs with the progress of years in such eyes, just as in normal ones, though the effects are somewhat different. The short-sighted eye continues to be able to see near at hand without spectacles; but, contrary to the popular belief, has no other advantage over the normal eye as age advances, for vision of distant objects does not improve. The long-sighted eye in time loses the power of seeing even distant objects without spectacles; and the higher the degree of long-sightedness the earlier the age at which this occurs.

An abnormal shape of the eye, on which these 'errors of refraction' usually depend, is frequently hereditary, and is incurable; it usually remains stationary after early adult life, but in some cases of myopia, where it is associated with disease of the choroid, tends to become worse (*progressive* or *malignant myopia*). The object of treatment must be to counteract, so far as possible, the inconvenience resulting; and this can generally be done by the use of spectacles or eyeglasses. No general rules can be laid down as to their use, as much depends not only on the degree of the abnormality, but on the age and occupation of the individual. If glasses conduce to comfort and to the preservation of the sight, no mere regard for appearance should prevent their being worn.

*Diseases of the Eyelids.*—A *stye* is practically a minute Boil (q.v.) formed in the eyelid, and discharging at its margin. It should be fomented frequently with hot water till it bursts. Constitutional treatment is often desirable, as styes often occur, like boils, in groups or series.

Small rounded swellings (*tarsal cysts*) often form under the skin of the lids, owing to obstruction of the duct of a Meibomian gland. They are usually painless, but require for their cure the evacuation of their contents through a puncture on the inner surface of the lid.

A form of Eczema (q.v.) often occurs at the margin of the lids, called *blepharitis*, most commonly in delicate children. It can usually be readily cured if attended to in time; but if neglected, as it too often is, leads to destruction (blind eyes) or misdirection (trichiasis) of the eyelashes, and much subsequent trouble. It is characterised by redness and ulceration of the edges of the lids, usually masked by crusts adhering to the lashes. Frequent removal of these, with the daily application of a stimulant ointment (e.g. yellow oxide of mercury, 8 grains to the ounce of simple ointment), and the use of tonics generally effect a cure. Inversion (Entropion, q.v.) and eversion (Ectropion, q.v.) of the margins of the lids, and misdirection of the eyelashes (trichiasis), so that they rub against and irritate the cornea, are troublesome affections, usually requiring operation for their removal.

*Diseases of the Lachrymal Apparatus.*—A 'watery eye' (*epiphora*), when no irritating affection of the eye itself is present, usually proceeds from stricture of the nasal duct, or some other cause, which prevents the tears from discharging by their natural channel into the nose. The condition can be remedied in most cases by slitting up the canalic-

ulus (see fig. 7), and passing graduated probes through the duct to restore its patency. If unattended to, it generally leads sooner or later to abscess of the lachrymal sac, with much swelling and pain.

*Injuries.*—In no part of the body is there so often great disproportion between the severity of an injury and the amount of pain and irritation it occasions. A penetrating wound sometimes causes less discomfort than a mere particle of sand beneath the eyelid. Any wound or blow affecting the eye, therefore, particularly if it interfere at all with the sight, should be seen by a doctor as speedily as possible. Substances thrown against the eye may injure it. Quicklime is rapidly destructive to the eye, slaked lime and mortar less so. When one of these, or any other alkaline caustic, has got into the eye, diluted vinegar should at once be used to neutralise it. If it is oil of vitriol (sulphuric acid) or another acid that has been the cause of the injury, a weak solution of soda may be used in the first place to neutralise the acid. After this, sweet oil is the best thing to introduce, until the surgeon arrives. In gunpowder explosions near the eye, besides the burn, the particles are driven into the surface of it, and will cause permanent bluish stains over the white of the eye, unless they are carefully removed at the time. When chips of glass, stone, &c. are driven into the interior of the eye, there is little hope of its being saved from destructive inflammation, though fragments of iron and steel are sometimes removed by means of a strong electromagnet, with a successful result. In these and all other *penetrating wounds*—i.e. those where the cornea or sclerotic is broken through, the possibility of subsequent sympathetic ophthalmia in the other eye must be borne in mind. When only partially sunk into the cornea, as is often the case with sparks of cinder or iron, &c., or 'sires,' as they are called, the rubbing of the projecting part on the eyelid causes great pain, and the surgeon has not much difficulty in removing them. Most commonly these, or other 'foreign bodies,' as particles of dust, sand, seeds, flies, &c., when not speedily washed away by the tears, merely get into the space between the eyeball and the lids, almost always concealed under the upper, as it is the larger, and sweeps the eye. They cause great pain, from the sensitiveness of the papillary surface of the lid, and of the cornea over which they are rubbed by its movements, soon excite inflammation, and their presence, as the cause, is apt to be overlooked. The lid must be turned round to find them. To do this, pull the front or edge of the lid forward by the eyelashes, held with the finger and thumb, and at the same time press down the back part of the lid with a small pencil or key, directing the patient to look downwards. The lid will readily turn round, when the body may be seen about its middle, and may be removed with the corner of a handkerchief. Another plan, which the person himself may try, is to pull forward the upper lid by the eyelashes, and push the lashes of the lower lid up behind it, when the foreign body may be brushed out. After the bodies are removed, a feeling as if they were still there may remain for some time. See BLIND, COLOUR-BLINDNESS.

*ARTIFICIAL EYES* are worn for the sake of appearance in cases where, as the result of disease or injury, an eye has either been totally lost, or rendered unsightly. They are, moreover, distinctly advantageous in cases where a gaping socket is liable to irritation by dust, cold winds, &c. They cannot be used unless the size and prominence of the eyeball is at least somewhat diminished. Few surgeons in Britain recommend them to be worn unless the eyeball is either entirely removed (enucleation), or has the front part removed

(abscission), or all the contents extracted (evisceration); for the artificial eye is apt to cause irritation of the sensitive anterior portion of the globe, and may lead to the development of sympathetic ophthalmia (see p. 515). Enucleation is the most certain means of preventing this; but the other operations named above allow of better movement, and give a more natural appearance to the eye.

An artificial eye consists of a thin shell, usually of enamelled glass, coloured to present as nearly as possible the same appearance as the visible part of the normal eye. Quite recently Celluloid (q.v.) has been used instead of glass, and is said to last better, as its surface is not affected by the secretions; while it has the advantages that it is not brittle, and can easily be pared to fit the socket accurately. To obtain a satisfactory result, it is necessary either to have the eye specially made, or to be able to select from a very large stock; as colour of iris, size of pupil, tinge of sclerotic, as well as curvature of surface and form of margin, must be adapted to the particular case. They are therefore to be got to most advantage in large cities, such as London or Paris.

The eye must not be worn continuously, but removed each night and replaced in the morning. It is slipped in under the lids, which hold it in position. Even when the globe has been entirely removed, the muscles, by their attachment to the tissues remaining in the orbit, usually effect movements in the same direction, though not of the same extent, as those of the normal eye; and it is often difficult for any but a practised observer to detect to what the difference between the two is due. A single glass eye can rarely be worn more than a year without being polished, for the surface becomes roughened by the action of the tears, &c., and irritates the lids as they rub over it. The wearing of a glass eye therefore means an expenditure of at least one or two pounds a year, and is thus out of the power of many poor people to whom it would otherwise be an advantage.

Common Eyebright  
(*Euphrasia officinalis*).

**Eyebright** (*Euphrasia*), a genus of Scrophulariaceae. The British species (*E. officinalis*) is a root-parasite common in pastures and grassy uplands, which at the end of summer are gowned abundantly with its bright little flowers. From this general aspect and spotted corolla the popular name is derived; hence, too, the doctrine of signatures ascribed it an efficacy in the treatment of eye-diseases, which a mild astringency long aided it to maintain. It is the *Euphrasy* of Milton.

**Eylau**, a town of 3546 inhabitants, 23 miles S. of Königsberg by rail. Here Napoleon encountered the allies—Russians and Prussians—under Bennisgen, February 8, 1807. Darkness came on while the contest was still undecided; but as Napoleon had a considerable force of fresh troops close at hand, the allies retired during the night upon Königsberg. Their loss is estimated at about 20,000; that of the French is set down at 10,000, but must have been considerably greater. The place is called Preussisch-Eylau, to distinguish it from Deutsch-Eylau, a town of 4574 inhabitants, 89 miles NE. of Bromberg.

**Eyot** (A.S. *igoth*), a little island in a river, especially one overgrown with willows, as in the Thames.

**Eyre**, EDWARD JOHN, an Australian explorer and colonial governor, the son of a Yorkshire clergyman, was born in August 1815. Emigrating to Australia at the age of seventeen, he prospered as a squatter on the Lower Murray, and was appointed a resident magistrate and protector of the aborigines. In 1840 he failed in an attempt to explore the region between South and Western Australia, though he discovered Lake Torrens. The task which he had set himself, however, he accomplished, in spite of enormous difficulties, in 1841 (*Discoveries in Central Australia*, 1845). In 1846 he became lieutenant-governor of New Zealand, and in 1852 of St Vincent in the West Indies. In 1862 he was appointed governor of Jamaica, where in 1865 negro disturbances broke out. The outbreak was suppressed with sharp, stern severity, martial law being proclaimed in the disaffected district; a wealthy mulatto named Gordon, a Baptist and member of the Jamaica House of Assembly, who had taken a leading part in instigating the rising, was hurriedly tried by court-martial, and hanged two days after, the sentence having been confirmed by Eyre. A commission sent to inquire into this case found that Gordon had been condemned on insufficient evidence, and Eyre was recalled. On his return he was prosecuted by a committee of whom John Stuart Mill was the most prominent; Thomas Carlyle, Charles Kingsley, and Sir R. Murchison promoted the Eyre defence fund. The prosecutions could not, however, be sustained; and eventually in 1872 the government refunded to Eyre the costs of his defence. Since his recall he has lived in retirement.

**Eyre**, LAKE, a salt lake of South Australia, lying due N. of Spencer Gulf, at an altitude of 79 feet, and with an area of 3706 sq. m. Except in the season of rains, this lake is generally a mere salt marsh. It was discovered in 1840 by Eyre.

**Eyre**, JUSTICES IN. See ASSIZE.

**Eyria Peninsula**, on the south coast of South Australia, triangular in shape, its base being formed by the Gawler Range, whilst its sides are washed on the SE. by Spencer Gulf, and on the SW. by the Great Australian Bight. It constitutes a rich pastoral country.

**Ezekiel** (meaning 'God will strengthen,' or 'strength of God'), one of the Hebrew prophets, was the son of the priest Buzi, and along with Jehoiachin, king of Judah, was carried captive, when still a young man, to Mesopotamia, by order of Nebuchadnezzar, about 599 B.C. He was a member of the Jewish community which settled on the banks of the river Chelar, and first appeared as a prophet about the year 594, after the remarkable vision described in his opening chapters. His prophetic career extended over a period of twenty-two years. The date of his death is not recorded. —The Book of Ezekiel consists of three great parts, dating respectively from before, during, and after the siege of Jerusalem: the *first* (chapters i.–xxiv.), composed before the final conquest of Jerusalem by Nebuchadnezzar, announces the complete overthrow of the kingdom of Judah, on account of its increasing unfaithfulness to God, and especially its perjury in forming an alliance with Egypt after accepting vassalage under Babylon; the *second* (chapters xxv.–xxxii.) threatens the seven surrounding nations, which were exulting maliciously over the ruin of Judah, with divine punishment; and the *third* (chapters xxxiii.–xlvi.) prophesies the future deliverance of the Hebrew nation, the rebuilding of Jerusalem, and the vision of the temple and its measurement, a symbol of the

restored theocracy. This last portion contains certain predictions, usually interpreted as directly Messianic, the future deliverer being conceived under the form of 'David, the Good Shepherd' (xxxiv. 23; xxxvii. 24), who shall reign gloriously over Israel. The book is full of magnificent but artificial symbolism, and of allegories difficult to understand; whence St Jerome calls it 'a labyrinth of the mystics of God,' and the Jews themselves placed it among 'the Treasures'—not to be read before the age of thirty. Some passages, as the first and second chapters, reveal a vivid and sublime imagination. The authorship of the book has not been seriously assailed, although the Talmud asserts that it was written by the Great Synagogue, of which Ezekiel was not a member; and Zunz dated it about the year 400 B.C. Keil and Knenck make Ezekiel both its author and editor; Ewald detects obvious traces of later elaboration, and suggests that the collection and combination of the various prophecies into a book may not have been the prophet's own doing. Graf believed Ezekiel also the author of part of Leviticus (chaps. xviii.—xxiii., xxv., xxvi.), and has been followed by many supporters. 'Ezekiel,' according to Wellhausen, 'is the connecting link between the prophets and the Law. He claims to be a prophet, and starts from prophetic ideas; but they are not his own ideas—they are those of his predecessors, which he turns into dogmas. He is by nature a priest, and his peculiar merit is that he inclosed the soul of prophecy in the body of a community which was not political, but founded on the temple and the cultus. . . . Thus arose that artificial product, the sacred constitution of Judaism.' The text of Ezekiel is far from being in a perfect condition. It is partly corrupted by glosses, has partly been retouched by later hands, and may often be amended by the Septuagint version. A splendid example of Hebrew scholarship is the Hebrew text reconstructed from the Septuagint by Dr Carl Heinrich Cornill (Leip. 1886). See Duhm, *Die Theologie der Propheten* (1875); and the commentaries by Havernick (1843), Hitzig (1847; 2d ed. by Smend, 1880), Fairbairn (1851), Kliefoth (1864 *et seq.*), Hengstenberg (2 vols. 1867 *et seq.*), Keil (1868; 2d ed. 1882), Schröder (1873); and Ewald, *Die Propheten des Alten Bundes* (2d ed. 1868).

**Ezra** ('help,' Gr. and Lat. form *Esdras*), the Scribe, the descendant of the high-priest Seraiah (who was put to death after the destruction of Jerusalem by Nebuchadnezzar), first becomes known to us as living with the Jewish exiles in Babylon during the reign of Artaxerxes Longimanus. With this king he stood so high in favour that he was commissioned to lead a band of his fellow-countrymen from Babylon to Jerusalem (458 B.C.), there to reorganise the Jews, the descendants of those who returned in the reign of Cyrus, and to teach them the Law. By the same decree the priests, Levites, and temple servants generally were exempted from all taxation. Ezra's first care, after his arrival at Jerusalem, with the Law of God in his hand (vii. 14), was to annul the marriages that the Jews had contracted with the women of the surrounding nations. After this nothing more is heard of him for thirteen years. In 445 Nehemiah

came to Judæa as Persian governor. He quickly delivered the struggling community from external pressure, and set all things in order for the work of Ezra. At a great public meeting convened by Nehemiah (Neh. viii.—x.) the Law was solemnly read in the ears of the people; and this was followed by a second renunciation of their foreign wives on the part of those who in the interval had lapsed into their old habits, by the institution of the feast of tabernacles—which had not been observed according to the Law since the days of Joshua (Neh. viii. 17)—by a solemn pledge to keep Sabbaths and holy days and to duly observe the Sabbatical year, and by the promulgation of ordinances whereby the expenses connected with the temple and its services might be defrayed. It was a solemn national covenant subscribed by the secular and spiritual leaders, eighty-five in number, and the rest of the people 'clave unto their brethren, their nobles, and entered into a curse, and into an oath, to walk in God's Law.' After this we read no more of Ezra the scribe.

It was probably during the interval between his first and his second appearance that Ezra arranged in one collection the books of the Mosaic law (the Pentateuch) as we have it now. The book which bears his name was anciently and justly regarded as forming one book with Nehemiah; and in their present shape Ezra and Nehemiah are simply the continuation of Chronicles (q.v.). The Book of Ezra consists of two portions. Chapters i.—vi. inclusive narrate the story of the first band of exiles who returned to Jerusalem in the reign of Cyrus about the year 538; the remainder (chapters vii.—x. inclusive) relates the events attendant upon Ezra's leadership of the second band of returning Jewish exiles. Not all of this book is written in Hebrew: iv. 8 to vi. 18 are written in Aramaic, the *lingua franca* of the Semitic world at that epoch of history. The work of Ezra began the transition from the religion of the living Word to the written letter. His services in fixing the text of the Law led in later times to the legend that he had restored from direct inspiration not only the Pentateuch (supposed to have been burned in the destruction of Jerusalem), but all the rest of the Old Testament, and other holy books besides; and they also formed the foundation of the equally fabulous legend of the 'Great Synagogue.' He had humbly distinguished himself from the prophets (ix. 11), and though the greatest man in the later spiritual history of Israel, he was no prophet in the true sense, but a priest and scribe, whose whole heart was set on the sacred ordinances, as set down in the 'book of Moses' written by God's servants the prophets. Yet in later times he was even identified with the prophet Malachi (Targum to Mal. i. 1), and Mohammed, in the 9th Surâ of the Koran, speaks of Jews of his time who in opposition to the Christians held Ezra to be the Son of God. See BIBLE, ESDRAS, and the commentaries by Bertheau (1862), Keil (1870; Eng. trans. 1873), F. W. Schmitz (1876), and Neteler (1877), and the introductions by Rosenzweig (1876) and Sayce (2d ed. 1887); also Robertson Smith, *The Old Testament in the Jewish Church* (1881), and Wellhausen, *Prolegomena to the History of Israel* (Eng. trans. 1885).

is the sixth letter in the English and Latin alphabets. The original symbol in the Egyptian hieroglyphs was the picture of a cerastes or horned asp; the horns being represented by the two horizontal bars in our F, and the body by the vertical stroke (see ALPHABET). When the Egyptian sign was adopted by the Phœnicians it received the name of *Vau*, from the resemblance to a nail or peg. From the Phœnicians it passed into the early Greek alphabet as a semi-vowel, but at some time previous to the oldest extant Greek inscriptions it was differentiated into two characters, one of which, F, had the sound of *w*, and the other, V, with the name *upsilon*, became a vowel. As early as the 7th century B.C. the character F became obsolete as a letter in the Eastern Greek alphabet, being retained only as the numeral for six (see DIGAMMA). It must, however, as Bentley proved, have been in use when the earlier portions of the Homeric poems were written. In the Western alphabet, which was used chiefly in the Peloponnesus, F was retained as a letter till the 5th century B.C. From the Chalcidian alphabet it was transmitted to Italy, retaining its position as the sixth letter, but acquiring in Latin the sound of *f* instead of *v* or *w*.

This sound *f* is called a labio-dental fricative, and is formed by bringing the lower lip into contact with the upper teeth. Hence it is one of the easiest of the consonants to pronounce, and may take the place, under certain circumstances, of any of the mutes. Thus, a primitive *bh*, *gh*, and *dh*, which respectively become *b*, *g*, *d* in English, may be represented by *f* in Latin. For instance, the Sanskrit *bhar* corresponds to the English *bear* and the Latin *fero*; while the Sanskrit *bhratar* is the English *brother* and the Latin *frater*. The Sanskrit *dhuma* corresponds to the Greek *thumos* and the Latin *fumus*; the Sanskrit *dvāra* to the Greek *thura*, the Latin *fores*, and the English *door*; the Greek *thēr* to the Latin *fera* and the English *deer*. The Greek *cholē* is the English *gall* and the Latin *fel*. Other correspondences are exhibited in the Latin *fremo*, which answers to the Greek *bremo*; and in *frango*, where the *f* answers to the aspirate in the Greek *rhēgnumi*. An *f* easily lapses into *h*, as is seen in the Italic equivalences *faba* and *haba*, *fircus* and *hircus*. So the Spanish *hembra* represents the Latin *femina*. An English *f* usually represents a primitive *p*, as is seen by comparing *father* with *pater*, *fish* with *piscis*, or *foot* with *pes*. In *four* and *five* the English *f* corresponds to a guttural in the Latin *quatuor* and *quinque*. The words *enough*, *cough*, and *laugh*, in which *gh* is pronounced as *f*, exemplify the tendency of gutturals to lapse into the easier sound. The Russians regularly change the difficult sound of *th* into *f*, the name *Theodore*, for instance, becoming *Feodor*. In like manner children sometimes say *free* and *fum* for *three* and *thumb*.

An Anglo-Saxon *f* is sometimes lost in modern English. Thus, *hlafofd*, *hafoc*, *wif-man*, and *hus-*

*wife* have become *lord*, *hawk*, *woman*, and *hussy*. Or *f* may become *v*, as in *vixen*, which is merely the feminine of *fox*.

The Greek letter *phi* was not equivalent in sound to the Latin *f*, but was rather a *p* followed by an aspiration, as in our word *up-hill*. Thus, though a primitive *bh* becomes *phi* in Greek and *f* in Latin, the Romans, when transliterating Greek names, were careful to represent *phi* by *ph* and not by *f*, and this distinction is very properly followed in English when we write *Philip* and *phonetic*, instead of *Filip* or *fonetic*. From erroneous analogy, *ph* is sometimes used in words not derived from the Greek, as in the case of *Adolphus*, which represents the Teutonic *Adolf*, and is correctly written *Adolfe* by the French.

F, in Music, is the fourth note of the natural diatonic scale of C. See MUSIC, SCALE, KEY.

**Faam**, or FAHAM (*Angræcum fragrans*), an orchid, native of Madagascar, &c., prized for the fragrance of its leaves, which is owing to the presence of *Commurin* (q.v.), and resembles that of the Tonka Bean and of Vernal Grass. In Mauritius an infusion of faam leaves is in great repute as a cure for pulmonary consumption and as a stomachic. It has also been imported into France as Isle of Bourbon Tea (*folia faham*), and used in infusion and as a source of perfume.

**Fabaceæ**. See LEGUMINOSÆ.

**Faber, CECILIA**. See CABALLERO, FERNAN.

**Faber, FREDERICK WILLIAM**, hymn-writer, was born at the Yorkshire vicarage of Calverley, 28th June 1814, passed from Shrewsbury School to Harrow, and thence to Balliol College, Oxford, and in 1834 was elected a scholar of University College. He carried off the 'Newdigate' in 1836 with his poem, 'The Knights of St John,' graduated with a second class the same year, and was elected to a fellowship in University College the year after. Already he had come under the potent spell of Newman, and in November 1845, after three years' tenure of the rectory of Elton in Huntingdonshire, he followed his master into the fold of Rome. He next founded a community of converts at Birmingham as Brothers of the Will of God, but called commonly Wilfridians, as he himself was Brother Wilfrid, from his *Life of St Wilfrid*, published in 1844. Together with his companions he joined in 1848 the Oratory of St Philip Neri, and next year a branch under his care was established in London, which was finally located at Brompton in 1854. He was created D.D. by Pius IX. in 1854, and died at the Brompton Oratory, 26th September 1863. Faber wrote many theological works, stamped by profound learning and lightened by unusual grace of style. But his lasting fame will rest upon his hymns, which have warmed the piety of thousands of English-speaking Christians beyond their writer's own communion. 'The Pilgrims of the Night,' and 'The Land beyond the Sea,' have been among the most popular hymns of the 19th century. A complete collection, containing 150 hymns, was published in 1862. See the Lives by J. E. Bowden (1869), and his brother, F. A. Faber (1869).

**Faber**, GEORGE STANLEY, Anglican divine, was the eldest son of the Rev. Thomas Faber, and was born at Calverley vicarage, near Bradford, 25th October 1773. He entered University College, Oxford, in 1789, and four years later was elected Fellow and Tutor of Lincoln College. As Bampton Lecturer for 1801, he delivered the lectures subsequently published under the title of *Horæ Mosaicæ* (1801). In 1805 he became vicar of Stockton-on-Tees, and, after several changes, received in 1832 the mastership of Sherburn Hospital, near Durham. He died at Sherburn on 27th January 1854. Of Faber's numerous theological works, those upon prophecy have enjoyed the greatest popularity. All his writings are marked by 'strong masculine sense, extensive classical erudition, and a love of hypothesis.'

**Faber**, JOHN (1684-1756). See ENGRAVING, p. 381.

**Fabius**, the name of one of the oldest and most illustrious patrician families of Rome. Three brothers of this name successively held the office of consul during the seven years 485-479 B.C. In 481 the Fabii were decoyed into an ambuscade near Rome by the Veientes, with whom they had been at war, and, with the exception of one member (through whom the race was perpetuated), the entire *gens*, consisting of 306 men, was put to the sword. The most eminent of the *gens* were QUINTUS FABIVS RULLIANUS and QUINTUS FABIVS MAXIMUS VERRUCOSUS. The former was the most eminent of the Roman generals in the second Samnite war, and was dictator (315), censor (304), and six times consul. The latter, who was five times consul and twice censor, was elected dictator (221) immediately after the defeat of the Romans at Trasimenum. The peculiar line of tactics which he observed in the second Punic war obtained for him the surname of Cunctator ('Delayer'). Hanging on the heights like a thunder-cloud, to which Hannibal himself compared him, and avoiding a direct engagement, he tantalised the enemy by the favourite devices of guerilla warfare; he harassed them by marches and counter-marches, and cut off their stragglers and foragers; and at the same time his delay allowed Rome to assemble her forces in greater strength. But this 'Fabian policy' was neither appreciated in the camp nor at home; and shortly afterwards, Marcus Minucius Rufus, Master of the Horse, was raised to an equal share in the dictatorship. During his fifth consulship Fabius recovered Tarentum (209 B.C.), which had long been one of Hannibal's important strongholds. He died in 203 B.C.—CUNCTATOR FABIVS, surnamed Pictor, executed in 302 upon the walls of the temple of Salus the earliest Roman painting of which we have any record. His grandson, QUINTUS FABIVS PICTOR, was the first writer of a Roman history in prose.

**Fable**, as defined by Dr Johnson in his *Life of Gay*, is, 'in its genuine state, a narrative in which beings irrational, and sometimes inanimate—*arbores loquuntur, non tantum feræ*—are, for the purpose of moral instruction, feigned to act and speak with human interests and passions.' It is thus almost synonymous with the apologue, and closely allied to the allegory and the parable, but it need not be at all probable in its incidents, its essential motive being more a moral or didactic end effected by any means, while its composition is due to more or less conscious literary art. In earlier times the name was frequently used as synonymous with myth, but this sense was dropped when a deeper insight into the mental condition of primitive man had revealed how small a factor conscious fiction was in the making of so composite a product as the mythology of a people. It is usual again to differentiate

the parable from the fable as especially conveying spiritual truths, and not transgressing possibility and the actual order of nature; but, leaving out of sight the special examples in the New Testament, it is impossible to make so sharp a distinction between moral and religious truths. In the earlier stages of the history of every people the human intellect has employed itself in rudimentary metaphysical speculations, and hence a host of myths have arisen everywhere of themselves to account for natural phenomena, the origin of man, and the like, which in many cases have been preserved. These myths are of course quite innocent of moral, and, indeed, in the hopeless confusion of a composite mythology, are usually strangely inconsistent with considerations of morality, being survivals of an irrational state of mind to which they seemed natural enough. Side by side with this process in the mind of many peoples, a rudimentary literary faculty early began to exercise itself, giving rise to real fables. One large class, indeed the most important, whether from the point of view of quality or of quantity, takes the form of fables about beasts, with whom primitive man has no difficulty in feeling a sense of affinity. These again develop with progressive culture and a growing moral sense into the didactic apologue, and thus reach the class of fables proper, as being essentially due to conscious literary art. These, unlike the myths that have grown spontaneously as an attempt to find concrete expression for those ideas and impressions about the relations between man and the physical world that lie at the basis of religion, lend themselves early to transmutation, and have actually, as we shall see, travelled round the world. The folklore of even the rudest people contains many complex elements, but it is only as culture begins to advance that we find the beginning of the literary fable proper, although it remains true that a large number of the folk-tales are more or less perfect fables. While this is true, it is no less so that it is merely in half-civilised communities that the fable attains its greatest perfection. We find the moral apologues so dear to the oriental mind ranging in a thousand forms, from the scriptural example of Jotham to the elaborate and involved examples in the *Arabian Nights*.

The old French *Fabliaux* have little in common with fables beyond a name of similar origin, being short tales in verse, essentially satirical, or rather representing human things under the light of a ludicrous or only half-serious mockery. Of the genuine fables of medieval times the greater number were associated with the name of *Æsop*, whom it is usual for classical scholars to place in the 6th century B.C. Certainly his name occurs frequently in classical literature as that of a fabulist, but the so-called *Æsopic* fables that have come down to us are far from being Greek in character, to any great extent at least. The collection formed by Planudes of Constantinople in the first half of the 14th century has much in common with the metrical Greek fables of Babrius, who lived most likely in the 1st century B.C., and again with the Latin fables of Phædrus, a freedman of Augustus, because the ultimate source of many fables of these and other fabulists was the same—the Buddhist birth-stories and other Indian tales, which had long before been gradually finding their way westwards through Arab or still more obscure channels. Many of our Greek fables are substantially identical with the Buddhist *Jātakas*, and can be explained on no theory but that of simple transmission, often within even historical times. This much at least is certain, that a considerable part of the *Æsopic* fable reached the Greeks from the East, however obscure our knowledge of the methods of transmission may yet be. The medieval examples of the fable follow

closely the two Latin versions (1) of Avianus, comprising fables in distichs, rendered at a later period into prose, and almost all borrowed from the immediate Greek originals bearing the name of Æsop; and (2) to a still greater extent a prose version of the fables of Phædrus, represented in the prologue as a translation into Latin of the Greek fables of Æsop by a certain Emperor Romulus for his son Tiberinus. The Latin *Romulus* was enlarged about the 11th century by a number of fables of quite a different character, bearing in the highest degree the stamp of the middle ages, and often of Christianity (as in that of the wolf who learns to read), coming in great part from India, by way of Byzantium, most frequently badly told, usually very obscure, but often original, well invented, and of a very popular character, as in that of the cat that has put on a stole in order to baptise a rat which wishes to remain a Pagan. The collection as thus increased originated without doubt in England, and at an early date was rendered in English, and associated without reason with the name of Alfred. It was from this lost English version that it was translated, in the reign of Henry II., by Marie de France, into elegant but somewhat dry French verses. She gave her work the name of *Isopet*, the title of all medieval collections of fables, itself really a mere familiar diminutive of the name of Æsop, to whom all apologues were always attributed. About the same time an author whose name is unknown rendered into Latin distichs the first three books of *Romulus*, comprising fifty-eight fables, to which he added two stories, one from an unknown source, the other borrowed from the *Disciplina Clericalis* of Petrus Alphonsus, a converted Jew, whose work—a book of moral instruction, filled with stories of Arab (and ultimately Indian) origin—must have been put together about the close of the 12th century. According to custom, this collection of fables was connected with the name of Æsop; its pretentious style brought it great success, and we have extant two verse translations of the 13th and 14th centuries, the *Isopet de Lyons* and the *Isopet II. de Paris*—the last called also the *Isopet-Avonnet*, because the translation of Æsop therein follows that of Avianus. Another redaction, by Alexander Neckam (12th century), in Latin distichs, was twice translated into verse in the *Isopet de Chartres* and the *Isopet I. de Paris*. Of these translations the most interesting, because the freest, is the *Isopet de Lyons*; all alike abound in misconstructions, to which the obscure language of their models lent itself too easily, and from which the rhymers extricate themselves as best they can.

Besides these special collections of fables, the best and most original examples, whether in French or Latin, are often to be found in the works of the moralists, the preachers, and even the historians, as, for example, in the *Récits du Ménestrel de Reims* (1260), a collection of semi-popular and current hearsay traditions, having for its point of departure the first Crusade, and loosely connected with the Holy Land, France, England, and Flanders. From the 12th century there were often inserted in sermons *Exempla*, or short tales, sometimes edifying in themselves, sometimes having the character of parables or even merry stories, from which the preacher at the end extorted a moral. These were stories merely Christianised for the ends of edification, and were very frequently nothing more or less than time-honoured fables. The collection in French by the English Franciscan Nicole Bozon (13th century) is particularly rich in such fables told in a lively and popular manner. Side by side with these fables transmitted by the clergy there circulated among the people many beast-fables, which, like the primitive examples of African and other savage peoples, are destitute of any moral aim, but unlike

these are due to conscious literary art in depending mainly upon a sympathetic and humorous observation of certain animals, whose adventures conform to their supposed character and their known habits. A great many of these stories have for their theme the struggles between the wolf, the stronger, and the fox, the more cunning, which ends always in the former being worsted. The great innovation which developed out of these a kind of beast-epic was the individualising of the heroes and giving to them proper names; the figures with which we are concerned are no longer a wolf and a fox, but Isengrim and Raganhard, with their wives Richild and Hersind (later Isengrin, Renard, Richent, Hersent). Around these principal personages the action centres, and beside them we find a crowd of secondary actors: Noble the lion, Grimbert the badger, Belin the ram, Chanteclair the cock, Conard the hare, Tibert the cat, and Bernard the ass, who throughout preserve their characters and play consistent parts. This ingenious and artistic transformation may have originated in the north of France about the 11th century, but quickly spread over western Europe in Latin, German, and Flemish versions, and, both from the intrinsic interest of the theme, and its adaptability to satirical purposes, as well as its admirable artistic treatment, exercised a powerful influence over the popular imagination from the dark ages to the age of Goethe.

The prime fable of medieval times followed closely its venerable originals, as we find them still in our *Panchatantra*, *Hitopadesa*, and *Kalilah wa Dimnah*; but our modern examples have little beyond what is external in common with these, for the fable has long ceased to be a natural form for literary expression in prose or verse. The fables of Prior, Moore, and Gay are lively and often graceful poems, but they have usurped a name to which they really possess no claim. Nor are Dryden's so-called *Fables* fables at all, however effective as poems they may be. Quite different is the case of the great master of fabulists, the inimitable La Fontaine, who possessed one merit rarer even than his exquisite blending of humour and pathos and his matchless perfection of form, in that 'infantine familiar clasp of things divine' in which lies hid the real essence of the fable. No successor has discovered the secret of that exquisite naïveté on which depends his charm, although the imitators of this new form in literature have been countless in number. Gellert's German fables (1746) were among the most popular of these, and first attracted the great Lessing into imitation. The latter published his famous *Fabeln* in 1759, together with a striking essay on the history and meaning of the fable in literature, the conclusions of which were mostly much more subtle than always sound. Of more recent fables the best are a few examples among the exquisite prose fairy-tales of Hans Christian Andersen and the examples in verse of the Russian Krilof: everywhere else the making of fables would appear to be an art that is lost without hope of recovery.

See the articles *ÆSOP*, *BEAST-FABLES*, *BIDPAI*, *FABLIAUX*, *FOLKLORE*, *MYTHOLOGY*, and *REYNARD*; also Max Müller's essay 'On the Migration of Fables,' in vol. iv. (1880) of *Chips from a German Workshop*; W. G. Rutherford's dissertation on 'The History of Greek Fable,' in his edition of *Babrius* (1883), which is good so far as it goes; but especially O. Keller's 'Untersuchungen über die Geschichte der Griechischen Fabel,' in the *Jahrbücher für classische Philologie* (1861-67); Leopold Hervieux, *Les Fabulistes Latins depuis le Siècle d'Auguste jusqu'à la fin du Moyen Age* (2 vols. 1884); and the admirable chapter by Gaston Paris, in *La Littérature Française au Moyen Age* (1888).

**Fabliaux**, a group of over a hundred compositions peculiar to the literature of France, consisting of metrical tales, usually satirical in quality, written

in octosyllabic couplets, the epoch of the production of which covers about a century and a half. The oldest preserved appears to be *Richent* (about 1156); the greater number belong to the end of the 12th and the commencement of the 13th century; the most modern are those of Jean de Condé and of Watrquet, at the beginning of the 14th century. Society and literature then underwent a considerable change, and henceforward fabliaux proper disappear, being represented during the 15th century on one side by the prose tale, on the other by the farce, whence sprung in the fullness of time the modern novel and the comedy. Many of the French rhymed stories of the 12th and 13th centuries reappear later in the literature of other peoples, chiefly in Italy and England. It is certain that Boccaccio and Chaucer, for example, have sometimes imitated the French fabliaux, but this need not have been necessarily the case, as these stories circulated freely orally over all Europe, not to speak of their admission into sermons and books of edification.

Undoubtedly most of the stories were of oriental and especially Indian origin, many bearing distinctly the imprint of Buddhism, which has ever favoured the method of teaching by parable. These stories reached Europe by two main channels: from Byzantium, which received them from Syria or from Persia, whence they had been carried direct from India; and secondly, from the Arabs. The Arab importation took place at two widely different points: in Spain, largely by the mediation of the Jews; and in Syria, at the time of the Crusades. In Spain the transmission was mainly literary (through such media as the *Disciplina Clericalis*); in the East, on the contrary, the Crusaders, who lived in intimate contact with the Mussulman population, received many stories orally. Some of these being of Buddhist origin were already moral and ascetic in character, and therefore easily Christianised; others, under cover of the final moral, related adventures that were dubious enough, but which were remembered while the tedious and not always relevant moral was forgotten; while others again were retained and transmitted simply for their wit. The fabliaux were, however, without exception, strangers to those great collections transmitted entire from one language to another; they spring from oral transmission and not from books. A few even are due to the native invention of their authors.

Their most general characteristic is their humorous and comic quality, too often involved in obscenity, and not infrequently falling into the most rapid platitude. Many of them are satirical, girding especially at certain classes, as villeins and clerics, who are made the heroes of amorous adventures, now happy, now unhappy. A few are concerned with religion, and these are incongruous and irreverent enough. The fabliaux were not written for women, no doubt being usually recited by the *jongleurs* when the women had left the room; hence women are usually presented in the most unfavourable colours, whether as abandoned in character, or merely as peevish and jealous. They abound in gross sallies, the aim of which was but a moment's laugh; yet many are sweet little stories, very well told, and usually very moral or very sentimental. All have the great merit of painting the real life of their time; not at all of set purpose, but without effort they enable us to penetrate into the hearths of nobles, clergy, citizens, or peasants, and they speak to us in the familiar tongue of diverse classes of society in France about seven centuries ago. Their authors are seldom known. One or two names are Huon le Roi, author of *Vain Palefroi*; Jean Bedel, author of *Barat et Hainet*; Gautier le

Long; Jacques de Baisieu; Henri d'Andeli; Rusteuf; Garin; Jean le Galois d'Aubepierre, author of *La Bourse pleine de sens*; and Jean de Condé.

All the fabliaux are printed by A. de Montaiglon and G. Raynaud in their great *Recueil général et complet des Fabliaux des XIII<sup>e</sup> et XIV<sup>e</sup> Siècles* (Paris, 6 vols, 1872-90). See also Gaston Paris, *Les Contes orientaux dans la Littérature Française du Moyen Âge* (Paris, 1877), and pp. 110-116 of *La Littérature Française au Moyen Âge* (Paris, 1888); also Landau, *Die Quellen des Dekameron* (2d ed. Stutt. 1884).

**Fabretti**, RAFFAELE, Italian antiquary and archaeologist, was born at Urbino in 1618. Although he devoted himself to law, he was also attracted at an early period to antiquarian studies by the classical remains of Rome. Under Pope Alexander VII. he became papal treasurer, and subsequently was appointed chancellor to the papal embassy at Madrid. After a residence of thirteen years in Spain he accompanied the legate Bonelli to Rome, where shortly afterwards he became keeper of the papal archives of the castle of St Angelo. His principal works, *De Aquis et Aqueductibus Veteris Romæ* (4 vols. 1680, reprinted with notes and additions in 1688), *Syntagma de Columnis Trajani* (Rome, 1683), works on the aqueducts of Rome and the column of Trajan, preceded his *Inscriptionum Antiquarum Explicatio* (1690). His collection of inscriptions, &c. is deposited in the ducal palace of Urbino. Fabretti died at Rome in 1700.

**Fabriano**, a city of Italy, at the eastern base of the Apennines, 44 miles by rail S.W. of Ancona. It has a cathedral and the Rossenti museum, but is chiefly noteworthy for its paper and parchment manufactories, established in 1564. The churches and private houses contain many specimens of the Fabriano school of painting. Pop. 5593.

**Fabrizio**, GENTILE DA, an Italian painter, was born at Fabriano about 1348. His first teacher in art was, according to one account, Allegretto de Nuzio, according to another, Fra Angelico. His earliest work was perhaps the decoration of a chapel for Pandolfo Malatesta at Brescia. In 1423 he painted one of his best extant pictures, an 'Adoration of the Kings,' for the church of the Holy Trinity in Florence. To the same period belongs a Madonna with Saints (now in the Berlin Museum). A picture of the naval engagement between the fleet of Venice and that of the Emperor Barbarossa, which Fabrizio painted for the Venetian senate, so pleased them that they conferred on him the dignity of a patrician and a pension of a ducat *per diem* for life. This picture perished in the fire which destroyed the ducal palace in 1574. Fabrizio next worked at Orvieto, but was called thence by Pope Martin V., who employed him in adorning the church of St John Lateran with frescoes from the life of John the Baptist. He died at Rome about the year 1428. Fabrizio's pictures indicate a cheerful and joyous nature. He had a childlike love of splendour and rich ornamentation, but his colouring is never extravagant or meretricious. See an article by W. F. Stillman in the *Century* for July 1889.

**Fabricius**, or FABRIZIO, GIROLAMO, commonly called of Aequapendente, from the place of his birth, near Orvieto, a celebrated anatomist and surgeon, was born in 1537. He was the son of humble parents, who notwithstanding their poverty sent him to the university of Padua, where he studied anatomy and surgery under Fallopius. On the death of the latter in 1562 Fabricius was appointed to the vacant professorship, a post which he continued to hold for nearly half a century. Harvey, the discoverer of the circulation of the blood, was one of his pupils. Fabricius died at Padua, 21st May 1619. He was a laborious

investigator of nature, studying the structures of animals by the comparative method. In this way he treated the eye, the larynx, the ear, the intestinal canal, the development of the foetus, and many other subjects. His chief contribution to anatomy was, however, the discovery of the valves of the veins in 1574. His *Opera Chirurgica* (1617), which embraced every complaint curable by manual operation, passed through seventeen editions. Albinus published a complete edition of his anatomical and physiological works (Leyden, 1738).

**Fabricius, JOHANNES CHRISTIAN**, one of the founders of scientific entomology, was born at Tondern, in Sleswick, January 7, 1745, and died at Kiel, 3d March 1808. After studying at various universities he went to Upsala to work under Linnæus, whose ideas and methods he made his own. In 1775 he was appointed to the chair of Natural History at Kiel, and from that time he devoted himself to the development of his system of classification of insects, based upon the structure of the mouth. His views are expounded in his *Systema Entomologicæ* (1775), *Genera Insectorum* (1776), *Philosophia Entomologica* (1778), *Mantissa Insectorum* (1787), and *Entomologia Systematica* (1792). A complete list of his entomological writings is given in Hagen's *Bibliotheca Entomologica*, and an account of his life in *Trans. Entomol. Soc.*, vol. iv. (London, 1845).

**Fabroni, ANGELO**, biographical writer, was born at Marradi, in Tuscany, 25th September 1732, educated at Faenza and Rome, and in 1773 appointed tutor to the sons of Leopold, Grand-duke of Tuscany. He died 22d September 1803. His *Vita Itulorum Doctrina Excellentium* (20 vols. 1778-1805) contains quite a treasure of information; while his *Laurentii Medicei Vita* (2 vols. 1784) and *Vita Magni Cosmi Medicei* (2 vols. 1788-89) were reckoned model biographies.

**Fabulous Animals.** See **BESTIARY**, **GRIF-FIN**, **UNICORN**, &c.

**Fabyan, ROBERT**, an English chronicler under Henry VII., was descended from an Essex family, and followed his father's trade as a clothier in London, where he was sheriff in 1493, and seems to have died in 1513. Three years later was printed by Pynson the first edition of his history, *The New Chronicles of England and France*. It begins with the arrival of Brutus, and comes down to the battle of Bosworth, reaching in its second edition (1533) the death of Henry VII. From the accession of Richard I. it takes the form of a London chronicle, and indeed the whole work has little value save for some points in the history of the city. The best edition is that by Ellis (1811).

**Façade** (Fr.), the exterior front or face of a building. This term, although frequently restricted to classic architecture, may be applied to the front elevation of a building in any style. It is, however, generally used with reference to buildings of some magnitude and pretensions; thus, we speak of the *front* of a house, and the *façade* of a palace. The back elevation of an important building is called the rear *façade*, and a side elevation the lateral *façade*. The sides of a court or cortile are also called *façades*, and are distinguished as north, south, &c. *façades*.

**Facciolati, JACOPO**, lexicographer, was born in 1682 at Torreglia, near Padua, and educated in the religious seminary at Padua, where he subsequently became professor of Theology and rector. He held at the same time the chair of Logic in the university. Facciolati directed his attention chiefly to the revival of the study of ancient literature, and brought out (1715-19) a new edition of the *Lexicon Undecim Linguarum* or the *Calepine*

*Lexicon*. In this work he was assisted by his pupil and brother-professor, EGDIO FORCELLINI (1688-1768), to whom is mainly owing the conception of a totally new Latin dictionary. This Facciolati continued till his death on 27th August 1769, and it finally appeared in 1771 (new ed. by De Vit, Prato, 1858-87; Eng. ed. 2 vols. 1826). Facciolati's Latin epistles and orations are remarkable for the Ciceronian purity and elegance of their style, and his remarks on Cicero's writings for their solidity, clearness, and taste. See *Lives* by Ferrari (1799) and Gennari (1818).

**Facial Angle.** See **SKULL**.

**Facility**, in the legal terminology of Scotland, is a condition of mental weakness short of idioey, but such as makes a person easily imposed upon, and easily persuaded to do deeds to his own prejudice. The remedy is Interdiction, which may be granted by the Court of Session of its own motion, or at the instance of the heir or next of kin of the facile person. This is judicial interdiction. When a person conscious of mental infirmity places himself under the control of trustees, the case is one of voluntary interdiction. This interdiction generally takes the form of a bond granted by the facile person to the persons therein named, who are called the interdictors. The object of interdiction is to prevent the facile person from granting deeds to his own prejudice, and after it has taken place he cannot contract without the consent of his interdictors. Even without interdiction the deeds of a facile person, if to his prejudice, may be set aside if there be proof of his having been circumvented or imposed on. There is no corresponding term in English law.

**Fac-simile** (Lat. *factum simile*, 'made like'), an exact copy, as of handwriting. See **COPYING**.

**Factor**, in its most general sense, is the term applied to any one who is employed to do business for another. In its most frequent use the name is applied to an Agent (q.v.) employed to sell goods consigned to him by his principal. His remuneration is called factorage or commission, and such an agent a commission-agent or consignee. A broker is also an agent of this kind, rewarded by a commission; but a factor differs from a broker in this, that a factor may buy and sell in his own name, and has the possession and apparent ownership of the goods consigned, and a lien over them. A factor is not entitled to delegate his powers, although he may employ a third person in any ministerial capacity which he cannot himself fulfil. The duty of a factor is to procure intelligence of the markets at his residence, of the course of exchange, and of the price of goods and the probability of a rise or fall; and to account to his principal for his transactions. A factor may pledge the goods of his principal for advances made upon the principal's account, or for the duties on the goods, but not for advances made upon the factor's account. The Factors Acts, the earliest of which was passed in the reign of George IV., enact that under certain circumstances factors having goods in their possession, or having possession of bills of lading, dock warrants, and similar documents referring to goods, shall be deemed owners of such goods, to the effect of giving validity to contracts with persons dealing *bona fide* on the faith of that ownership. Factory may be revoked, and falls by the death of the principal. The appointment of a new factor to do the same act implies revocation of the old factory. These general principles are common to both English and Scotch law. In Scotland, however, there are special uses of the term factor not known to English practice. There the term is applied to an agent managing heritable

estates for another, letting farms, drawing rents, and the like, in which sense it is nearly synonymous with the English *steward*. In Scotland, too, the class of factors appointed by the courts for the management of the estates of persons under some incapacity, where the English courts appoint receivers or trustees, has increased so largely in recent times as to call into existence a whole department of law dealing with their powers and duties. Such are called Judicial Factors.

**Factor**, in Mathematics. The numbers 6 and 4 multiplied together *make* 24; hence 6 and 4 are called *factors* of the product 24. All numbers except prime numbers are products of two or more factors; thus,  $10 = 2 \times 5$ ;  $12 = 3 \times 4$ , or  $2 \times 6$ , or  $2 \times 2 \times 3$ . Every product can be divided by any of its factors without remainder; a factor, therefore, is often called a *divisor*, or measure. 2, 3, 4, 6, 8, 12 are all factors or divisors of 24. Numbers that have no factor or divisor above unity, such as 2, 3, 5, 7, 11, . . . 23, &c., are called *prime* numbers. See NUMBERS (THEORY OF).

**Factory Acts.** The development of the textile industries in Great Britain towards the end of the 18th century led to the employment of a great many children, sent by the poor-law authorities from the southern agricultural counties to the water-abounding districts of Derbyshire, Nottinghamshire, and Lancashire. These children were so ill looked after, and the mills generally so overcrowded, that a Board of Health appointed in 1796 attributed the prevalence of epidemic fevers about Manchester to this cause. The subject was taken up by the elder Sir Robert Peel, who in 1802 passed the *Morals and Health Act*. The introduction of steam led to the *Cotton Mills Act* of 1819, which fixed the working age of children at nine, and the working week for them at 72 hours. The Saturday half-holiday did not come until Sir John Hobhouse's *Act* of 1825. Richard Oastler, the 'Factory King,' was now spreading through the woollen districts of Yorkshire the agitation for the Ten Hours Bill. The *Cotton Industry Act* of 1831 may be called the first *Factory Act*; but it was carried out very imperfectly, the men being often compelled to support a fund out of which the employers' fines were paid. Tom Sadler's *Ten Hours Bill* of 1832 was lost through the opposition of the manufacturers; and Lord Ashley's Bill, which restricted the working hours of adults, was met by the appointment, under Whig auspices, of a Royal Commission. The report of this Commission (1833-34) took the view of the capitalists, that such a restriction would so diminish production as to put them at the mercy of foreign competition. On its recommendations was based Lord Althorp's *Act* of 1834, which first made the distinction between children and young persons, and began the system of working children in relays, so as to permit of daily education. The alternate day system (with an extension of the hours for schooling) was further developed in the important *Factory Act* of 1844. A uniform working day from 6 A.M. to 6 P.M., with a fixed  $1\frac{1}{2}$  hour for meals, was at last established for all protected persons by the *Act* of 1850. Manual work had been diminishing in many trades; and in 1861 several restrictions were placed on lace-factories and on bakehouses. The Report of Lord Shaftesbury's Commission of Inquiry was in 1861 well received by the employers, who were now more alive to the advantages connected with sound sanitary conditions for labour. The pottery trade was first dealt with in 1864. The Commission also made thorough inquiry into the question of small shops and workrooms used in connection with larger establishments. The legislation which

resulted from the Commission's labours took the double form of a *Factory Act Extension Act*, 1867, and a *Workshops Regulation Act*, 1867, which for the first time declared that all work done for wages by young persons and women should be placed under supervision and be subject to distinct regulations. Further provisions were made in 1870 and 1874, but the local authorities did not properly enforce the law.

Hence the necessity arose in 1876 for the Royal Commission on *Factory and Workshop Acts*, which reported that previous legislation had been to a large extent successful, and that, while some occupations were still undoubtedly unhealthy in spite of the sanitary regulations of these acts, the cases in which young children were employed in labour unfitted for their years, or in which young persons and women suffered physically from overwork, had become uncommon. The Commissioners, however, proposed large changes in the law, and in particular they proposed the consolidation of the law, which was accomplished by the *Factory and Workshop Act*, 1878. This great statute deals with five classes of works: (1) Textile factories, such as cotton-mills; (2) non-textile factories, including an immense variety of trades, of which iron-works, paper-mills, and print-works are examples; (3) workshops generally, in which mechanical power is not used, and where the employer has the right of access and control; (4) workshops in which none but women above the age of eighteen are employed; (5) domestic workshops, in which the work is carried on in a private house, room, or place in which the only persons employed are members of the same family dwelling there. In some cases—e.g. bakehouses, shipyards, hat-works, &c., the place is regarded as a factory or a workshop according to the use, or not, of mechanical power. In class 1, where power is used, and the large majority of workers are women and children, the highest degree of regulation is reached. In class 2, where the labour is not so hard, or the strain of attendance on the moving power not so heavy, the statutory hours of work are somewhat relaxed, but education and sanitary provisions are still compulsory. In class 3 registers of children and young persons, and certificates of age and fitness, are, except in special circumstances, dispensed with. In class 4 the hours for work and meals may be changed, and the sanitary authority is responsible for the sanitary state of the shop. In class 5 there is still greater elasticity as regards hours for work and meals; the Medical Officer of Health inspects the sanitary condition, but the employment of women is entirely unrestricted. Straw-plaiting, pillow lace-making, glove-making, and some other handicrafts of a light character may be carried on by a family in a private house or room, without fixing on the premises the legal liability of a workshop. Again, if the manual labour is exercised only at irregular intervals, and does not furnish the principal means of living to the family, the house will not become a workshop.

Under the *Act* of 1878 a 'factory' means a place in which machinery is moved by the aid of steam, water, or other mechanical power; a 'child' means a person under the age of fourteen years; a 'young person' means a person between fourteen and eighteen years of age; a 'woman' means a woman of eighteen years and upwards; 'parent' includes the person having the custody or control of any child; 'night' means the period between 9 P.M. and 6 A.M. The general *sanitary provision* applicable to all factories and workshops is that they shall be clean, free from offluvia, not overcrowded, and ventilated so as to render harmless, so far as practicable, the gases, vapours, dust, &c. which

are generated in the process and are injurious to health. Where anything is wrong, the factory inspector gives notice to the sanitary (local) authority. Every factory is to be lime-washed once in 14 months, unless painted in oil once in 7 years, when it must be washed once in 14 months. The inspector may order fans to be used where dust is generated by grinding, glazing, or polishing on a wheel. The machinery in a factory, and certain other sources of danger, must be fenced. Children must not be set to clean any part of the machinery while in motion. No work is to be done between the fixed and traversing parts of a self-acting machine while moved by mechanical power. The general hours for the employment of young persons and women in textile factories are 6 A.M. to 6 P.M., or 7 A.M. to 7 P.M., except on Saturdays, and on Saturdays 6 A.M. to 12.30 or 1 P.M. (according to the time allowed for meals), or 7 A.M. to 1.30 P.M. Two hours (one of them before 3 P.M.) must be allowed for meals on every day except Saturday, on which half an hour is sufficient. The employment is not to be continuous for more than  $4\frac{1}{2}$  hours without an interval of half an hour for meals. The variations on these rules for young persons and women in a non-textile factory, and for young persons in a workshop, are that the minimum time for meals is reduced to  $1\frac{1}{2}$  hour, and the period of continuous employment is extended to 5 hours. As regards children in textile factories, they must be employed on the system of morning and afternoon sets, or on that of alternate days. Their morning set ends at 1 P.M., or at dinner-time, if that is earlier; the afternoon set begins at 1 P.M., or after dinner, if that is later. The Saturday hours for children are the same as for others. Neither set is to be continued more than seven days, and no child may be employed on two successive Saturdays. Under the alternate day system, the hours for employment and meals are the same as for young persons.

In workshops in which neither children nor young persons are employed the hours for women are 6 A.M. to 9 P.M., with  $4\frac{1}{2}$  hours for meals and absence; and on Saturdays 6 A.M. to 4 P.M., with  $2\frac{1}{2}$  hours for these purposes. As regards domestic workshops, the actual times for work and meals are not fixed, but overtime is prohibited, and the shops remain under the sanitary supervision of the local authority. The two points fixed by statute with reference to meals in factories and workshops generally are: That the three classes of children, young persons, and women must have their meals at the same hour; that during that hour none of them is allowed to remain in a room where the manufacturing process is being carried on. In every factory and workshop the period of employment, prohibitions, meal hours, and system of children's labour must all be published in a notice put up within the premises. Employment of children under ten, and of any of the protected classes on Sunday, is prohibited. The occupier is also bound to give eight half-holidays in every year besides (in Scotland) the sacramental fasts or substituted holidays. In trades connected with the retail business the Home Secretary may authorise the giving of separate holidays to different classes of workers; and in other cases (e.g. in provincial towns where Saturday is the market-day) he may substitute another week-day for the Saturday half-holiday. A child employed on the morning and afternoon set must give one school attendance on each work day, and, if employed on the alternate day system, two attendances on each non-working day. The penalty is that the child cannot be employed in the following week before the deficiency in attendances has been made up. It is the duty of the

employer to get every week from the teacher a certificate of attendance. He may also be obliged to pay to the school-manager a sum not exceeding 3d. a week, or one-twelfth part of the child's weekly wages. A child of thirteen, however, on obtaining a certificate of proficiency, will be treated as a young person. No child or young person under the age of sixteen is to be employed in a factory for more than seven days without a certificate of age and physical fitness granted after personal examination by the medical officer or certifying surgeon of the district. When an accident occurs in a factory or workshop which causes loss of life, or prevents the person injured resuming work within 48 hours, notice must be given to the inspector and the medical officer or certifying surgeon, the latter of whom must go at once to the premises and report to the inspector on the nature and cause of the death or injury.

It is impossible to mention all the special restrictions which the act imposes. For instance, no children or young persons are allowed to work at silvering mirrors by the mercurial process, making white lead, melting or annealing glass. Children must not be employed in dipping lucifer matches, or dry-grinding in the metal trade. Girls must not be employed in making or finishing bricks or salt. In glass and earthenware works and others, certain parts of the works must not be used for taking meals. The Home Secretary has power to extend such restrictions to other unwholesome occupations. Again, where the customs and exigencies of a trade require it, the Home Secretary may alter the hours of labour to 8 A.M. and 8 P.M., or even 9 A.M. and 9 P.M. Of the first class, lithographic printing, envelope-making, biscuit-making, and bookbinding are examples; of the second, the straw-hat making at Luton, and warehouses in London and elsewhere. The existing state of factory regulation therefore depends largely on a series of orders in council outwith the statute.

The administration of the act is carried on by inspectors appointed and paid by government. They have large powers of entering factories, workshops, and schools, of asking for documents, of examining persons on oath. A special warrant is required to enter a dwelling-house. The certifying surgeons appointed by the inspectors are entitled to charge for their statutory duties certain fees, which are paid by the employer, but which he may deduct from wages.

It must be borne in mind that the success of the statutory supervision of labour depends greatly on the energy and wisdom of the inspectors, and that much of the good done in Great Britain is due to such men as Messrs Redgrave and Baker. The appointment of inspectors of artisan training, and in certain cases of women, is regarded as important.

Legislation of this kind has been much more fully developed in Great Britain than in the United States or on the Continent. In the United States there is no corresponding system of national legislation as to the conditions of factory labour, though a certain number of the states have passed laws fixing the hours of labour, &c. in certain industries. An International Labour Conference of delegates appointed by various governments was held at Berlin in 1890.

See the Parliamentary Reports of 1841-42, 1862-66, 1875, and, for the factory regulations in the United States, Austria, Belgium, &c., those of 1882. Authorities are Taylor, *Introduction to a History of the Factory System* (1886), and *The Modern Factory System* (1891); Jeans, *Factory Act Legislation* (1891); Von Plenier, *Die Englische Fabrikgesetzgebung* (Eng. trans. 1873); Engels, *Lage der arbeitenden Klassen in England*; Marx, *Das Kapital*; Faucher, *Études sur l'Angleterre*;

Alfred's *History of the Factory Movement*; Fielden's *Curse of the Factory System*; Sadler's *Factory System*. Reference may also be made to the report of a Select Committee on the Shop Hours Regulation Act of 1886 (with which the name of Lubbock is associated), and to the valuable reports from the United States and Europe as to hours and regulations of labour, obtained by the Foreign Office in 1882. The chief inspector makes an annual report (embodying special reports) to the Home Office. In the Local Government Acts of 1888 and 1889 power is taken to transfer the responsibility in these matters from the Home Office to the new County Councils.

**Faculæ** (Lat. *facula*, 'a torch'), in Astronomy, arc spots, brighter than the rest of the surface, which are sometimes seen on the sun's disc. See SUN.

**Faculty**, a name formerly applied by philosophers (Reid, Hamilton, &c.) to each of the primary or fundamental powers or functions of the mind. But the view on which this nomenclature was based is rapidly becoming obsolete. According to modern psychology, the mind is a unity, and the so-called faculties are the different specific directions or modes in which its energy works. See PSYCHOLOGY. For the faculty of a university, see UNIVERSITY.

A *Grant of Faculty by the Ordinary* is an order by the bishop of a diocese to award some privilege not permitted by common law. A faculty is necessary in order to effect any important alteration in a church, such as the erection of a gallery or of an organ. Without a faculty, a person is not entitled to erect a monument within the walls of a church. —The *Court of Faculties* is a court established by Henry VIII., whereby authority is given to the Archbishop of Canterbury and his successors to grant dispensations and faculties, an authority formerly pertaining to the pope. The sittings of the court have always been held at Doctors' Commons (q.v.). Of late years the court has been chiefly occupied with granting licenses to marry without publication of banns. See ECCLESIASTICAL COURTS, LICENSE, MARRIAGE, DISPENSATION.

**Fæces**, the solid excrements, the matters which an animal ejects from the lower end of the intestinal canal, and in greater part consisting of those portions of food which, on passing through the alimentary canal, have been rejected as comparatively worthless in the office of nutrition. In the higher animals the fæces generally contain about three-fourths of their weight of water, the remaining one-fourth consisting in greater part of organic remains; in the case of the ox, sheep, and other herbivorous animals, of undigested woody fibre. See DIGESTION, MANURE.

**Fæd**, JOHN, a Scottish painter, was born in 1820 at Burley Mill, near Gatehouse-of-Fleet, Kirkcudbrightshire, where his father was an engineer and millwright. His love of art was manifested at an early period, and when hardly entered on his teens he was in the habit of making tours through the villages of Galloway, painting miniatures. In 1841 he went to Edinburgh, where his talents ultimately won recognition; and he was elected an A.R.S.A. in 1847, an R.S.A. in 1851. His first picture that obtained popularity was 'The Cruel Sisters' (1851). Since then he has executed, among other works, 'Shakespeare and his Contemporaries,' 'The Cotter's Saturday Night,' and, after settling in London in 1864, 'The Wappenschaw,' 'Tam o' Shanter,' 'Haddon Hall of Old,' 'The Stirrup Cup,' 'John Anderson my Jo,' and 'The Hiring Fair.' In 1880 he returned to Gatehouse-of-Fleet, and his most recent pictures have been chiefly landscapes.

**Fæd**, THOMAS, R.A., brother of the preceding, was born at Burley Mill, 8th June 1826, and in 1842 began his regular art studies in Edinburgh. At the Trustees' Academy he took several prizes;

the first picture he exhibited was a water-colour of an incident from the *Old English Baron*. Shortly after, he discovered his true strength in 'Reading the Bible,' a simple subject from Scottish peasant life, and he was made an Associate of the Royal Scottish Academy in 1849, in which year he produced an interesting work entitled 'Scott and his Friends at Abbotsford,' which was engraved by his brother James Fæd. In 1852 he removed to London, where his 'Mithenless Bairn,' exhibited in 1855, a popular and taking composition, was declared by some critics to be 'the picture of the season.' Of his subsequent works we need mention only 'Home

the Clan.' Fæd was made A.R.A. in 1861, R.A. in 1864, and elected an honorary member of the Vienna Royal Academy in 1875.

**Faenza**, a town of Italy, 31 miles SE. of Bologna by rail, has an imposing cathedral, a fine market-place surrounded with arcades and adorned with a fountain, and numerous palaces and ecclesiastical edifices. Its manufacture of glazed and coloured earthenware vessels, in Italy called 'majolica,' and in France 'faience,' has declined in importance, and its chief industries now are the making of silk, linen, and paper. Pop. 13,998. Faenza, the ancient *Faventia*, at one period a town of the Boii, and afterwards a *municipium* under the Romans, fell under the power of the Manfredi family; in 1509 it was captured by Pope Julius II.; and in 1860 it passed, along with the Emilian provinces, to the kingdom of Italy.

**Fagging**, a usage in the great public schools of England, in virtue of which the senior boys are authorised to exact a variety of services from the junior boys. A lower form boy has certain duties to perform to all the upper form boys, as in stopping the balls for them when practising cricket—and others which he owes to a special master, such as stoking his fire and carrying his messages, of a more or less private kind. The risk of capricious exercise of the senior boys' privileges in harassing or humiliating the juniors is sufficiently obvious; but, on the other hand, the system is said by its defenders to make boys handy, helpful, and docile, while taking the nonsense out of bumptious lads. And the argument chiefly relied on in its favour is that the relation thus established between seniors and juniors prevents bullying. The origin of the usage, which is prominent in tales of school-life, such as *Tom Brown's School-days*, is sought for in the necessity felt in great boarding-schools for a scheme of definite relations amongst the boys, so as to secure definite rights and immunities during the time when they are not in the teacher's presence. A similar usage, called *Pennalism*, sprang up in the German universities in the 17th century; and the freedoms taken, under the name of *hazing*, by sophomore and senior students with freshmen in the American colleges is somewhat analogous. See PUBLIC SCHOOLS.

**Faggot-votes**, votes manufactured, chiefly for county elections, by the nominal sale of property, under mortgage or otherwise, so as to qualify the holder to vote. The extension of the county franchise has left faggot-votes practically no longer worth the trouble of procuring. The term *faggot* described formerly a person who was hired to fill up another's place at the muster of a regiment, or to conceal a deficiency in its strength.

**Fagotto**. See BASSOON.

**Fahln**. See FALUN.

**Fahrenheit**, GABRIEL DANIEL, the improver of the thermometer and barometer, was born at

Danzig, 14th May 1686. He was originally destined for a commercial career, but he early abandoned trade for natural philosophy, and, after travelling through Germany and England, settled in Holland. About 1714 he conceived the idea of using quicksilver instead of spirits of wine in the construction of thermometers, by means of which the accuracy of the instrument was very much improved (see THERMOMETER). He fixed his freezing-point at 32° to avoid negative measurements. In 1724 Fahrenheit was elected a Fellow of the Royal Society of London; and the *Philosophical Transactions* of that year contain several papers by him on points in natural philosophy. He died 16th September 1736.

**Faidherbe**, LOUIS LÉON CÉSAR, French general, was born at Lille on 3d June 1818. His apprenticeship as a soldier was passed in Algiers and Guadalupe. His activity as a seasoned soldier connects him with the history of the French colony of Senegal, and with the Franco-German war of 1870-71. Proceeding to Senegal in 1852, he became two years later governor of the colony, and in that capacity not only reduced to complete submission several more or less tributary tribes, but also extended the frontiers of the colony by the subjugation of the Moorish Tarza in 1858, and of the country of Cayor in 1861. Under the dictatorship of Gambetta, Faidherbe was summoned to France in December 1870, and given command of the army of the North. After successfully withstanding Manteuffel's attack near the river Hallue, 23d December, he was severely beaten near St Quentin on 19th January 1871. After the conclusion of peace, he was despatched by the French government to Upper Egypt to study the monuments. He died at Paris, 28th September 1889. Faidherbe published useful books on the language, geography, and archaeology of northern Africa, chief amongst which are two collections of *Numidian Inscriptions* (1870-72), *Anthropology of Algiers* (1874), *Épigraphie Phénicienne* (1873), *Le Soudan Français* (1884), a work on *Senegal* (1889), and treatises on the *Poul Language* (1875) and the *Berber Language* (1877). His *Campagne de l'Armée du Nord* appeared at Paris in 1871.

**Faience**, or FAYENCE, a general term for glazed earthenware and porcelain, derived from the town of Faenza (q.v.).

**Fainéants Rois** (the 'Do-nothing Kings'), the sarcastic designation of the later Merovingian sovereigns of France, under whom the famous Mayors of the Palace really governed the country. The first of the series was Thierry III., nominally monarch of Burgundy, Neustria, and Austria (i.e. Austrasia); the others were Clovis III., Childbert III., Dagobert III., Chilperic II., Thierry IV., and Childeric III. The last of these was dethroned in 730 by Pepin le Bref, Mayor of the Palace, who caused himself to be formally proclaimed king. Louis V., the last of the Carolingians, and a descendant of Pepin le Bref, also received the epithet of *Fainéant*.

**Fainting**, or SYNCOPÉ (Gr.), is a condition in which, owing to a sudden mental or bodily impression, the circulation of blood is temporarily arrested or very much diminished in force and volume, the respiration and the functions of the nervous system being likewise suspended. The indications of fainting to a bystander are chiefly a sudden pallor, accompanied by loss of power over the limbs, with disappearance of the pulse and movements of respiration; the eyes are commonly half-open or closed, the countenance bloodless, but quite at rest, and not indicative of suffering or disturbance: the flaccid, motionless condition of all the limbs also tends to distinguish simple fainting from

epilepsy and the other diseases attended with spasm; whilst the vanishing of the colour and the suppression of the pulse make a marked distinction between fainting and Catalepsy (q.v.) and other forms of Hysteria (q.v.); with which disorders, however, fainting may in some cases be associated. Minor degrees of fainting, where there is no more than a feeling of faintness and a little pallor, are also common. The mode and origin of fainting and the study of its phenomena alike lead to the conclusion that it is primarily an impression upon the nervous system, very much of the same nature as the Collapse, or shock of a severe bodily injury; this reacts, in the first instance, on the heart, and through the circulation on all the other functions of the body. Fainting may end in death, if too prolonged, or if associated with disease of the internal organs, and especially of the heart. See HEART (DISEASES OF THE). Ordinarily, a person who faints from mental emotion, a hot and close atmosphere, or other transient cause, is readily restored by being laid on the back with the head low, and allowed plenty of cool, fresh air. If the patient is or can easily be placed in a sitting posture, he is often still more quickly brought round by making him bend forward with the head between the knees. The worst possible treatment is to raise him or hold him up, the course nevertheless instinctively adopted by almost every one. Any tight articles of dress should be loosened, and a stream of cold air, or a little cold water, should be directed to the face and neck, so as to arouse the respiratory movements. It is desirable, also, to apply ammonia or aromatic vinegar to the nostrils; but a more effective way of exciting the respiration is to compress the ribs and allow them to expand again, so as to imitate the natural movement. A little alcohol or sal volatile should be administered if the patient can swallow. Care should be taken to ascertain that there is no obstruction in the throat or air-passages, as suffocation from mechanical causes has been mistaken for fainting, and the real origin of the mischief overlooked, with fatal consequences. Should all other means fail, electricity (see ELECTRICITY, MEDICAL) will sometimes succeed in restoring the respiration and heart's action.

**Faloum**. See FAYUM.

**Fair**. See FAIRS.

**Fairbairn**, ANDREW M., a learned theologian, was born in Edinburgh in 1839, studied at the university there, and after the requisite theological training became pastor of an Evangelical Union church at Bathgate, from which he obtained leave of absence to pursue his studies in Germany. After his return he preached in Aberdeen until his able theological writings earned him in 1878 the principalship of the Congregational College at Airedale near Bradford. In the same year he was made D.D. by his own university, and in 1881-83 he was Muir lecturer there on comparative religions. His brilliant and learned essays in the *Contemporary Review* early attracted attention, and his *Studies in the Philosophy of Religion and History* (1876), *Studies in the Life of Christ* (1880), *Christianity in the First and Nineteenth Centuries* (1883), *The City of God* (1883), and *Religion in History and in the Life of To-day* (1884) established his reputation as one of the profoundest religious thinkers of his day. In 1888 he was appointed principal of Mansfield College, a Congregationalist college at Oxford.

**Fairbairn**, SIR WILLIAM, was born at Kelso, in Roxburghshire, 19th February 1789. Having got some plain schooling, he was apprenticed (1804) to an engine-wright at Percy Main Colliery, North

Shields. Here he was assiduous in self-improvement, gained a knowledge of mathematics, read extensively, and made the acquaintance of George Stephenson, which was continued through life. His apprenticeship over, he moved about a good deal, till in 1817 he started business on his own account in a humble way in Manchester. It was a struggle in which, without money or connections, only great abilities and perseverance could succeed. The first great improvement introduced by Fairbairn was the substitution of iron for wood in the shafting of cotton-mills, and the substitution of light for heavy shafting where metal was already in use. This extended his reputation, and orders flowed in faster than they could be executed. Fairbairn was amongst the earliest of the iron ship-builders, his plan of using iron boats on the Forth and Clyde Canal being the first suggestion in this direction; and in their construction he originated various improvements. His works (1835) at Millwall, London, turned out several hundred vessels, but, as they did not prove a financial success, he parted with them, after fourteen years' experience, at a loss. In 1834-35 Fairbairn and Mr E. Hodgkinson were invited by the British Association to seek out the cause of certain supposed defects in the iron produced by hot-blast furnaces. About the same time Fairbairn tested the strength of the various kinds of iron of Great Britain.

The first idea of a tubular bridge across the Menai Strait is due to Robert Stephenson, but its realization was largely the work of Fairbairn. Stephenson's idea was a circular tube, supported by chains; but the Britannia and Conway bridges are rectangular structures, without chains, invented and designed by Fairbairn (see *BRIDGE*, Vol. II. p. 440). He patented his design, and erected more than a thousand bridges upon this principle. He devised improvements in connection with steam-boilers and other steam machinery, and was the inventor of a tubular crane. He aided Joule and Sir W. Thomson in 1851 in their investigations of the earth's surface, and guided the experiments of the government committee (1861-65) in the application of iron for defensive purposes. Fairbairn was a chevalier of the Legion of Honour, and was created a baronet in 1869. He published a good many works and papers on iron, bridges, boilers, mills, &c. He died at Moor Park, Surrey, 18th August 1874. See his Life by W. Pole (1877), and Smiles's *Lives of the Engineers* (1892).

**Fairfax**, EDWARD, the translator of Tasso's *Jerusalem Delivered*, was a son (perhaps a natural son) of Sir Thomas Fairfax of Denton, in Yorkshire. The year of his birth is not known, but is believed to have been about 1580. His life was spent quietly, in literary pursuits, at Fewston, near Otley, where he died in January 1635. His translation of Tasso's *Gerusalemme Liberata* (1600) was dedicated to Queen Elizabeth. For poetical beauty and freedom it has been the theme of universal praise. Dryden ranked Fairfax with Spenser as a master of English, and Waller said that he derived from him the harmony of his numbers. Hallam, much less enthusiastic, says that it lacks the grace of the original, though not wanting in spirit and vigour. Fairfax also wrote a *Discourse of Witchcraft* (1621), describing how two of his own daughters were bewitched. It was published by Monckton Milnes in the *Miscellanies* of the Philobiblon Society (1858-59).

**Fairfax**, THOMAS, LORD, generally known as Sir Thomas Fairfax, parliamentary general, was the son of Ferdinando, Lord Fairfax, and was born January 17, 1612, at Denton, Yorkshire. He studied at St John's College, Cambridge, and from 1629 served as a volunteer in Holland,

under Lord Vere, whose fourth daughter, Anne, he married (1637) shortly after his return to England. On the outbreak of the Civil War in 1642 Fairfax espoused the cause of the Parliament, and was appointed general of horse under his father, who commanded the parliamentary forces in the north. He distinguished himself so much by his valour, prudence, and energy, especially at Marston Moor (1644), where he was wounded, that in 1645, when the Earl of Essex resigned the office of general of the parliamentary forces, Fairfax was appointed to the supreme command; but the real ruling genius of the army was Cromwell, who had risen to be lieutenant-general. In June 1650, on Fairfax's refusal to march against the Scots, who had proclaimed Charles II. king, Cromwell was appointed commander-in-chief in his stead. Fairfax now withdrew into private life. After the death of Cromwell he laboured for the restoration of the king, and gathered troops to assist General Monk against Lambert. He was appointed head of the commission despatched to the Hague in 1660 to arrange for the return of Charles II. He died at Nunappleton, Yorkshire, 12th November 1671. Fairfax wrote several works, prose and poetic, including two memoirs on the Civil War. See his *Correspondence* (4 vols. 1848-49), and a *Life* by C. R. Markham (1870).

**Fairford**, a village of Gloucestershire, 9 miles E. of Cirencester, and 26 WSW. of Oxford. Its fine Perpendicular church, built by John Tamo in the 15th century, is famous for its splendid series of twenty-eight stained-glass windows, often erroneously attributed to Albert Dürer, but really of Flemish workmanship. Keble was a native. Pop. of parish, 1525. See the Rev. J. G. Joyce, *The Fairford Windows* (fol. 1872).

**Fair Head**, or BENMORE, a precipitous promontory of the north coast of Antrim, Ireland, opposite Rathlin Isle, which is 4 miles to the NW. It rises 636 feet above the sea, and consists of carboniferous strata, overlaid by greenstone columns, 20 to 30 feet thick, and 280 to 300 feet high.

**Fairies**, **Elves**, supernatural beings, generally of human form but diminutive size, a belief in whom has been among the superstitions of the greater portion of the European nations. The word *elf* is from the Anglo-Saxon *elf*, which corresponds to the Danish *alf*, the Icelandic *álfr*, and the German *alp*; but the Germans adopted in the 17th century *elf* and *elke*, from the English for the same idea. Fairy is properly enchantment, or the realm of fairy spirits, *fay* being originally the name of the sprites themselves. Fay (Low Lat. *fata*, 'fairy'; Fr. *fee*) is from Lat. *fatum*, 'fate,' and once meant the goddess of destiny. From the Old French *fue* (= *fee*) comes *fuerie*, 'enchantment;' whence fairy. The Celtic fées or fairies are undoubtedly relics of those *matres* and *matronæ* which appear on Gallo-Roman inscriptions as objects of popular belief. After the transference of the Teutonic and southern nations to northern elves (which were originally of two kinds—the light elves, or elves proper, and the dark elves, or dwarfs) became mixed up with their Celtic kindred, the fairies, in inextricable confusion.

Tracing back the antecedent history of this widespread belief, various fanciful theories have been suggested to explain its origin and growth; most of which cannot be accepted as satisfactory. But, like many other survivals of superstition, it is probably to be connected with the mythological conceptions of the Greeks and Romans; some folklorists referring the fairy to the Paræ or Fates of primitive times, who were supposed to rule the destiny of man. The long occupation of Gaul by the Romans familiarised its natives with their

mythological conceptions of nymphs and fauns; and indeed these closely resemble in many particulars the famous fays of the medieval romances. Again, the native Gauls themselves had a large pantheon of topical divinities, and doubtless these became fused with the other traditional figures, whether due to creative imagination or to more or less direct transmission, and thus helped to create the composite product forming the fairydom of our folklore, which through such literary mediums as the work of Straparola and the *Pentamerone* of Basil has exercised a profound influence upon western Europe. Fairies in literature have received the most different treatment: thus, Boiardo's, Ariosto's, and Spenser's fairies are mere diminutive men, with all the ordinary human emotions, while in the Oberon and Titania of Shakespeare's *Midsummer Night's Dream*, and in the fairies that touched the imaginations of Ben Jonson, Herrick, Drayton, and even the youthful Milton, we find that the aerial and supernatural quality is the predominant feature in the characterisation. Altogether they are more romantic and interesting figures, and at the same time in their other-worldly conception are more real to the human imagination.

Comparatively modern fairy legends tell us how these little beings preside at the birth of man; and we know how at the birth of Ogier le Danois six fairies attend, five of whom give good gifts. In those parts of the world where there are mountains, mists, dangerous morasses, cataracts, and stormy oceans, all superstitions, being a belief in supernatural agencies, are naturally exaggerated, and, from the dangers to which the people are liable from the agencies they deem supernatural, the belief takes deep root in their minds. Accordingly, in flat and well-cultivated countries like England, the fairy superstition is simple and homely, connecting itself with matters of domestic routine, such as the sweeping of the dwelling-house, the skimming of the milk, the preservation of the butter, and the like, numerous allusions to which are found in Shakespeare. In Scandinavia and the Highlands the fairy people are connected with storms and convulsions, betray people to their death, fly away with them into the infinite cloud-land, or lead them through endless caverns within the earth. It has been observed as a further distinction that the fairies of the German or Teutonic tribes are more harsh, fierce, uncanny, or deformed than those of the Celtic nations, which have a tendency rather to the aerial and the graceful. Still the amount of common characteristics in the superstition throughout Europe is enormous. Its peculiarities have been found so much more emphatically displayed in Scandinavia than elsewhere as to have suggested the earlier and less philosophical view that modern fairydom is merely a remnant of the old mythology of the northern nations, communicated by them to a greater or less extent in all the countries over which their vikings carried their ravages.

There is a further distinction between the fairies of poetic and heroic literature and those of popular belief—the former being princes and princesses of chivalry, only distinguished from human beings by their superhuman superiority in all the qualities which elicited respect in the age of chivalry; while those of popular belief are small in stature, sometimes decrepit, and endowed with dispositions generally more allied to malignity than magnanimity. In Ireland and the Highlands they have been spoken of as a wandering remnant of the fallen angels, and in the west of England the pixies are the souls of infants who died before they were baptised. Sometimes they

are supposed to be human beings, metamorphosed or disembodied, and this form of the superstition has made fairyland a place of purgation for those whose sins have condemned them to it. The analogy is carried out in the belief that the services of the living can extricate the souls so situated; but it is rather through dexterity and courage than pure piety that the feat is achieved, and the rescues from fairyland form some of the most wild and exciting of the elfin narratives—as, for instance, the exquisite ballad of *Tamlane*. The only dark cloud that obscures the brightness of fairydom is the periodical necessity of paying a teind to hell—a necessity which casts unexpected light upon the radical affinities of the fairies, in spite of all the seeming gaiety and happiness of their world. Hence their desire for kidnapping human children, in order to pay with them the inevitable tribute. Again, they do not possess spiritual souls like men and women, and consequently have no immortality of existence—this notion forms the heart of the most exquisite of artistic fairy-tales, the *Undine* of Fouqué.

There is still another broad distinction into fairies that dwell in the upper air and fairies that dwell within the bowels of the earth, while a third class frequent the waters. The Scandinavians called the fairy inhabitants of the air white elves, those of the earth black. Whatever was genial, light, playful, and benevolent in the superstition clustered round the former; the latter did all the work that was dark, cruel, and rapacious. Naturally enough, the black or subterranean kind frequented mining districts, where they might be seen extracting the ore for themselves, and thus unwittingly leading the miner to rich veins of metal. They might be seen in an occasional peep through an aperture of a hill in their underground retreats, in chambers supported on jasper columns, where they were stowing away their ample stores of gold and silver. Some of the most exciting tales about the German *gnome*, and the Irish *leprechaun*, who was a creature of the same kind, are founded on the efforts of adventurous mortals to get possession of their riches. There exists a legend, occurring in nearly identical terms in several countries, which connects some piece of valuable plate belonging to a church with the underground fairies. The story of the horn of Oldenburg is a type of these narratives. Pictures represent it as a beautiful drinking-vessel, in the shape of a horn, exquisitely decorated with the finest fanciful silver-work, in the style contemporary with the richest Gothic architecture. The legend is that one day Otho of Oldenburg, being exhausted with hunting, and very thirsty, exclaimed, 'O God, would that I had a cool drink!' Thereupon there appeared before him, as if coming out of the rock, a lovely maiden, who offered him a drink in the fairy-horn. He made off with it, and saved himself from evil consequences by bestowing it on the church. Hence these relics are generally in churches; but one of them is still in the possession of an English family, and, as their prosperity was traditionally believed to depend on retaining it, it was called the 'Luck of Eden Hall.'

*Puck and the pixies belong to the same class of beings.* Of the elf-folks of Scandinavia, the male is old and ill-favoured, but the evil element in the elf-woman or elf-maid consists in her beauty, which renders her perilous to romantic and lovelorn youths, whom she beguiles either with her own charms or by assuming the aspect of their mistress. To our own literature belongs one beautiful story of this character—the ancient tale of the love between 'True Thomas' and the Queen of Fairyland, which the genius of some nameless maker has woven into imperishable verse. A common feature, both here

and elsewhere, in the stories of fairy-women who assume human form and give their love to men, is a restriction of some nature which must not be broken. All mermaids, lamias, and the like are subject to some such conditions. Thus, Melusine is once a week again a serpent from the waist downwards, and when her husband breaks her one condition and surprises her at her bath, she becomes a water-sprite again.

In Ireland, and also in the Border country of Scotland, the fairy superstition has been incorporated into innumerable poetic legends and mystic traditions. T. Crofton Croker, in his *Fairy Legends and Traditions of the South of Ireland* (3 vols. 1828), presents a full and amusing account of the Irish fairies or elves, which he describes as 'a few inches high, airy, and almost transparent in body; so delicate in their form that a dew-drop, when they chance to dance on it, trembles indeed, but never breaks. Both sexes are of extraordinary beauty; and mortal beings cannot be compared with them.' They do not live alone, or in pairs, but always in large societies, and are governed by a queen. The same author adds: 'They are invisible to man, particularly in the daytime, and, as they can be present and hear what is said, the peasantry never speak of them but with caution and respect, terming them the good people, or friends. They have their dwellings in clefts of rocks, caves, and ancient tumuli. Every part within is decorated in the most splendid and magnificent manner; and the pleasing music which sometimes issues from thence in the night has delighted those who have been so fortunate as to hear it.' There are Irish fairies, however, of more special character. Among these are the *banshee*, or female spirit who watches a particular family; the *leprechaun* or *cluricaun*, an elf of evil disposition, who usually appears as a wrinkled old man, and has a knowledge of hidden treasure; and the *pooka*, a spirit of diabolical disposition, who sometimes appearing as an eagle or a black horse hurries the person he gets possession of to destruction. Of similar varieties are the Scottish elves: the *browmie*, or domestic spirit nearly corresponding to the Banshee; and the *kelpie*, a kind of water-horse, not unlike the Pooka, and in form somewhat analogous to the being sung by Leyden in his charming ballad, 'The Cont of Keeldar' (*Minstrelsy of the Scottish Border*):

'Brown dwarf, that o'er the muirland strays,  
'Thy name to Keeldar tell!'  
'The Brown Man of the muirs, who stays  
Beneath the heather-bell.'

Fairies cannot be seen by mortal eyes with impunity—it is the main part of Falstaff's terror when he sees his assailants: 'They are fairies; he that speaks to them shall die' (*Merry Wives*, V. v.). But the greatest risk that mortals run from the denizens of fairyland is that already alluded to, of having their children stolen from the cradle, and a changeling substituted who bears a resemblance to the stolen infant, but is an ugly little creature and never thrives. On this theft of a maid, who is carried to fairyland, but in the course of time returns to her parents, James Hogg founded his fine ballad of 'Kilmeny' (*Queen's Wake*).

Besides being embalmed in imaginative literature, the fairy has a perpetual memorial in the small, exquisitely shaped arrow-heads found so abundantly in northern countries, where they were long known as elf-arrows, or bolts with which the more malignant fairies sometimes slew or injured cattle and human beings; thus, when a poor man's cow or heifer was suddenly affected with some deadly and incomprehensible illness, it was said to be 'elf-shot.' See ELF-BOLTS.

See especially Keightley's *Fairy Mythology* (1850), and the articles DEMONOLOGY, and FOLKLORE; also Ritson's

*Fairy Tales* (1831); Halliwell's *Illustrations of the Fairy Mythology of a Midsummer Night's Dream* (1845); Schreiber, *Die Feen in Europa* (Freiburg, 1842); Maury, *Les Fées du Moyen Âge* (Paris, 1843); Grimm's *Deutsche Mythologie* (1835; 4th ed. 1875-78; Eng. trans. 4 vols. 1879-88); and Wirt Sikes, *British Goblins* (1879); also the collections of fairy tales of Grimm, Crofton Croker, Von Hahn, J. F. Campbell, Dasent, Ralston, &c.

**Fair Isle**, a solitary Shetland island, 24 miles SSW. of Sunburgh Head. It is 3 miles long by 2 broad, and 3 sq. m. in area, with high rocky cliffs and promontories, rising in the Sheep Craig to a height of 480 feet. Pop. (1861) 380; (1881) 214, chiefly engaged in fishing, or knitting woollen articles. There are a public school and a Church of Scotland mission here. At Stromecleir Creek was wrecked, in 1588, the Duke of Medina Sidonia, admiral of the Spanish Armada. He escaped with a few of his crew; and from these shipwrecked Spaniards the natives of Fair Isle are said to have acquired their knowledge of the art of knitting parti-coloured woollen articles.

**Fairs** (Fr. *foire*, from Lat. *feriæ*, 'holidays'), great periodical markets, some of which are chiefly devoted to one kind of merchandise, while others, of a wider scope, afford opportunity for most of the sales and purchases of a district. Fairs have long been regularly held in most parts of Europe and in many parts of Asia; but, as they belong rather to a state of things which is passing away than to modern civilisation, they have not been established or have not acquired the same importance in America. In Italy, towards the close of the 5th century, we first find authentic accounts of fairs specially designed as marts for commerce, and in Greece it has been suggested that at the celebrated Greek games trade was no entirely subordinate object. Thus, Cicero tells us that as early as the age of Pythagoras large numbers of people attended the religious games for the purpose of trading; and we know how at Delphi and other places a fair was held almost every year. In modern Europe they appear to have been associated with the church festivals, which were found to afford convenient opportunities for commercial transactions, the concourse of people being such as took place upon no other occasion. This origin of fairs is commemorated in their German name *Messe*—i.e. 'mass' (compare the *-mas*, for 'mass,' in such words as *Lanmas*, *Martimmas*, &c.) Some festivals, from circumstances of place and season, speedily acquired a much greater commercial importance than others, and began, therefore, to be frequented by buyers and sellers even from remote parts of the world. When the ordinary means of communication between countries and opportunities for the exchange of commodities were very limited, fairs were of great use. Princes and the magistrates of free cities found it to their advantage to encourage them, and many privileges were granted, which in some places still survive. Courts of summary jurisdiction—commonly called in English 'pie-powder' (Fr. *piec potoir*), from the dusty feet of the suitors—were established distinct from the ordinary courts of the county or city, for the determination of questions which might arise during the fair. In connection with all this the practice was necessarily adopted of publicly proclaiming the commencement and duration of the fair, and this still subsists where scarcely any other vestige remains of the old privileges of fairs.

In western Europe the goods exposed for sale at fairs are chiefly those in respect of which there is a frequent change of fashion. While in some parts of the Continent persons of all ranks still wait for the great yearly fairs to make their principal purchases of clothing and of manufactured articles of every description, such things as corn,

wine, spirits, tea, coffee, sugar, tobacco, oil, &c. are seldom seen in them. It is otherwise, however, in places on the outskirts of civilisation; and almost all the produce of great provinces is sold, and all that their inhabitants require is bought, at such fairs as those of Kiakhta and Nijni-Novgorod. In France much of the European commerce of the middle ages was transacted at the famous fairs of Champagne and Brue, where the merchants of Italy, Spain, and France congregated. The British fairs really of much use at the present day are those at which horses and live-stock are exposed for sale, and even these have greatly decayed in importance: of these some held on the borders of the Scottish Highlands and elsewhere in Scotland were wont to be frequented by buyers and sellers from all parts of the kingdom. Such are the fairs or trysts, as they are called, at Falkirk, Doune, &c. At other great yearly fairs in the south of Scotland lambs and wool are sold; and fairs chiefly for the sale of the annual produce of pastoral districts are common in almost all parts of the world.

Of the three annual fairs at Leipzig the most important are the Easter and Michaelmas fairs, each of which lasts three weeks. The chief articles sold are leather, cloth, and furs. The Leipzig Book-fair is a fair in name only, being really an occasion for the settlement of accounts among booksellers and publishers; it occurs at the time of the Easter fair. Next to the Leipzig fairs those of Frankfort-on-Maine are the most important in Germany. The great fairs of Beaucaire in France, of Frankfort-on-Maine and Frankfort-on-the-Oder in Germany, of Pesth and Debreczin in Hungary, of Sinigaglia, Alessandria, and Bergamo in Italy, and of Nijni-Novgorod (q.v.) in Russia are among the most important in Europe; the last, which attracts representatives from all parts of the Russian empire, occupying a site comprising 7 sq. miles. The fairs of Tanta in Upper Egypt, of Kiakhta and Irbit in Siberia, of Mecca in Arabia, and of Huidwar in Western India are also of very great importance. That of Kiakhta is a sort of barter-market, where almost all the commercial transactions between the Russian and Chinese empires take place. The fairs in Britain have latterly sunk for the most part to insignificance, and in many instances have entirely disappeared. They were gatherings adapted to a comparatively backward state of society, when the provincial stores of goods were few, and the means of communication defective. The prevalence of good roads, populous towns with dealers in miscellaneous wares, and improved methods of transport have superseded the necessity for the ordinary class of fairs, and in consequence they have in some cases degenerated into mere scenes of merriment. Such were Bartholomew Fair (q.v.), Greenwich Fair, Glasgow Fair, and Doneybrook Fair, near Dublin; all either extinct or nearly so. The boisterous merriments at these fairs were of old the devices employed as likely to attract a great concourse of people; hence each fair had its sport or drollery—football, wrestling, yawning, cudgel-playing, throwing at coeks, sack-races, flying dragons, grinning through horse-collars, mock-giants, monstrous fishes, soaped pigs, smoking-matches, eating hot hasty-pudding, whistling, wheelbarrow races. At Stourbridge Fair, one of the most important in the kingdom, an excellent proclamation was issued in 1548 by the university of Cambridge in 'erying the fair,' containing among other 'comandments' this clause: 'No brewer sell into the fayer . . . a barrell of good ale above two shillings—no long ale, no red ale, no soppie ale, but good and halsome for man's body, under ye payne of forfeiture.' It has been remarked that fairs were

established for the most part on the frontiers of the kingdom, or on the marches of ancient provinces; or at the foot of high mountains, at the beginning or end of the snow-season, which for months shuts up the inhabitants in their valleys; or in the neighbourhood of famous cathedrals or churches frequented by flocks of pilgrims; or in the middle of rich pastures. A fair at Christ's Kirk, in Aberdeenshire, held in May, when the nights are very short, began at sunset, and ended an hour after sunrise: it was called 'Sleepy Market.' In America the word fair is used rather for what would in England be called an industrial exhibition, bazaar, or 'fancy fair.' See Cornelius Walford's *Fairs, Past and Present* (1883).

**Fair Trade.** See FREE TRADE.

**Fairy Rings** are spots or circles in pastures, which are either more bare than the rest of the field, or more green and luxuriant. Frequently a bare ring appears, like a footpath, with green grass in the centre, and the circle which the ring forms, or of which it might form a part, is often some yards in diameter. Apart from supernatural hypotheses, it was sometimes imagined that they might be the effect of lightning. Dr Withering appears to have been the first, in 1796, to ascribe them to the growth of fungi; and they are now known to be due to the outwardly spreading growth of the perennial subterranean mycelium of various fungi, chiefly species of *Agaricus*, even the Common Mushroom (*A. campestris*) showing a tendency to grow in the same manner. The spot where the agaric has already grown is unfitted for its continued nourishment, and the mycelium (spawn) extends outwards to new soil, the fungus exhausting the soil to which it extends for the immediate nourishment of grass, but enriching it afterwards by the highly stimulating products of its own decay. Fairy rings of large size sometimes occupy the same situation for many years. The circle is almost always imperfect, some accidental obstacle having broken the completeness of the expanding ring of mycelium.

**Faith** is used by theologians in various senses. It is sometimes taken to denote the mere assent of the understanding to a set of facts or of propositions set before it; but it is more peculiarly used to express the living reception by the heart of the 'truth as it is in Christ.' Some divines have enumerated no fewer than four kinds of faith: (1) The faith of miracles, or that immediate persuasion of the almighty presence and power of their Master, which enabled the early Christians to work miracles—a persuasion, apparently, which might exist and issue in astonishing results without being associated with moral excellence. 'Though I have all faith,' says St Paul, 'so that I could remove mountains, and have not charity, I am nothing.' (2) Historical faith, or the assent of the understanding to truth, the evidence of which is irresistible, such as we have described above. (3) Partial or temporary faith, such as our Lord implies in his exposition of the parable of the Sower, and as appeared to animate those who, after having followed after Christ, turned back and walked no more with him; and (4) Saving faith, or the persuasion of Christian truth wrought in the heart by the Holy Spirit.

These distinctions are rather theological refinements than anything else; the proper and characteristic meaning of the term faith in Scripture has little to do with any of them except the last. 'Faith,' says the writer of the Epistle to the Hebrews, 'is the substance of things hoped for, the evidence of things not seen.' It is a vision, quality, or capacity of soul whereby spiritual truth is apprehended, and spiritual life engendered. The

distant is brought near by it, and substantially appropriated; the unseen is felt to be a reality. Faith is the organ by which the soul passes beyond the present and the visible to the eternal and the invisible. Still more characteristically, perhaps, faith is the living affection which binds the Christian to Christ as a *Saviour*.

Faith, in the distinctively Christian sense, can only exist by the operation of God's Holy Spirit. 'For by grace are ye saved, through faith; and that not of yourselves; it is the gift of God.' Orthodox divines greatly insist on the necessity of this operation of the Spirit of God, yet not so as to exclude the active co-operation of man. The Pelagian and Antinomian extremes respectively throw out—the former the divine, the latter the human element. Orthodoxy combines the two, attributing to God the effective agency, but to man a real and voluntary concurrence. For the theological controversies connected with faith, reference must be made to the theological treatises of the different communions. See also JUSTIFICATION.

**Faithfull**, EMILY, born at Headley Rectory, Surrey, in 1835, early became interested in the condition of working-women, and in 1860 founded in London a printing establishment where women were employed as compositors. The Queen marked her approval of the work by appointing Miss Faithfull printer and publisher in ordinary to Her Majesty. In 1863 she started the *Victoria Magazine*, in which the claims of women to remunerative employment were set forth; and in 1868 she published *Change upon Change*, a novel. Shortly after, she appeared as a lecturer, and in 1872-73 first visited the United States in this capacity (see *Three Visits to America*, 1884). In 1889 she was awarded a civil list pension of £50.

**Faith-healing**, a system of belief based on James, v. 14, that sickness may be treated without any medical advice or appliances, if the prayer of Christians be accompanied in the sufferer by true faith. Dorothea Trudel, at Mannendorf in Switzerland, is said to have wrought marvellous cures by faith and prayer alone between 1850 and 1860; but the recent movement in favour of faith-healing, which is especially conspicuous in Sweden and in the United States, is mainly the outcome of the success attained by Pastor Blumhardt, who began a similar system of cure at Möttingen, in Württemberg. He ultimately resigned his charge, and bought a property with a sulphurous mineral spring at Boll, near Göppingen, where his system was fully developed in a large and much-frequented building specially arranged for his patients. He died in 1880, aged seventy-five. See his *Life* by Zündel (2d ed. Zurich, 1881). There are homes for faith-healing, called *Bethshams* (Heb., 'house of rest'), at various places in Britain and the United States. Some diversity obtains amongst believers whether the cures are to be accounted miraculous or not, and whether, in addition to the laying on of hands, anointing with oil should be practised. See PECULIAR PEOPLE.

**Faithorne**, WILLIAM (1616-91), English engraver, whose works were catalogued by Fagan in 1888. See ENGRAVING, p. 379.

**Faizabad**, the capital of the central Asian state of Badakhshan (q.v.), stands on the Kokcha, a tributary of the Amu-Daria, 180 miles N.E. of Kabul. It is noted for the rubies found near it.—For the Indian town of this name, see FYZABAD.

**Faizpur**, a town of Bombay presidency, about 200 miles E. of Surat, with a reputation for its dark-blue and red dyes and cotton prints. Pop. 9640.

**Fakir**, an Arabic word meaning 'indigent' (not to be confused with *fakih*, vulgarly pronounced

*fiki*, 'a pedagogue'), and commonly used to designate a member of an order of mendicants or penitents, chiefly in India and the neighbouring countries. In Persia and Turkey the word is also synonymous with Dervish (q.v.), and in Egypt is particularly assigned to that class of dervishes which performs *zikrs* and chants funeral dirges. The origin of Fakrism, an institution which reaches back to the most remote antiquity, is lost in mythical darkness. The common account of the son of a mighty raja, who, expelled from his home and country by the cruelty of his father, made a vow, half in revenge and half in contrition, henceforth to roam a beggar through the world, and to win proselytes to a life of poverty and self-mortification, as most befitting man and most pleasing to the Deity, can hardly be called historical. The same yearning for rest, for peace and pious contemplation, for escape from the noise and turbulence of the world, has everywhere and always led pensive minds into retirement and solitude; and constant seclusion and ceaseless meditation in India, as elsewhere, produced in all but exceptional minds their sad results. Thus abstinence became mortification and self-torture; mental repose was turned to mystic self-absorption or frenzied exaltation. This leaning of the Hindus to a life of asceticism was fostered by their religion, which enjoins various exercises of penance and mortification upon the three higher castes in general, but upon the Brahmins in particular. The world and its usages have no more any claim upon them; even religious ceremonies are no longer necessary to the 'United with God.' They go naked, or in filthy rags, receive the meanest food only, and that without either demand or thanks. Their ethical code consists in the observance of truth, chastity, internal purity, constant repentance, and contemplation of Deity. Fakrism seems chiefly to have been framed upon this phase of Brahminism, and its adherents were not only pious men, but occasionally saints, believed to be workers of 'miracles' and healers of all ills, especially epilepsy and sterility. But the halo which from the first surrounded Fakrism, and the ready homage offered by the people, attracted to its ranks at a very early date many whose motives were anything but pure, and who under a garb of humility and mendicancy collected fabulous treasures. Strabo already distinguishes these vagabonds from the more honest members of their class, and, if we may trust the travellers of our own day, the more respectable element has now altogether disappeared. Their number is variously stated. In the time of Tavernier's visits (1643-69) there were more than 1,200,000 Hindu and 800,000 Mohammedan fakirs in the East Indies, and their present number is said to exceed 3,000,000. At times, especially on their return from distant pilgrimages, they are even dangerous, as the killing of an unbeliever is supposed to be an infallible introduction to the glories of paradise. They live either separately as hermits or solitary mendicants, or unite in large gangs, carrying arms and a banner, beating drums, and sounding horns as they approach a town or village. Their appearance is often disgusting in the extreme; they go naked, besmeared with the dung of the holy animal, the cow. Some bedeck themselves with the skins of serpents, some with human bones; others array themselves in the garb of women. Their fearful shrieks, and the rollings of their eyes, add to the hideousness of their appearance. Imitating madmen, they generally end by becoming madmen. Some pass their whole lives in iron cages, laden with heavy chains; some clench their fists till their nails grow through the hand; others hold aloft both their arms till they become like withered branches; while others, again, tie their hands and feet together, and roll head over heels for long distances—for

thousands of miles in some cases, it is said. Not the least sad feature in all this is that these religious antics are not confined to men, but that youths and even children of tender age are occasionally initiated therein. See, among other works, the *Qanoon-e-Islam*, trans. by Herklots (1832). Some forms of Christian Asceticism (q.v.) have produced types, such as Simeon Stylites (q.v.), worthy to be compared with Mohammedan fakirs.

**Falaise**, a town in the French department of Calvados, on the Ante, a feeder of the Dives, 23 miles (by rail 31) SSE. of Caen. Crowning a rocky platform, with steep cliff or *falaise*, stands the noble ruined castle once the seat of the dukes of Normandy, and the birthplace of William the Conqueror. Its donjon keep is Norman, whilst 'Talbot's' Tower is supposed to have been built by Talbot, after the capture of Falaise by Henry V. of England. The town has manufactures of cottons, hosiery, and bobbin-net, and dye and tan works. At the large suburb of Guibray an important horse-fair, established by the Conqueror, is held in August. Pop. 8276.

**Falashas**. See ABYSSINIA.

**Falcón**, a maritime state of Venezuela, on both sides of the Gulf of Maracaibo, and separated from Colombia by the barren Sierra de Perijá (4125 feet). In the west the country is full of wooded hills; elsewhere the surface is generally level, the coasts are flat, and the fertile but unhealthy plain to the south of the gulf is covered with lakes and swamps. It contains coal, and exports goat-skins, coffee, cacao, sugar, castor-oil, tobacco, agave-rum, pistachio-nuts, dyc-woods, and timber. The chief towns are Maracaibo and Coro (q.v.). Pop. (1886) 198,260.

**Falcon** (*Falco*), the crowning genus in the family Falconidae, including numerous species which excel even the eagles as birds of prey. They are represented in all parts of the world except the South Sea Islands, and are almost always distinguished by their carnivorous habit, active life, and that evolved hunting talent which has led to the frequent use of not a few forms in the sport of Falconry (q.v.). The beak is short and strong, with a sharp-hooked point and an upper tooth fitting into a depression in the lower half; the claws are strong and sharp, and the outer toe is rather longer than the inner; the lower part of the leg is covered with a net-like pattern of scales; the regions round about the keen eyes are bare; the wings are long and pointed; the tail is also long and rounded. The falcons are pre-eminent for boldness, keen sight, and muscular power. One is said to have traversed the distance between Fontainebleau and Malta, not less than 1350 miles, in 24 hours; and the speed attained when in pursuit of prey has been estimated at 150 miles an hour. They are able to soar to an immense height, and always endeavour to get above the bird they wish to strike. The distinctness of the various falcons is much disputed by experts; the fivefold grouping here followed is that adopted by Professor A. Newton.

(1) The cosmopolitan Peregrine Falcon (*F. peregrinus* or *communis*) was formerly a firmly established British species, but, though still persisting in some parts, has suffered enormously from unreasonable persecution. It is a powerful bird, though only about 16 inches long, and is brave and masterly in its hunting. In colour the adult is blackish-brown to grayish-blue above, and whitish, with a reddish shade, beneath. Especially on the lighter under surface are seen the dark bars, which in this and the gyrfalcons are longitudinal before and transverse after the first moult. The female is larger and more powerful than the male, with a

slightly longer body, and decidedly longer wings; she is the 'falcon' of the falconers, the male is a 'tiercel,' the more rufous young forms are 'red falcons' or 'red tiercels.' The peregrine preys upon flying birds, such as wood-pigeons, all sorts of grouse, partridges, and plovers, or by the seashore on puffins, auks, and other marine birds. The falconers pit them against herons, and on its own account a falcon has been known to attack an intruding eagle. The cogent argument used against exterminators of falcons is that which may be urged against any disturbance of the balance of nature: that they kill grouse, pheasants, and other game-birds is undoubted, but they naturally tend to weed out the weaker forms, and thus, unless they predominate unduly, do more good than harm. Some even regard the grouse disease as a nemesis of the destruction of the nobler falcons. Peregrines usually live in pairs, and build large nests, generally of sticks and herbage, on very varying sites—sea-cliffs, inland rocks, or even trees. The Australian Peregrine (*F. melanogenys*) and the North American form (*F. anatum*) are probably only varieties of the above species.

(2) Next come a number of northern gyrfalcons, like the preceding, formerly much used in falconry. The Scandinavian Gyrfalcon (*F. gyrfalco*), which sometimes wanders farther south, and has been seen wild in Britain; the Icelandic (*F. islandus*), which also comes to Britain; the nearly pure white Greenland Falcon (*F. candicans*), of which the migratory Greenland Falcon (*Falco candicans*), ing young have been seen in Britain; and the North American Gyrfalcon (*F. labradorus*) are important forms. In their native haunts they feed on ptarmigan, geese, and other such birds.

(3) Somewhat distinct are the desert falcons, by some authorities distinguished as the 'lanners' (*F. tinnuncius*) and 'sakers' (*F. sacer*) of south-eastern Europe, North Africa, and south-western Asia, both used in falconry.

(4) The Merlin (*F. aesalon*) is a British species, like the peregrine in process of extermination. The male is bluish above and rather ruddy beneath. It is decidedly smaller than the peregrine, and preys upon smaller birds, such as finches, larks, and thrushes; yet so bold is it that it has been known to turn threateningly upon man.

(5) The English Hobby (*F. subbuteo*), with upright carriage and long wings, is a summer visitor in Britain, an eager enemy of larks, and sometimes even condescending to eat insects. Both of the last species have been used in British falconry. The Kestrel (*Tinnunculus*) is a nearly allied genus, separately discussed.

**Falcone**, ANIELLO, Italian battle-painter, born at Naples in 1600. He studied under Ribera (Lo Spagnoletto), and subsequently founded a school of painters at Naples. During Masaniello's outbreak (1647) he organised his scholars and dependents into a secret band (Compagnia della Morte) for assassinating Spaniards at night. On

the suppression of the insurrection Falcone betook himself to France, but subsequently returned to Naples, where he died in 1665. His works, few in number, represent chiefly military scenes.

**Falconer**, HUGH, an eminent botanist and palaeontologist, was born at Forres in Elginshire, 29th February 1808. He graduated M.A. at Aberdeen in 1826, and M.D. at Edinburgh in 1829, and joined the medical service in Bengal of the East India Company. Appointed in 1832 keeper of the botanic garden at Sahāraipur, he distinguished himself by the discovery of a large number of fossils in the tertiary deposits of the Siwālik hills. It was under his care that the first experiments were made by government in the growth of tea in India; and it was he who discovered during a journey in Cashmere the *asafoetida* plant of commerce. Overwork told upon his health, and in 1842 he had to return to England, whither he carried five tons of fossil bones and seventy large chests of dried plants. In England Falconer devoted himself to writing memoirs and papers on Indian botany and palaeontology, to arranging the Indian fossils in the British Museum and East India House, and to preparing his great illustrated folio, *Fauna Antiqua Silvalensis* (parts i.-ix. 1846-49). He returned to India in 1847 to become superintendent of the botanic garden and professor of Botany in the Medical College at Calcutta. He came home finally in 1855, and in spite of failing health continued his palaeontological studies with heroic energy. He died in London, 31st July 1865. A fund of £2000 was raised to provide a memorial of this devoted martyr to science. A memorial fellowship was also founded at Edinburgh University to promote the study of palaeontology and geology. The *Palaeontological Memoirs and Notes of the late Hugh Falconer* were published in 1868.

**Falconer**, THE HON. ION KERR, Orientalist, missionary, and athlete, was the third son of the Earl of Kintore, and was born in Edinburgh, 5th July 1856. From Harrow he went to Cambridge, and there he began evangelistic work, continued in conjunction with Mr Charrington at Mile End Road, London. Here he aided by personal effort in founding an assembly hall, to which he contributed £2000. A keen cyclist, he defeated the then fastest rider in the world (1878), and rode from Land's End to John o' Groat's. He had accepted the Lord Almoner's professorship of Arabic at Cambridge, and was settled at Shaikh Othman, near Aden, as a missionary under the auspices of the Free Church, when his bright and promising career was cut short by fever, May 10, 1887. He was author of the article 'Shorthand' in the *Encyclopædia Britannica*, and in 1885 translated the Fables of Bidpai (q.v.), with an admirable introduction. See *Memorials of Keith-Falconer*, by the Rev. Robert Sinker (Camb. 1888).

**Falconer**, WILLIAM, poet, was born in Edinburgh on 11th February 1732. A barber's son, he went early to sea, and before he was eighteen years of age was shipwrecked off Cape Colonna in Greece. The incidents of this voyage and its disastrous end form the subject of Falconer's principal work, the poem entitled *The Shipwreck* (1762). He then entered the royal navy, being appointed towards the end of 1769 purser on the *Aurora* frigate, which foundered at sea, with all hands, shortly after 27th December, the day on which she left Capetown. Falconer wrote several poems, but *The Shipwreck* is the one on which his fame rests; it went through three editions during its author's lifetime. His *Demagogue* is a satire on Wilkes and Churchill (1764), and he was also author of the *Universal Marine Dictionary* (1769).

**Falconet**, a name used in the 15th and 16th centuries for a small field-gun. The ball weighed from 1 to 2 lb., and the gun from 5 to 15 cwt.

**Falconidae**, a large family of Birds of Prey (q.v.), occupying a position similar to that of

Felidae among Carnivores. The unsenlar strength and power of flight; the habit of preying upon living animals, and that in daylight; the world-wide representation by over 300 species, are to be noted. The beak is rather short, but very strong, and highest at the root; the partition between the nostrils is complete; the upper margin of the eye-socket projects; the feet bear

Head and Foot of Brazilian Eagle.

strong, sharp, bending claws and large sole-pads. The family includes the Falcons *par excellence*—e.g. the genus *Falco*; the Eagles—e.g. *Aquila*, *Haliaeetus*; the Buzzards—e.g. *Buteo*; the Kites—e.g. *Milvus*, *Elanus*; the Hawks—e.g. *Nisus*, *Accipiter*; the Harriers—e.g. *Circus*; the Caracaras—e.g. *Myieter*, *Polyborus*—for which see the separate articles.

**Falconry** (from Old Fr. *falconnerie*, a term introduced by the Normans), the art of training falcons and hawks to the chase. The term hawking (from M.E. *hawk*, earlier *hurek*—i.e. *hurek*, and A.S. *hafoc*), though often used synonymously, is more correctly restricted to the practice of this art in the field. In the East falconry has been traced back to a period anterior to the Christian era, and was practised there and also in Europe long before its introduction into Britain. It was known to our Saxon ancestors, and is mentioned in the *Colloquy* of Archbishop Ælfric, written in the 10th century. In the celebrated Bayeux tapestry Harold is represented with a hawk upon his glove; and the Norman nobles, who were as much addicted to hawking as to hunting, gave a great impetus to the sport in England by the importation of falcons (especially jervfalcons) from abroad, and by the large sums they expended upon this diversion. Henry II. used to send every year for young falcons from the cliffs of Pembrokeshire. Richard I. while in the Holy Land amused himself with hawking at Jaffa, in the plain of Sharon, with hawks which he had brought with him from England. King John used to send to Ireland for his hawks—amongst other places to Carrickfergus, County Antrim, and was especially fond of a flight at the crane with jervfalcons which he received from the king of Norway. He used to hawk in Dorsetshire and Somersetshire, as appears by entries in the court rolls of payments for the expenses of the journeys. When Edward III. invaded France, he had with him, according to Froissart, thirty falcons, and every day either hunted or hawked as his fancy inclined him. The Paston Letters, written in the reign of Edward IV., give an insight into the ways and doings of English falconers in the middle ages, as do also the various 'Household Books' which have come down to us. Henry VII. used to import his goshawks from France, and Henry VIII.'s love of the sport nearly

cost him his life, if we may believe the anecdote told of him in Hall's *Chronicle*. During the reign of Elizabeth hawking was much in vogue in England, and Nichols in his *Progresses* has given some interesting details of the queen's participation in this pastime. James I. was a most enthusiastic sportsman, and gave a great impulse to hunting and hawking in England by inviting those of the French nobility who were the greatest adepts in these field-sports to come over to this country, and compete in friendly rivalry with his own subjects. He was especially fond of kite-hawking with jerrfalcons, and carried this branch of the sport to great perfection on the wide heath of Royston, Newmarket, and Thetford. It may be well to correct here an erroneous statement which has been many times repeated in print to the effect that Sir Thomas Monson in the reign of James I. gave £1000 for a *cast*—i.e. for two hawks, the truth being (as stated by Sir Antony Weldon in his *Court and Character of King James*, 1650) that he spent £1000 before he succeeded in obtaining a cast which he considered perfect for kite-hawking.

These were the palmy days of falconry, when the sovereigns on both sides of the Channel (James I. and Louis XIII.) were enthusiastic falconers, giving every encouragement to the sport, when the species of hawk carried was indicative of the rank of the owner, and when the best books were written by English and French masters of the craft.

The disastrous state of the country during the period of the civil wars naturally put an end for the time being to the general indulgence in field-sports; and it may be said that at the Restoration hawking had ceased to be popular, although from that time until the present it has never ceased to be practised by a few admirers of the old sport in various parts of the country. The last member of the royal family, it is believed, who sent for or received hawks from abroad was Frederick, Prince of Wales, son of George II., who occupied the 'palace of Durdans' at Epsom, now a seat of the Earl of Rosebery's, and used to hawk over the downs, where in 1825 there was a spot still known as 'the Hawker's.' Fashion, no doubt, had a good deal to do with the decline of hawking, for so soon as the reigning sovereign ceased to take an interest in the sport the courtiers and their friends followed suit. Between the years 1751 and 1791 the third Lord Orford did much to encourage the practice of falconry in England; and during the first quarter of the 19th century Colonel Wilson (afterwards Lord Berners) in Norfolk, and Colonel Thornton, of Thornville Royal in Yorkshire, not only practised game-hawking with great success (as did also Sir John Sebright, who wrote a practical treatise on the subject in 1826), but excelled in those higher branches of the sport, kite-hawking and heron-hawking, which have long since become impracticable by reason of the extinction of the former quarry and the impossibility of securing the requisite conditions for a flight at the latter.

In 1840 the formation of the Loo Hawking Club, whose headquarters were at the summer palace of the king of Holland, kept the sport alive for many years, and several English falconers who kept hawks of their own annually repaired to Loo for the enjoyment of heron-hawking, which was there carried out to perfection by the Dutch falconers Van der Heuvel, the brothers Bots, and the veteran Adrien Mollen. The last owner of heron-hawks in England was Mr Edward Clough Newcome, of Hoekwold in Norfolk, a most accomplished falconer, who died in 1871. About this time was formed the Old Hawking Club, which

still flourishes, and annually pursues the sport of rook-hawking in the spring and game-hawking in the autumn, the interval being devoted to lark-hawking with merlins and flights with the goshawk at rabbits and hares. Of late years the taste for falconry has manifestly increased, and there are now a great many owners of hawks (besides the members of the club just named) who carry on the old sport with more or less success in different parts of the United Kingdom. It may therefore be said that, although from various causes hawking in England has declined since the days of the Stuarts, it has never actually died out, and is even at the present day in a fair way to be thoroughly revived.

The birds employed by falconers belong to two classes—the long-winged, dark-eyed falcons, and the short-winged, yellow-eyed hawks. To the former class belong the Jerrfalcons, Peregrine, Lanner, Saker, Barbary Falcon, the Indian Shahin, the Hobby, and the Merlin; to the latter the Goshawk and Sparrow-hawk. The former take their prey by rising above it in the air, and *stooping* at it from a considerable height, and striking it to the ground; the latter pursue in a straight line, and overtaking the quarry by superior speed, clutch it, and come down with it. The larger falcons are flown at winged game of all kinds—crows, magpies, rooks, herons, and wild-fowl; the smaller falcons, such as the merlin and hobby, are used for taking larks; while of the short-winged hawks the sparrow-hawk is flown at blackbirds and thrushes, partridges early in the season, and quails, the goshawk taking pheasants, partridges, and wild-fowl, rabbits and hares. With all birds of prey the females are invariably larger and more powerful than the males, and the sexes are consequently selected according to the quarry they have to pursue. Jerrfalcons are now rarely employed, partly owing to the difficulty of procuring them, partly because the peregrine falcon is preferred, and experience has shown that except in a woody or inclosed country, where the goshawk and sparrow-hawk are preferable, the peregrine is the most useful of all the birds of prey.

Hawks are either taken young from the nest before they can fly, when they are termed *eyesses*, or are caught later, during the period of their migration, by means of a decoy-pigeon and a bow-net, when they are called *passage-hawks*. The mode of treatment is a little different, inasmuch as the latter have already learned to catch and kill prey for themselves, and only require to be tamed; the former have everything to learn. A passage-hawk on being caught is hooded, and has jesses, or soft leather straps, fastened on her legs. She is then set down on a block of turf to prevent damage to feathers, and fed once a day, at first through the opening of the hood, afterwards with the hood removed. The bird is always fed upon the gloved hand, and gradually learns to step on to it from the perch, increasing the distance daily until she is obliged to fly to reach the fist. The training then commences. The hawk is *called off*, as it is termed, *to the lure*, which means that after tying a long line to the ends of the jesses she is held hooded on the hand of an assistant, until the falconer at the distance of five-and-twenty yards swings the lure to which the bird has been accustomed to come to be fed. The hood being then removed, the hawk flies to the lure, and is exercised in this way for some time daily, until she is sufficiently tractable to be trusted without a line, care being taken not to feed her until she has flown, and always to reward her for coming to the lure with a morsel of the meat with which it is garnished. She is then *entered at the quarry* at which she is intended to be flown (partridge, rook, or whatever it may be)

by first giving her a live bird at the end of a long line, and allowing her to go off the fist and kill it; eventually the line is dispensed with, and she is flown at wild quarry.

Such, briefly, is the mode of training a passage hawk. An eyess is somewhat differently treated. A straw-covered platform is put up in some shed or outhouse, and on this the nestlings (which should not be taken too young, or they will turn out *screamers*) are placed, the platform being about as high up as one can reach to feed the birds. They are fed three times a day on fresh lean beef, while growing, to keep up their strength, or *hunger-traces* will appear, like cuts across the webs of the feathers, and the latter breaking will render the birds useless. When they are strong enough and

Fig. 1.—Leg and foot of Hawk, showing the method of attaching the jesses and bell:

a, end of the leash; b, jesses; c, the bell; d, bewit; e, varvets.

able to fly, jesses are put on the legs, and a spherical brass bell (of Dutch or Indian make) on one leg, fastened just above the *jess* with a little narrow strip of leather termed a *bewit* (see fig. 1). At feeding time, now once a day, they are called to the lure, and, being allowed their liberty for some

weeks (in which state they are said to be *flying at hawk*), they daily gain strength and wing-power, until the time comes for taking them up and commencing their training, which after this stage does not differ much from the method above described for passage-hawks. When flying at hawk, a hawk sometimes becomes wild, wanders away to a distance, and kills game for herself. When this is perceived, a bow-net, or other device for snaring, is set for her, to which she is decoyed and recaptured.

The first operation in training is *hooding*, which, if successfully performed, overcomes much difficulty. It requires some patience and dexterity, and should be practised at first in a darkened room, in which the hawk will be much quieter than in broad daylight. The hood is simply a cap of leather (see fig. 2) made to fit the head in such a

Fig. 2.—Hooded Peregrine on the block:

One end of the leash is attached to the jesses, the other to a ring driven into the side or top of the block; and thus the hawk is prevented from escaping.

manner as to obscure the light, a single aperture only being left, through which the beak protrudes,

and a slit behind, which is opened and closed, when the hood is put on and off, by means of *braces*, one pair of which opens, the other pair closes the slit; the eye-pieces, which to prevent injury to the eyes are carefully *blocked out*, are covered for ornament with red or green cloth. By temporarily blindfolding the hawk, the hood causes her to sit perfectly quiet, and prevents her from *bating*, or fluttering, at the risk of breaking feathers, as she would do if frightened by passers-by until gradually accustomed to them.

Allusion has already been made to the jesses, or soft straps of leather (dog-skin is best), which are fastened to the legs of the hawk, by which to hold her on the glove and tie her to the perch or block. These jesses are about 6 inches long, and are never removed when the hawk is flown. In former times *varvets*, or flat rings of silver with the owner's name engraved thereon, were permanently attached to the ends of the jesses, and through these one end of the leash was passed, the other end being prevented from going through by a leather button. At the present day, however, most falconers prefer using a figure-8 swivel, which is always detached before the hawk is flown.

The *lure*, already referred to, is a device for luring the hawk back to her owner after an unsuccessful flight, and on this account the hawk is early made acquainted with it by being fed upon it daily while being trained. There are various patterns; one of the simplest and most easily made consists of a couple of pigeons' wings tied together on a flat circular leaden weight covered with leather, upon which a piece of raw meat is tied on both sides. The *tabur-stick* and *draver*, which were formerly used as lures, have long been discarded.

The beaks and claws of wild caught hawks are generally so long and sharp as to require *paring* or *coping*, as it is termed; but this operation requires to be very carefully performed (the hawk being hooded and held by an assistant), and not more than the tenth of an inch removed, or the efficiency of the beak and claws will be impaired. Indeed some falconers will never cope a hawk, except when the beak is overgrown; and with goshawks especially, which have to hold such powerful prey as hares and rabbits, strong and sharp talons are indispensable.

Eastern falconers carry their hawks upon the right hand; but European falconers always carry them on the left, leaving the right hand free for detaching leash and swivel, and removing and replacing the hood.

The following are some of the technical terms used in falconry. The wings of a hawk are termed the *sails*; the tail, the *train*; the legs, *arms*; the toes, *petty singles*; the claws, *pounces*; the crop, *gorge*; the stomach, *panel*; the pellets of feathers and indigested food which are thrown up after feeding are termed *castings*. A young hawk from the nest is an *eyess*; one that can perch but not fly, a *brancher*; an eyess reared at liberty, a *hack-hawk*; one taken later on migration, a *passage-hawk*; a young hawk in the first year's plumage is called a *red-hawk*, or a *sour*- or *sore-hawk*, from the Fr. *sorel*, 'a reddish-brown colour.' A wild caught adult hawk is a *haggard*. After the first moult a hawk is said to be *intermeved*; when completely moulted, *full stemmed*; when purged of all superfluous fat and in good condition, *enseamed*. A broken feather is repaired by a process termed *imping*; cutting or paring the beak and claws is termed *coping*. The prey when living is called the *quarry* (from the Fr. *curée*); when dead, the *pelt*. A hawk is flown either *out of the hood*—i.e. off the fist—as in rook-hawking, or is *put up*, or *cast off*, as in game-hawking before the game is sprung.

In the latter case, when a hawk soars in circles at a height above the falconer's head, she is said to *wait on*. She *stoops* when descending with closed wings from a height at the quarry, *binds* when she seizes it in the air and comes down with it, *carries* when she flies off with it, *rakes off* when she flies straight away without soaring, and *checks* when she changes the bird in pursuit. At home she sits either indoors upon the *perch* or out of doors upon the *block*, and is carried to the field hooded upon the *cadge*, a padded wooden frame of square or oval shape, which is borne by an assistant with the aid of shoulder-straps. In this way six or eight hawks may be carried without difficulty, since, being hooded, they sit perfectly quiet.

The principal works on falconry in English are the treatise on hawking in *The Boke of St Albans* (1486) of Dame Juliana Berners (q.v.), from which very little practical instruction is to be gained; Gervase Markham's *Gentleman's Academie* (1595), a later version of the last named; Turberville's *Booke of Falconrie* (1575-1611); Latham's *Falcon's Lure and Cure* (1615-18 and 1633); Bert's *Approved Treatise of Hawks* (1619); Nicholas Cox, *The Gentleman's Recreation* (1674, and numerous later editions); John Ray's *Summary of Falconry* (1678); Campbell's *Treatise of Modern Falconry* (1773); Sir John Sebright's *Observations on Hawking* (1826); Belaney's *Treatise upon Falconry* (1841); Salvin and Brodrick, *Falconry in the British Isles* (1855 and 1873); Freeman and Salvin, *Falconry: its Claims, History, and Practice* (1859); Freeman's *Practical Falconry* (1869); Harting's *Essays on Sport* (1883); *Hints on the Management of Hawks* (1884); and *A Perfect Booke for keepinge of Sparre Hawkes or Goshawks, from the original MS. of 1575* (1886).

**Faldstool**, a small desk in churches in England at which the litany should be sung or said. The name is also given to a folding-stool used by Roman Catholic bishops and other prelates on certain occasions.

**Falémé**, one of the most important tributaries of the Senegal, rises in Futa-Jallon, and after flowing in a northerly direction joins the main stream above Bakel. About 120 miles above its mouth the Falémé is interrupted by rapids and waterfalls. Up to that point it is navigable for small steamers during two months of the year.

**Falerii**, a city of ancient Etruria, and the capital of the Falisci, was situated west of the Tiber, and north of Mount Socrate. After its capture and destruction by the Romans (241 B.C.), the inhabitants settled on a new site a few miles off. See ETRURIA.

**Falernian Wine**, so called from *Falernus Ager*, the district in which it was grown—and which lay in the northern portion of Campania, between the Massican Hills and the northern bank of the Volturnus—was one of the favourite wines of the Romans. It is described by Horace as, in his time, surpassing all other wines then in repute. In the time of Pliny, however, Falernian wine had already, owing to a want of care in its cultivation, begun to decline in quality.

**Faliero**, MARINO, Venetian general and doge, was born about the year 1274. At the siege of Zara, in 1346, he defeated an army of 80,000 Hungarians, and afterwards, whilst in command of the fleet, captured Capo d'Istria. Subsequently he became ambassador of the republic to Rome and Genoa. He was elected Doge of Venice in 1354. In the following year, being dissatisfied with the punishment inflicted by a patrician tribunal upon a young noble, Michele Steno, who had publicly insulted the youthful wife of the aged doge, Faliero conspired with the plebeians to assassinate the oligarchy and make himself supreme ruler of Venice. The conspiracy was, however, revealed on

the eve of its execution, and Faliero was arrested and beheaded on the 17th of April 1355. His fate forms the theme of tragedies by Byron and Swinburne.

**Falk**, ADALBERT, Prussian statesman, one of the foremost combatants in the *Kulturkampf* (the struggle between church and state in Germany), was born at Metzelkau, in Silesia, 10th August 1827. Educated for the law, he held various judicial and administrative posts in his native province, until he was appointed Minister of Public Worship and Education in 1872. In this capacity he was mainly instrumental in carrying the so-called May laws (because passed in May 1873, 1874, and 1875), aimed at the hierarchical supremacy of the Church of Rome, by limiting the influence of the clergy in the schools, by reorganising the seminaries for the training of teachers, and by defining in a stricter and more comprehensive manner the relations generally of the clergy to the state. When, however, Bismarck came to bid for the support of the clerical party, in order to carry out his later internal policy, Falk resigned in 1879. Thereafter he retired altogether from political life.

**Falkirk**, a town of Stirlingshire, finely situated on a rising-ground in the midst of a populous mineral and manufacturing district, and overlooking an expansive 'earse,' by rail is 3 miles SW. of its seaport Grangemouth, 22 N.E. of Glasgow, and 26 WNW. of Edinburgh. Including now the suburbs of Grahamston, Bainsford, Laureston, and Camelon, it was constituted a parliamentary burgh in 1832, and with Airdrie, Hamilton, Lanark, and Linlithgow returns one member. Its parish church—the *Eglais Bhrec*, *Varia Capella*, or *Fau* ('speckled') *Kirk* of chartularies and local tradition—was rebuilt in 1810. There are also the county buildings (1868), burgh buildings (1876), town-hall (the former corn exchange, 1839), an equestrian statue of Wellington (1834), a science and art school (1878), the Dollar Free Library (1888), and a cottage-hospital (1889). The famous cattle 'trysts' or fairs, where stock was annually sold to the value of £1,000,000, have been largely superseded by the weekly auctions. The iron manufacture is carried on busily at Carron (q.v.) and elsewhere. Pop. (1851) 8752; (1891) 17,807. At Falkirk on 22d July 1298 Edward I. inflicted a disastrous defeat on Wallace, and on 17th January 1746 Prince Charles Edward defeated Hawley. Antoninus' Wall (q.v.) is the chief antiquity.

**Falkland**, a royal burgh (since 1458) of Fife, at the north-eastern base of the steep East Lomond Hill (1471 feet), 22 miles north of Edinburgh. Nothing remains of the old castle of the Earls of Fife, in which David, Duke of Rothesay, was starved to death by the Regent Albany (1402); but there are extensive and stately remains, still partly habitable, of the later royal palace (*circa* 1450-1542), with singularly fine renaissance details. It was the death-place of James V., and has memories of almost all the other Stuart sovereigns. With the estate and a modern mansion (1844), it was purchased in 1888 by the Marquis of Bute. Pop. 1068. See Major W. Wood's *Historical Description of Falkland* (Kirkcaldy, 1888).

**Falkland**, LUCIUS CARY, VISCOUNT, was born most probably at Burford, Oxfordshire, in 1610, son of Sir Henry Cary, himself of literary tastes and a friend of Ben Jonson. His father, created Viscount Falkland in the Scottish peerage in 1620, was the well-meaning but unfortunate lord-deputy of Ireland from 1622 to 1629; his mother was learned in languages and in the Fathers, was an early friend of Chillingworth, and, while still a girl, became a convert to the Catholic faith, though she did not avow it for twenty years. Lucius went to Ireland with his

parents, and had his education at Trinity College, Dublin, succeeded to his maternal grandfather's property at nineteen, according to Clarendon, and soon after married, to his lasting happiness, Lettie, daughter of Sir Richard Morrison. But the marriage irritated his father, who had been ambitious of a more splendid match, and moreover seems to have been displeased at the descent of his father-in-law's property to his son. With that instinctive unselfishness, linked with impulsive temper, so characteristic of his nature, Lucius at once offered, but to no purpose, to give up all claim upon the estate; he next crossed to Holland to volunteer into the service of the young republic, but soon returned to devote himself to his studies, especially of Greek. His father's death in 1633 gave him the title, and for a time he lived with his mother and listened dutifully to all her anxious arguments for his conversion. But his rational temper could not find rest in her summary solution of his questionings, and ere long, guided by the resistless intellect of Chillingworth, he reached conclusions as alien, in their large tolerance, to Puritanism as to Papistry. He soon settled down in his house at Tew, in Oxfordshire, to a severe course of study, and to that *convivium philosophicum* or *convivium theologicum* which the loving pen of Clarendon thirty years after described with so peculiar a charm. Hither came constantly the brightest intellects of the university, but sixteen miles distant, as well as the poets and wits from London. In the group of closest intimacy Clarendon enumerated Sheldon, Morley, Hammond, Earle, and Chillingworth, and to these we may add John Hales and the historian himself—great writer and constant friend. There is hardly another picture in our literary history so attractive as that of this 'university in a purer air' under the oaks and limes of Tew, and of the Tuscan disputations there of Falkland, Hales, and Chillingworth, three friends united by so warm a friendship, yet unlike in everything save supremacy of intellect, littleness of stature, and largeness of charity. To this period belong Falkland's pleasing but not striking poems, which were edited by A. B. Grosart in 1871. His *Discourses of Infallibility*, and the longer *Reply to the Answer thereto*, are a truer index to what lay closest to his heart.

For some years high thinking entirely occupied Falkland's mind, but in 1639 we find him offering his sword for service against the Scots, and actually accompanying Essex's expedition as a volunteer. After his return he sat in the Short Parliament for Newport in the Isle of Wight, and was again returned to the Long Parliament for the same place. Here he distinguished himself by his ardour and eloquence in behalf of constitutional liberty, which he felt to be endangered by the high-handed absolutism of Laud and Strafford. Although his innate love of fairness and justice impelled him at first to demand delay in the impeachment of the latter until the charges made could be fully inquired into, he both spoke and voted with the majority on the third reading of the bill of attainder. He took the same part in the question of ship-money, and vigorously attacked the real illegalities of Finch, the Lord-keeper; but, though he assailed the bishops' claims to divine right, he refused to support the abolition of Episcopacy, while willing enough at first to exclude the bishops from the House of Lords. But the popular party moved too fast for his wise and temperate patriotism, and, in his alarm at the threatening domination of a no less intolerant Presbyterianism, he found himself compelled to resist the second Bishops Exclusion Bill.

At the commencement of 1642, after much persuasion, he accepted the secretaryship of state,

although he evidently mistrusted the character of the king, and had no share in the counsels of the queen and the inner party that really ruled his actions. It was characteristic of the man that he refused to make use of spies or to open letters; and, as was to be expected, we find him active in the last ineffectual efforts to bridge the ever-widening breach betwixt the Court and the Commons. When the inevitable war broke out he gave his sword loyally to the king, but his heart sank within him to see his much-loved country bleeding in civil strife. There is no more touching figure in our history than this large-hearted patriot in his last few months of life, so real yet romantic is the pathos that enshrines him. Already the shadow of death hung over him, and Clarendon tells us, in the most famous passage of the *History*, how, his cheerfulness and vivacity gone, and even his customary carefulness in his dress abandoned, 'sitting amongst his friends, often, after a deep silence and frequent sighs, he would, with a shrill and sad accent, ingeminate the words "Peace, peace," and would passionately profess that the very agony of the war, and the view of the calamities and desolation the kingdom did and must endure, took his sleep from him, and would shortly break his heart.' On the morning of the battle of Newbury, 20th September 1643, he knew that the hour for which he longed had come. He was cheerful beyond his wont, and put on clean linen as if for a banquet. Placing himself in the front rank of Sir John Byron's regiment, he rode forward to meet his death at a gap in the hedge where the enemy's bullets flew thickest. 'Thus fell that incomparable young man, in the four and thirtieth year of his age, having so much despatched the business of life that the oldest rarely attain to that immense knowledge, and the youngest enter not into the world with more innocence; and whosoever leads such a life need not care upon how short warning it be taken from him.'

See Clarendon, both in the *History* and the *Life*; also S. R. Gardiner's *History*. There is no better account of Falkland than that in chap. 3 (vol. i.) of Tulloch's *Rational Theology in England in the Seventeenth Century* (1872). See also the characteristically urbane yet irritating essay by Matthew Arnold (*Nineteenth Century*, March 1877), with the sufficient reply by Goldwin Smith (*Contemporary Review*, April 1877); and that by Lord Carnarvon in the *Fortnightly Review* for November 1882, based on his speech delivered at the unveiling of a granite memorial at Newbury, 9th September 1878.

**Falkland Islands**, a British colony in the South Atlantic, lying between 51° and 53° S. lat.

and 57° and 62° W. long., some 250 miles E. of Patagonia, with which they are geologically connected by a submarine plateau. The group consists of East Falkland and West Falkland, with

about 100 small islands, besides the dependency of South Georgia (q.v.). According to the most reliable measurement—that of Wisotzki—East Falkland, with the neighbouring islands, has an area of 2849 sq. m., and West Falkland, with the small islands near it, an area of 1990 sq. m. Many of the islands are occupied only by myriads of penguins, whence the title King of the Penguins sometimes bestowed on the governor of the Falklands. Pop. (1871) 811; (1887) 1843. The shores are deeply indented with bays and inlets, containing many good harbours; the surface is for the most part undulating (Mount Adam, the highest point, 2315 feet), with numerous small streams and lakes; there are no trees, nor is coal found, but peat is plentiful. The climate is healthy, resembling that of the Orkneys, but is characterised by severe gales and abundance of moisture. The average annual temperature was 34° in 1887; the average number of rainy days in the year is 240. Some wheat and flax are raised, but tussock grass and balsam bog are the principal vegetable products. The chief industry of the inhabitants is sheep-breeding. Wool, frozen meat, live sheep, tallow, skins, and hides are exported (principally to the United Kingdom). The exports rose from £20,000 in 1870 to £108,000 in 1887; the imports from £21,000 to £67,000. The capital of the colony is Stanley (pop. 700), originally founded as a port of refuge, on East Falkland. The group, first sighted by Davis in 1592, received its present name in 1689 from Captain Strong, in honour of his friend Lord Falkland. It was occupied by France in 1710 and 1764, when it was purchased for £30,000 by Spain, who immediately thereafter was compelled to surrender her claim on receiving the ultimatum of the British government. It was for a while evacuated, but was definitely occupied by Great Britain in 1833, and utilised as a penal colony until 1832.

**Fall**, the name applied in theology to the change of state with respect to sin which befell Adam and Eve in Eden. The Scripture version of the fact, and the allegorical and other spiritualised explanations that have been offered by theologians, are already discussed under ADAM; here it only remains to point out the special use made of it in the orthodox Augustinian and Calvinistic scheme of theology. The Fall was due to an external temptation offered by the devil, and the inheritance of sin and a corrupted nature descended through the first sinners to all their natural descendants, to whom the guilt of the first sin was imputed in what is called *original sin*. This was possible, because Adam, as the covenant head or federal representative of the whole human race, necessarily involved all mankind—his descendants—in the consequences of his breach of the *covenant* which God made with him at his creation. Christ is 'the second man' and 'the new Adam' (Rom. v. and 1 Cor. xv.), and in the new covenant made with God the believer, through Christ's merits imputed to himself, is freed from the consequences of the Fall in so far as the after-life is concerned. See ADAM, EVIL, and SIN.

**Fallacy**, the incorrect performance of the process of reasoning so as to lead to error. The science of Logic reduces sound reasoning to certain rules, and when any of these rules is violated a logical fallacy is the result. The time-honoured division was into two classes, according as the error lay in the *form* of the reasoning or in the *matter*: the former were entitled *in dictione*, or those appearing in the expression; the material were entitled *extra dictionem*, implying that the fault could not be detected from the language, but must be sought in a consideration of the meaning

or subject-matter. Mill proposed to classify all fallacies under (1) Fallacies of Simple Inspection, or Fallacies *a priori*, which includes the whole of what may be termed Natural Prejudices; (2) Fallacies of Observation; (3) Fallacies of Generalisation, including Induction; (4) Fallacies of Ratiocination or Syllogism; and (5) Fallacies of Confusion, comprehending the *petitio principii*, the *ignoratio elenchi*, and ambiguous language generally. Other classifications have been more or less elaborately carried out. But, owing to the enormous variety and intricacy of inaccuate and confused modes of thought, it is difficult to draw up a scheme at once complete and rigorously scientific. See the articles LOGIC, INDUCTION, SYLLOGISM; for Bacon's *ciddla*, prejudices influencing the judgment, see BACON; and for the subject of fallacies generally, see the text-books of logic, as those of Whately, Mill, Jevons, and Fowler.

**Falling Bodies.** See GRAVITATION, KINEMATICS, ATTWOOD'S MACHINE.

**Falling Sickness.** See EPILEPSY.

**Falling Stars.** See METEORS.

**Fallmerayer**, JACOB PHILIPP, a German traveller and historian, was born 10th December 1790, at Tschötsch, near Brixen, in the Tyrol. At the university of Landshut he studied law, history, and philology, and in 1826 was appointed to its chair of History and Philology. In 1831-34 he accompanied the Russian general, Count Ostermann-Tolstoi, in a journey through Egypt, Palestine, Syria, Cyprus, Rhodes, Greece, Turkey, and Italy, and twice afterwards (in 1840 and 1847) he revisited the East. The events of 1848 recalled him to Bavaria, and for a short time he sat as a deputy in the Frankfort parliament. Fallmerayer spoke a great number of European and oriental tongues. He died at Munich on 26th April 1861. His principal works are *Geschichte des Kaiserthums Trapezunt* (1827), *Geschichte der Halbinsel Morca im Mittelalter* (2 vols. 1830-36), and *Fragmente aus dem Orient* (2 vols. 1845). His views on the Slavonic origin of the modern Greeks excited the liveliest controversy at the time of their publication (1835). His complete works, with a Life, were edited by Thomas (3 vols. Leip. 1861).

**Fallopian**, GABRIEL, Italian anatomist, born at or near Modena in 1523. He was professor of Anatomy in 1548 at Pisa, and in 1551 at Padua, where he died, 9th October 1562. He devoted special attention to the anatomy of bones, and wrote careful descriptions of the ethmoid and sphenoid bones, and of the internal ear. The canal which transmits the facial nerve after it leaves the nerve of hearing is still known as the aqueduct of Fallopian. In myology he corrected various errors into which Vesalius had fallen. He also studied the organs of generation in both sexes, and the Fallopian tube which connects each ovary with the uterus (see OVARIES, UTERUS) is named after him. He was superintendent of the Botanical Garden at Padua, and had a reputation as a botanist. A complete edition of his works in four folio volumes was published in 1600.

**Falloux**, FRÉDÉRIC ALFRED PIERRE, COMTE DE, a French author and statesman, was born at Angers, 7th May 1811. He first drew attention to himself by two works penetrated by an ardent love of the old Bourbon order of things—*L'Histoire de Louis XVI.* (1840) and *L'Histoire de Saint Pie V.* (1844). In 1846 he was chosen deputy for the department Maine-et-Loire. In religion he advocated the ideas of Montalembert, in politics those of Berryer, and united with his Legitimist sentiments a love of liberty and

education strangely incongruous with the historic character of his party. After the revolution of February 1848 he exhibited much energy as a member of the Constituent Assembly, was one of those who organised the resistance to the insurrection of the 15th May, and, as reporter on the national workshops, pronounced for their immediate dissolution. He was also one of the most ardent promoters of the expedition to Rome. On the election of Louis Napoleon to the presidency, Falloux was appointed Minister of Public Instruction, an office which he held for only ten months. After the *coup d'état* he retired from public life to a country-seat near Angers, where he occupied himself with agricultural pursuits, and where he died, 6th January 1883. He was a member of the French Academy. His writings include *Souvenirs de Charité* (1857), *Méditations et Prières* (1863), and *Le Convention du 15 Septembre* (1864).

**Fallow** (from the same root as *Ger. fahl* or *fallb*, expressing a pale dun, tawny colour). This word sometimes signifies waste, uncultivated land; but usually it is applied to land that is ploughed and otherwise cultivated for a season without being cropped. The most of the wheat raised by the Romans was sown after the land was fallowed; indeed, the usual rotation was fallow and wheat alternately. It was only fertile soils that could long support such an exhausting system; hence resulted the decreasing produce which the later Roman agricultural authors so often speak of and lament.

The fallowing of land was introduced into all the countries which fell under the dominion of the Romans. Britain during their sway soon exported large quantities of wheat, and for centuries after the Romans left no other mode of cultivating the land was followed. It may here be observed that, wherever the system of fallowing without giving manure to the crops is practised, it necessarily supposes that the soil is at least moderately fertile. This system is most successful on argillaceous soils, which are retentive of organic manure, and which cannot be cleaned by any other method. The destruction of weeds, such as couch-grass (*Tritium repens*) with its long jointed roots, is the first great object of fallowing. The exposure of the soil-substance to the weathering action of the air and the rest given to the land are minor objects. The loss from washing out of valuable soluble substances, more especially nitrogen, by rain, is a serious disadvantage of fallowing; and this, along with the possibility of the land becoming more and more foul with weeds during a wet summer, makes the benefits of the practice extremely doubtful, unless under exceptional circumstances.

It was long before fallowing was introduced to any extent in Scotland; but about the beginning of the 19th century it was largely practised. Owing, however, to the draining of the soil and the extension of the green-cropping system, it is now confined to the most retentive clay-soils, where it affords the only means of thoroughly cleaning the land. Sometimes as many as three or four ploughings are given in summer before the seed is sown in autumn. In old cultivated countries land is commonly so much reduced in its organic matter that fallows require to be dressed with farm-yard manure, rape-dust, or guano, to obtain satisfactory crops. Since the general introduction of green crops the term fallow has departed in some measure from its original meaning. These crops are sown on what was formerly the fallow-break, and are now often styled fallow-crops. The land, no doubt, receives in some measure a fallowing; it is freed from weeds, and allowed to rest from the growth of grain crops. Bastard-fallowing is a term which is used in Scotland when hay-stubble is ploughed up in the end of

summer, freed from weeds, and sown with wheat in autumn.

**Fallow Chat.** See WHEATEAR.

**Fallow-deer** (*Dama vulgaris*), a native of the Mediterranean districts of Europe, Asia, and Africa, whence it has been introduced into other countries, such as Britain, where it leads a vigorous semi-domesticated life in many parks. It is a very graceful animal, standing about 3 feet high at the shoulders, coming in stature between the Roe-deer (q.v.) and the Stag (q.v.). The usual summer colour is reddish-brown with white spots, while in winter the spots are fewer and the general shade grayer. The tail is black above, white below. There are, however, numerous colour varieties—e.g. white forms. The antlers, which are confined to the bucks, or males, are cylindrical at the base, give off two tines at some distance apart, and then form a shovel-like or palmate expansion. The

Fallow Deer (*Dama vulgaris*).

young male of the first year has no antlers, and the increasing annual development is marked for six years. Fawn, pricket, sorrel, soare, buck of the first lead, and buck complete are the names used to distinguish the various grades. The eyes and ears are large, and under the former there lie conspicuous sub-orbital cavities, which are wholly glandular, and not 'breathing places,' as Gilbert White and others have supposed. The breeding season is in October, and the doe bears in June. There is generally a single fawn, though occasionally two. The fallow-deer seem naturally timid and gentle, and become readily accustomed to man. The flesh is much esteemed.

As to the introduction of this southern species into north Europe, certain information is wanting. It seems to have been unknown in Germany till the 16th century. James VI. of Scotland introduced a hardy variety from Norway, when he brought home his queen, Anne of Denmark. Sir V. Brooke describes a second species (*D. mesopotamica*) from Persia. The extinct Irish Elk is believed to have been allied to the imported species. See DEER.

**Fall River**, a busy manufacturing city and port of entry of Bristol county, Massachusetts, at the mouth of the Taunton River, 49 miles S. of Boston by rail. The town is well built, the handsome city hall and many other buildings being constructed of a fine granite quarried in the vicinity. It has a capacious and deep harbour, and is connected with New York daily by a line of large steam-packets. Fall River is noted for its cotton-mills, of which it contains nearly fifty, with about 1,500,000 spindles. Other manufactures are nails and machinery, abundant water-power being supplied by a tributary of the Taunton, which falls 130 feet in its last half-mile. Pop. (1870) 28,766; (1880) 49,006; (1890) 74,398.

**Falmouth**, a parliamentary and municipal borough and seaport of Cornwall, on the southern side of the estuary of the Fal, 18 miles NNE. of the Lizard, and 66 by rail WSW. of Plymouth. It chiefly consists of a narrow street, a mile long, with suburban terraces and villas on the heights behind; and it has a branch-railway (1863), a polytechnic society (1833), and a town-hall (1866). The harbour, one of the best in England, is 5 miles long by 1 to 2 miles wide, and 12 to 18 fathoms deep. The entrance is defended on the west by Pendennis Castle (c. 1538-44), which crowns a rock 198 feet high, and which in 1646 surrendered to Fairfax after a five months' siege; on the east, by St Mawes Castle (1543). Pop. of the municipal borough (1831) 4953; (1881) 5973; of the parliamentary borough, which includes Penryn, and which since 1885 has returned only one member, 18,072. From 1688 to 1850 Falmouth was one of the principal packet-stations for foreign mails. There is a considerable pilchard-fishery off the neighbouring coasts. The chief exports are tin, copper, pilchards, and fuel. Here orange and lemon trees yield plenty of fruit on open garden-walls. Falmouth has arisen since 1613, Sir Walter Raleigh having drawn notice to its capabilities. Charles II. incorporated it in 1661; and at one time it was a stronghold of Quakerism. See *The River Fal and Falmouth*, by C. J. (Truro, 1876), and Caroline Fox's *Memoirs of Old Friends* (1882).

**False Bay.** See CAPE COLONY.

**False Pretences.** See FRAUD. For False Money, see COINING; for False Sweating, see PERJURY; and for False Weights, see WEIGHTS.

**False Point**, a cape and harbour of Bengal, 43 miles E. of Cuttack by canal. The harbour, which has a lighthouse, is safe and roomy, and is considered the best between Calcutta and Bombay; it is the entrepôt for the trade of Orissa, and a regular port of call for the British Indian Company's steamers.

**Falsetto**, a term in singing for the highest register of a man's voice, which joins the natural or chest voice, and which, by practice, may be so blended with the chest-voice as to make no perceivable break. See VOICE.

**Falstaff.** See OLDCASTLE, and FASTOLF.

**Falster**, a Danish island in the Baltic, south of Zealand, which measures 26 miles by 16 at its widest part, and has an area of 183 sq. m. It is flat, remarkably fruitful, and well cultivated. Its inhabitants (30,212 in 1881) employ themselves chiefly in agriculture and cattle-breeding.

**Falun**, or FAHLUN (called also *Gamla Kopparberget*—i.e. 'the old copper-mine'), a town of Sweden, 57 miles W. of Gelle by rail. It has for more than six centuries been famous for its copper-mines, though the quantity of ore now obtained is much smaller than formerly. In 1650 the yield was 3150 tons annually; this, however, declined in 1690 to 1900 tons; at present it is only about 400 tons. The excavations extend for miles underground. Destroyed by fire in 1761, Falun was rebuilt on a regular plan; but its wooden houses have a sombre appearance, being blackened by the fumes of the numerous smelting-furnaces. Pop. 7507.

**Faluns**, a term given by the agriculturists of Touraine to shelly sand and marl, which they use as manure, and applied by geologists to the deposits from which they are obtained.

**Fama** (Gr. *Phēmā*), the goddess of rumour, a personification which appears in the works of the earliest poets. Sophocles makes her the child of Hope; Virgil, the youngest daughter of Terra, and sister of Encecladus and Cæus.

**Fama Clamosa**, in the ecclesiastical law of Scotland, is a wide-spread and prevailing report imputing immoral conduct to a minister, probationer, or elder of the church. When such report exists, a presbytery may commence process against a minister without the instance of any particular accuser, but as acting for the vindication of their own order, and in behalf of the morals of the community. If satisfied that the *fama* is not groundless, the presbytery serves the offender with a libel when no private party comes forward to execute it.

**Famagosta**, or FAMAGUSTA, a seaport on the east coast of Cyprus, on the supposed site of ancient Aisinoe. It was a place of importance during the Crusades; and under the Venetians from 1487 to 1571 it became a rich and flourishing seaport, with 30,000 inhabitants. On falling into the hands of the Turks after a long siege (1571), it began to decay; an earthquake in 1735 completed its ruin. The church of St Nicholas, now used as a mosque, contains many monuments of its former use, and is a fine specimen of medieval architecture; in it Richard I. of England crowned Guy de Lusignan king of Cyprus in 1191. Famagosta, which now has only about 660 inhabitants, possesses a natural harbour,  $1\frac{1}{2}$  mile long by  $\frac{1}{2}$  mile wide, but it is now almost sanded up. The chief exports are corn and its famous pomegranates.

**Familiar** (Lat. 'servant'), a supernatural being in attendance upon a magician, wizard, or other professor of the black art. The belief in spirits as especial patrons or guardians of individuals is very ancient, and is still widely spread among more than savage races. The guardian angel is indeed an integral part of his faith to many a Christian, as much as the *torngak* to the Eskimo, or the *genius natalis* to the ancient Roman. The genial and sportive guardian spirit of the household is also a venerable belief, and we find in Leviticus (xix. 31) a warning against familiar demons who give occult knowledge. During the middle ages the belief in 'enchanted rings' containing familiar spirits was widely diffused throughout Europe, the magicians of Salamanca and Toledo being especially famous for their skill in thus subjugating and imprisoning demons. The notion of familiar spirits is one perfectly natural to the Persians and Hindus, and Aladdin's 'slave of the lamp' is an example in point. A favourite form assumed by the familiar spirit in western Europe was that of a black dog. Such was the case with the famous Cornelius Agrippa, who was always accompanied by a devil in the shape of a black dog. When he saw that his death was at hand, according to Paulus Jovius, he took from the dog's neck a collar inscribed with magic symbols, and let him go with the words: *Abi, perdita Bestia quæ me totum perdidisti*. Butler, in his *Hudibras*, gives the dog the respectable office of tutor to the sage, and Wierus, the pupil of Agrippa, assures us that the animal was no cacodæmon but a natural pet. At least there is no doubt about the black dog in Goethe's *Faust* and his association with Mephistopheles, and there is good tradition that Simon Magnus also had a familiar in the same form. See DEMONOLOGY and WITCHCRAFT.

**Familiars.** See INQUISITION.

**Familistère.** See GUISE.

**Family**, from Latin *familia*, which meant, primarily, the holding in slaves, and secondarily, the whole domestic property, of a paterfamilias; but which, as commonly used, denoted the body of people within a gens (a number of such bodies making up the gens) who traced their descent through males to a common ancestor. The family, in civilised countries, is the little group consisting

of a man (its recognised head), his wife, and their children, which forms the inmost circle of relationship; and is connected more or less with other similar groups by relationship—relationship being reckoned by degrees, and counted through both father and mother, and determining rights of inheritance *ab intestato* and the law of incest. It was the universally received opinion until lately that this group existed substantially in the form known to us, with the father (sometimes with more than one wife) at its head, from the beginning of society; and that it was the germ from which all societies had been developed. It was thought there could be nothing more according to nature, and that there could have been nothing more primitive. Given such a family (so the reasoning went on), as the children and their descendants married, a number of similar groups would be formed round it, separate from one another, but all subject to their patriarch, in whose family they would be as long as he lived. They would probably separate from each other at his death, and expand and multiply each by itself; but by-and-by the family groups thus arising would find it convenient to go on living together, and thereafter they would become a set of separate tribes, many of which would be neighbours, and which might form in time the population of a district. Then the remembrance of their origin remaining, it would be easy for them to act together for common purposes; and this point arrived at, the descendants of one man would be well in train for constituting a people or nation. The history of Israel was thought to favour this account of the growth of tribes and states out of the family (known as the Patriarchal Theory); for it made each of the twelve tribes consist of descendants of a son or grandson of the patriarch Jacob, while the union of the tribes constituted the nation. In Genesis, too, the population of the world is represented as composed of tribes and nations descended from Noah's three sons, Shem, Ham, and Japhet. A modified form of this theory, put forward by Sir H. S. Maine, in his work on *Ancient Law* (1861), is still perhaps (at anyrate, wherever English is spoken) the most popular account of the origin of societies.

Maine assumed that the family of ancient Rome gives the true suggestion of what the primitive family was; and this he accordingly described as having consisted of a *paterfamilias*, who had *patria potestas*—i.e. unlimited power over his household, with his wife, his children, persons adopted by him, and slaves. The primitive relationship was in his view merely the bond made by common subjection to the *paterfamilias*; and as he assumed that women when they married would become subject to a new *paterfamilias*—that there would be no marriages between persons of the same family—he deduced that a woman's descendants would be out of the relationship of the family of her birth at first, and that thus relationship would afterwards come (he did not show how) to be traced through males only—the relationship called at Rome agnation—and that the clans, tribes, and societies into which the family gradually developed would everywhere be agnatic. But it is certain that early societies have not been all agnatic; and, indeed, the Roman type of family, with *patria potestas* and agnation, seems not to occur in any system of old law except the Roman. Maine's primitive family, too, is too complex to belong to the beginning of society; and, the social tendency of men considered, his primitive father who acknowledged obligations to nobody is hardly to be reconciled with human nature. His theory thus appears to be liable to objections special to itself. There are others which apply to the patriarchal theory in both forms; and two of these should be mentioned.

First, there are numerous societies (not indeed of the most important) and various forms of the family of which the patriarchal theory does not even attempt to give any account. And next, in the societies upon contemplation of which it was founded, a most serious difficulty for it is presented by the tribes, which consist of several clans, each clan considered separate in blood from all the others. The patriarchal theory of course involves that the clans in a tribe are all of the same blood. Maine suggested that the clans in those cases united by the help of some fiction analogous to adoption; but the suggestion is too vague to be useful.

One form of the family which the above-described theories neglected, but which has prevailed very largely, is especially interesting because of the disclosure of it which is given us in the Book of Genesis. In *beulah* marriage (the name is taken from Ceylon) the man goes to live with his wife's family, usually paying for his footing in it by service; he is in general an unimportant person in the family; and the children are not his—they belong to the family and kindred of his wife. He is lost to his family and kindred so long as he remains a *beulah* husband; he may even have (as in New Zealand) to fight against his own relations. *Beulah* marriage, as we know it, is commonly practised concurrently with marriage by purchase, in which the husband takes away the wife and becomes entitled to her issue; but a few tribes are known which make no other marriages. Now Jacob made a *beulah* marriage into the family of Laban; and Genesis, xxiv. 1-8, shows that there was much more than a possibility that Isaac, as a condition of marrying into his father's kindred, might have had to do the same. It need scarcely be pointed out that Samson's marriage with a Canaanite woman was a marriage of this type. Moreover, the first reference to marriage in the Scriptures (Genesis, ii. 24) is scarcely intelligible except as a reference to *beulah* marriage; it cannot possibly refer to a marriage of the Roman type, and scarcely to any marriage under which the bride would go to live with her husband's kinsfolk. In Jacob's case, Laban claimed the children. Jacob, his wives concurring, had stolen away with them—and it is clear that they were not his. Isaac had married into the same family, and his children were his, because he had been allowed to purchase the mother; but Jacob had not purchased—he had merely won for himself a place in Laban's family as the husband of Laban's daughters, and to that family both he (while he chose to remain in it) and his children thus belonged. The marriage of Isaac shows that *beulah* marriage was not exclusively practised by the kindred of Laban—that, when they saw fit, they gave their daughters to be taken away. But, in connection with this, it is to be noticed that the bridal gifts (bride's price) for Rebekah were given not to her father, but to her mother and brother. Here the father was not the head of the family, but a secondary person in it; the mother was the head, and the daughter belonged to her and her kin.

Such might the family be among early Semites. And, of necessity, the kinship was not agnatic. There was admitted relationship between Laban and Jacob, his sister's son; and, from Judges, ix. 1-4, and many other passages, it is to be gathered that anciently a man's relatives on the mother's side considered him 'their bone and their flesh'—i.e. of their clan, or, at anyrate, of their near kindred. Among the Semites of Arabia, *beulah* marriage was maintained for women of condition down to a comparatively late period; and at all times it was common for men who had been received into protection by a tribe to get a wife from it and to become incorporated with it through marriage.

Marriage by purchase ultimately supplanted the becnah marriage among the Hebrews, and became the prevailing marriage among the Arabs (and no doubt the same has happened in many cases). We proceed to describe the incidents which are found with it everywhere, while it is still in a direct or crude way a means of constituting family relations.

We find at this stage that the man often gets with his wife any children she has had already, and thus he gets children born of her while he has been her becnah husband; he gets, *a fortiori*, the child of which his wife is pregnant at the time of the marriage; he gets all children born to her thereafter whether they are his own or not (about which he is often found to be indifferent); and, in cases far from rare, he may even have children of the woman born after his death accounted his, and entitled to be his heirs, by means of what is called the *Levirate*. He may actually be the father of his wife's children, or of most of them; but very commonly he is ready to give her in loan, sometimes out of hospitality, sometimes for a price (in which latter case, the child, if any, may go to the borrower); he calls in the services of a friend who gives promise of being able to beget goodly offspring; and a child by his brother may appear to him to be in precisely the same case as a child by himself—in which we find an explanation of the *Levirate*. The foundation of the paternal relation in such a family is, in short, purchase, not paternity; the man has bought the woman and her issue, and (whether there be much paternal feeling or little) her children are counted his, as the increase of his cattle is. Purchase is here a means for taking children out of one kindred into another. Men desire children for the strengthening of their kindred, and no doubt because they have felt stirrings of paternal feeling. But paternity has not learned to be exacting, and it is of no avail to give any right to children. The purchase marriage of the early Arabs illustrates every point that has been mentioned, and so also does the family of the early Hindus.

The family founded upon purchase in this crude way is plainly a transitional form, and its future course is certainly upward. It takes a more familiar look, as paternal feeling strengthens, and the relationship of its members puts the contractual source of that relationship into the shade. And by-and-by purchase itself disappears or remains only in a symbol. In what may be taken to be an early stage, we very frequently find that at a man's death his brother succeeds him, inheriting his wife and children with his other property. Ultimately the sons succeed. And then we often find that (as in the Hindu family) the idea of family property is firmly established; so that the father, though having sole control, is regarded as only joint-owner with his sons of the family possessions—a state of things which must have originated in some form of joint-family, in which the father had been co-owner with his brothers or other kinsmen.

Now, to go back, with what does becnah marriage appear to be connected? We have seen its relation to marriage by purchase.

With becnah marriage, children belong to the family and kindred of their mother, and we find the same thing, and a reason for it, in the rudest family system which is known to us. This is what has been called the *Nair family*, because of the striking example of it found among the Nairs of Malabar. Among the Nairs bodies of the nearest relations form a joint-family, and hold their land in common, the control of the joint-interests being in the oldest male; but the family proper among them consists, when at the fullest, of a woman with her mother and brothers, and of her children. The uncles are the protectors of the children, who are their heirs; brother first succeeding to brother, and

then the sister's children succeeding. The woman has no husband living with her; there is no father in this family; the woman has a number of husbands who visit her in turn; and, as a result of this polyandry and of the composition of the family, no Nair knows or thinks of his own father, and it is the uncles who fulfil the father's part. The children are of the kin of the mother only, because there is uncertainty of fatherhood, and no man in the father's place. And we may safely take it that in nothing less than this, or something fully equivalent, can the ignoring of the father and tracing of kinship through the mother only have anywhere originated.

A number of rude tribes are known which seem to have only the Nair family; but the Nair polyandry is more commonly found alongside of a system of polyandry which yields a family of a more advanced sort, in which the wife goes to live with her husbands, and the husbands are brothers (which, in the Nair system, they need not be, and generally are not). The eldest brother takes the wife and is head of the family, all the children being accounted his. This has been called Tibetan polyandry, because of its prevalence in Tibet; and it has been shown upon direct evidence to have prevailed very widely, both in ancient times and in modern. The Arabian polyandry described by Strabo is of this kind; so also and more distinctly the Hindu polyandry disclosed in the *Mahābhārata*; the polyandry of the Britons, described by *Cæsar*, is closely akin to it, but somewhat different. In families of the Tibetan type, the brother-husbands have got the woman into their mastery (be it by capture or by exchange or purchase); the children may be seen, as with monandry, to be of the blood of their kindred; and they might have been peacefully added to that kindred wherever exchange or purchase had been thought of. Only a sufficiency of women and of the means of living would then be wanting to change (let us say, among the Arabs) the Tibetan family into the monandrous purchase family already described. And the Nair would similarly be changed into the becnah family. It is male kinship that is now found with Tibetan polyandry, the brothers in order succeeding to the headship of the family, and then the eldest son of the brotherhood.

And where this succession law appears in the monandrous purchase family, brothers first succeeding, and the sons only after them, we may reasonably infer that there has been a movement from the Tibetan to the monandrous family. The same conclusion may also be drawn wherever, with succession of son to father established (a more advanced stage), it is held that a man may beget a son for his brother either in his lifetime or after his death (the latter case being the *Levirate*—familiar as occurring among the Hindus and the Hebrews); that provided a man's wife is mother, it suffices that his brother should be father, as it would have done in the Tibetan family. A prevalence of the Nair family, again, at some earlier period may be inferred, as we have seen, from our finding kinship counted through females only, although the family where this occurs may not be Nair.

We find this kinship with monandry, usually with the man head of the house—another form of the family, husband and children not being counted relatives—very widely, and among peoples in very different stages of advancement. Thus, it is very common in tribes like those of Australia and America, and it is established also among peoples comparatively so far advanced as the *Ashantis*. In the greater number of Australian tribes, though polygamy is practised largely, and a wife is little better than a slave, and is valued chiefly for her services (licentious practices which tend to make

fatherhood uncertain being, however, exceedingly prevalent), children belong to the kindred of their mother, and, as the father is not allowed to marry women of his own kindred, not to that of their father; so that the children may be of as many kindreds as the man has wives, but are never of his own kindred. Among the Ashantis, amid distinctions of rank, with wealth accumulated and with women jealously watched over, we find children similarly counted of the kin not of their father, but of their mother, the sister's son being a man's heir in preference to his son; while among the Fantis, a neighbour people of the same race, failing a sister's son, the chief slave is heir, the son being excluded from succession in his father's family altogether. The family religions seem to have in this and similar cases preserved a kinship which is not now consistent with the domestic relations.

The same kinship has of course prevailed wherever the wife has been the head of the family, of which many examples, more or less trustworthy, have been collected. In some of these daughters only have been heirs (Lycia, Egypt), sons going into other families with or without a dowry. A former prevalence of this kinship (and therefore of the Nair family) may, moreover, be inferred from such facts as permission of marriage between persons closely related through the father (but not relations under female kinship)—e.g. brother and sister german, who might marry in a certain case in Attica (for which we also have in Athenæus a clear tradition of the Nair family—of a time when no man knew who was his father), and more generally, it would seem, among the Hebrews (Abraham and Sarah, Annon and Tamar); as the feeling for the sister's son which Tacitus noted among the Germans—which was precisely that of the rudest female kinship tribes; and, *a fortiori*, from the succession of the sister's son, if only to the sovereignty, as among the Celts of Scotland, or of the mother's brother, as in the story of Melenger. By inference the evidence for the Nair family may thus be greatly enlarged, as we have seen that the evidence for the Tibetan family may also be.

Taken altogether, the evidence suggests strongly that these two systems occurred commonly together among a people, as becnah marriage and purchase marriage do—each having left its mark upon the same people's customs. The evidence shows also, if good for anything, that the Nair kinship was supplanted (traces of it long remaining) by the kinship which the purchase family brought in or established.

So much polyandry among early men would of course indicate that very generally their circumstances were like those of most polyandrous peoples now, in that the struggle for existence was severe, and they had learned to keep down the number of their women by infanticide to the lowest possible point. And geologists have shown us that their circumstances were generally far harder than those of any peoples now known to us. As men have had to reason out for themselves systems of kinship, it is now intelligible that at first and for long they should not get beyond the kinships which are most obvious, those which arise through the mother, and which sufficed to connect the children with her tribe (polyandry of the Tibetan type being indeed impossible until this kinship has made a good deal of progress); and that thus the early bands of men at first acknowledged only the Nair kinship.

The theory of the growth of societies which the various forms of the family taken together seem to point to can now be indicated, but here it can only be outlined very briefly.

Among tribes of the ruder sort, whether having female or male kinship, the true family (and so

travellers constantly name it) consists of all those who are considered relatives—of all who are of the same Totem (q.v.)—all of them being prohibited from marrying each other (exogamy); being bound together by the regard they have for the totem; and also all liable equally to be struck at for each other's offences, and all bound equally to revenge each other's injuries (the blood-fend). The totem is usually an animal or plant after which they are named, and from which they believe themselves to be descended. The tribe among such peoples is not a body of kindred; it is made up of people of several different totems; and the same totems are usually spread over many neighbouring tribes—all those who are of the same totem in all the tribes constituting the totem family. Now exogamy and female kinship account for this interfusion of the totem families throughout the tribes. It is exactly what would arise if a number of neighbouring totem families, having the female or Nair kinship, became exogamous—i.e. ceased to take to wife their own women and took the women of their neighbours. And, as the whole system depends upon the totem, we must take it that the totem families existed separately before exogamy interused them. This gives us, for a beginning, a totem group or family having Nair kinship and not exogamous; and, next, when exogamy (in whatever way) became established, an admixture of neighbouring totems in each of the groups; which admixture, if male kinship supervened, would necessarily remain—except in so far as the scattered portions of the totem families joined together and drew apart and became each family a separate clan. With male kinship (i.e. children of the totem or kindred of their father) exogamy would bring no totem from the outside into a group; and, therefore, we are forced to believe that wherever a tribe consists of several exogamous male kinship clans or families, these must at first have had the Nair kinship. Exogamy has been the prevailing marriage law among all races; female kinship, too, is known upon direct evidence to have prevailed widely; and, accordingly, this gives a good explanation of the constitution of all the tribes which have consisted of several clans, that difficulty for the patriarchal theory for which Maine proposed the hypothesis of a fiction.

As to the family proper, we have, on this view, to believe that (though the partnership of brothers in women may have commenced in the totem group while still separate, when women would probably be got by capture), the kinship was Nair, or predominantly Nair, until the interfusion of the totems had taken place. After that, peaceful marriages could be made within the tribe between persons of different totems; they might be either of the Nair type or the Tibetan—these giving way, as circumstances improved, to becnah marriage and the more familiar form of monandry; and by-and-by, when men came to desire it, marriage agreements (made upon the consideration of exchange or purchase) would allow of children being added to the totem of their father. This brings us to the competition of the Nair or becnah family and the purchase family, which naturally ended in the triumph of the latter, followed by a progress therefrom to the family in its more familiar forms. But a kinship established in the totem family could not be easily supplanted; so that female kinship might have a long career under favourable circumstances. Licentious practices which make fatherhood uncertain, and servility to custom, seem to have maintained it among the lower tribes; while the force of religion—the totem (animal or plant or other natural object) having become a god, and its worship regulating in many ways the lives of its devotees—accounts for its having lasted among the higher African peoples.

Interfusion of 'families' (i.e. 'kindreds'), such as is produced by exogamy and female kinship, is nowhere more strikingly illustrated than among the Ashantis and their neighbour peoples.

For facts and reasonings bearing upon the subject of this article, see Sir H. S. Maine's works, especially *Ancient Law*, and *Early Law and Custom*; J. D. Mayne's *Hindu Law and Usage*; Bachofen's *Das Mutterrecht*, and in connection therewith, Giraud-Teulon's *La Mère chez certains Peuples de l'Antiquité*; *Studies in Ancient History*, and the *Patriarchal Theory*, by J. F. M'Lennan; also, 'The Worship of Animals and Plants,' *Fortnightly Review* (1869-70); *Kinship and Marriage in Early Arabia*, by W. Robertson Smith; Herbert Spencer's *Principles of Sociology*, vol. i.; Sir J. Lubbock's *Origin of Civilisation*; and Lewis H. Morgan's *Ancient Society*.

**Family**, in zoological classification, means an alliance of nearly related genera. Individual, species, genus, family, order, class, and phylum are the common categories of classification in ascending order, with intermediate ranks, such as sub-genus, sub-order, sub-family, section, and sub-phylum. Thus, the dolphin family—Delphinidae—includes the genera *Delphinus* or *Dolphin*, *Monodon* or *Narwhal*, *Delphinapterus* or *Beluga*, *Phocæna* or *Porpoise*, *Orca* or *Grampus*, &c., and is itself included in the order Cetacea, in the class Mammalia, in the phylum Vertebrata. See GENUS, SPECIES, TAXONOMY, ZOOLOGY.

**Family Compact**, the name given to certain political leagues entered into by the Bourbon kings of Europe. Of these, two deserve mention. The first, an agreement concluded between the kings of France and Spain in 1733, was aimed on the one hand against the ascendancy of Austria in Italy and on the other against the mercantile supremacy of Britain on the sea. Out of this arose a war between Britain and Spain in 1739. The second compact, signed in 1761, had for its object the union, in a close offensive and defensive alliance, of the Bourbon sovereigns of France, Spain, and the two Italian kingdoms Naples and Sicily, and Parma and Piacenza; and next year Britain declared war.

**Family of Love**, or **FAMILISTS**, or **DAVIDISTS**, a sect which appeared in Holland in the middle of the 16th century. It was founded by David Joris or George (1501-56), an Anabaptist of Delft, who left the Anabaptists about 1538, and founded the new communion, while apparently conforming to the Reformed Church (see ANABAPTISTS). In the reign of Edward VI., according to Fuller, Henry Nicholas, a disciple of Joris, came over to England, and commenced the perversion of silly people in a secret way. By 1572 they had apparently increased in numbers considerably, for in that year one John Rogers published a work against the *Horrible Secte of Grosse and Wicked Heretiques naming themselves the Family of Love*. In 1580 Queen Elizabeth issued a proclamation for the hunting out and punishing of this 'damnable sect.' The Family of Love, 'or Lust rather,' as old Fuller has it, tried in vain to insinuate themselves into the good graces of King James, and the society gradually disappeared in the 17th century. They disregarded dogma and church ceremonies, and insisted that religion consisted simply in love, which makes us one with God—a doctrine that led to extreme Antinomianism (q.v.).

**Famines**, or times during which there is a scarcity, more or less severe, more or less local, of food-supplies, are due to a variety of causes. They have been perhaps oftenest caused by drought or deficiency of rainfall, especially in tropical regions; by excess of rainfall, giving origin to floods and inundations, more particularly in northern climes; by excessive frosts and other irregular incidences of climatic conditions; by the ravages of insects (flies,

locusts, ants, grass-hoppers, &c.) and vermin (rats, mice, &c.); by the devastations of war; and by the wholesale destruction of forests, especially on hillsides, giving rise to drought—a cause which has operated more particularly in northern China. Apart from these causes, the occurrence of famine in a particular locality depends upon the ratio between the population and the food-supply for the time being of that district, or, more correctly, between the amount and extent of the failure in the supplies and the density of the local population. Amongst the factors which exert an injurious effect upon the food-supply must be mentioned not only backward and inadequate methods of agriculture, but sometimes also the system of agriculture in vogue; deficient means of communication and transport; misappropriation of the soil—i.e. using it for growing crops which add nothing to the food-supply when the land that is devoted to the production of the necessities of life is inadequate for the normal wants of the population; legislative interference, either preventing the free exploitation and development of the complete resources of the soil, or throwing obstacles in the way of the natural distribution of food-supplies; the ill-regulated distribution of food-supplies apart from governmental interference; sudden immigrations of large bodies of people into districts of confined area; the social customs and agricultural habits of a people making them principally dependent upon one kind of food, as the Irish upon the potato; the religious belief of a people restricting them to certain prescribed kinds of food; lack of foresight and energy in the administrative authorities, provincial, national, or general, as the case may be, together with the limited extent and inaccessibility of the resources they have at their command; insufficient resources and powers of organisation of private merchants; undue facilities for commercial speculation in grain and other necessities of subsistence; and the misapplication of grain, &c.—i.e. the using of it in undue quantity for brewing or distilling, and the like. Attempts have also been made to trace some law of relation between the occurrence of famines, more particularly in India, and the sun-spot cycle, the links of connection being the meteorological effects that are supposed to manifest themselves on our planet in dependence upon the cyclical phases of the waxing and waning of the sun's spots.

Famines cannot be wholly prevented. The powerful climatic causes to which they are principally due cannot be controlled by human agency, except to an extremely small degree, chiefly by the maintenance of river-banks and sea-banks, and by the regulation of the forests. The local conditions are in every case so diverse, and often so complicated, that it is fruitless to attempt to give more than a few general rules. In cases where the country is dependent upon irrigation for its fertility, it should be the first care of the inhabitants, or, failing them, of the government, to make provision for the storing of water, to regulate its distribution, and to utilise it in the most economical ways. But the most efficient methods of rendering governmental assistance are to improve the means of transport, to encourage more scientific systems of agriculture, to give warning to districts that are likely to be affected of the threatened approach of a period of scarcity, and then to leave the rest to the enterprise of private merchants. There should be no legislative restrictions on the free transmission of food-supplies from centres of abundance to districts which are suffering from famine. The systems of agriculture best calculated to prevent the occurrence of famines and counteract their devastating effects are perhaps those in which the

quantity of land in each farm is large enough to allow of a sufficient variety of crops being produced year by year, so that the cultivator need not necessarily be dependent upon the success of one single crop for his sustenance, or even his livelihood.

The appended list includes a few of the more important famines of the world, either from their historical significance or from the great destruction of life that attended them. A much more detailed list, together with a couple of excellent papers on the subject, by C. Walford, will be found in the *Journal of the Statistical Society* (1878-79).

| 879 A.D. | Universal famine.                | 1681.    | India, Asia generally.                            |
| 1003.    | England.                         | 1711.    | Carniola; lasted several years.                   |
| 1013.    | Famine throughout Europe.        | 1709-70. | India; three million people perished.             |
| 1022.    | In many parts of the world.      | 1781-83. | In Carnatic and Madras.                           |
| 1051.    | Mexico.                          | 1782-84. | In North-west Provinces, India.                   |
| 1052-00. | In Ghor, India.                  | 1790-91. | India.                                            |
| 1064-72. | Seven years' famine in Egypt.    | 1822.    | Ireland.                                          |
| 1069.    | In north of England.             | 1846-47. | Ireland; potato famine.                           |
| 1162.    | Universal famine.                | 1866.    | Bengal; one million and a half died.              |
| 1314.    | Silesia, Poland, and Lithuania.  | 1877.    | India.                                            |
| 1344-45. | India, especially in the Deccan. | 1877-78. | North China; nine millions reported to have died. |
| 1347.    | Italy.                           | 1888-90. | North China.                                      |
| 1401.    | Ireland.                         |          |                                                   |
| 1550-89. | Ireland.                         |          |                                                   |
| 1600.    | Russia.                          |          |                                                   |

It was after a famine of 1586 that the poor-law in England had its beginning. That of 1781-83 in India led to the institution for the relief of the native poor called *Monegar Choultry*. See also Reports of *Indian Famine Commission*, and Digby, *Famine Campaign in Southern India* (Lond. 1878).

**Fan**, an implement for creating a current of air, generally with the view of cooling the person. The term comes from the Latin *vannus*, the broad, shallow basket into which corn and chaff from thrashing were received to be tossed in the air so that the wind might carry away the chaff. The ordinary fan may consist of any light, flat, expanded surface set in rapid reciprocating motion by the hand; but for many mechanical operations, such as sifting, winnowing, ventilating, and extracting gases, rotating fan-blades are mounted, under such names as Fans, Fanners (q.v.), or Fan-blasts, by which strong and continuous air-currents are raised. The *Punkah* (q.v.) employed in India for circulating air in apartments is simply an enormous fan.

The common hand-fan, used as a personal accessory, is an implement of great antiquity, which naturally was prized most in regions where the heat was greatest. It is known to have been in use among the ancient Assyrians and Egyptians, and from its frequent representation on early Greek vases it must have been a familiar implement among that people. Those ancient fans were sometimes made of very large size, and carried on long shafts or poles by female slaves (*flabelliferæ*), eunuchs, or boys, whose duty was to keep the air in circulation, and to drive away flies from the table or the person. The *flabellum*, or fan to brush away flies from the sacred vessels, was used in the Western Church from the 4th till the 14th century; and gorgeous *flabella* of peacocks' feathers are still borne by the pope's attendants in solemn processions. Similar fans, used to keep flies from settling on the unbroidered case of the *torak*, may be seen in Holman Hunt's picture of 'The Finding of Christ in the Temple,' and Mr Butler's *Ancient Coptic Church* contains several pages on the use of the fan in that communion. Among eastern nations generally the fan was an implement of great importance, and large fans—like sunshades, to which they are closely allied—possessed special significance as symbols of authority and emblems of royalty. In Japan, where to this day the fan is an indis-

pensable adjunct of the daily life of all classes, large rich fans are used in ceremonial dances, in which they are accessories of peculiar significance.

Fans are of two kinds, the folding and the non-folding. To the latter class belong all state and ceremonial fans, while those carried about by ladies belong to the folding class. Beyond those distinctions, however, it is impossible to define the material, form, or structure of fans, these, especially in the case of non-folding fans, being endlessly diverse. The folding fan consists of two principal portions, the mount or leaf (*fr. feuille*) and the stick (*bois*). The leaf, which forms a segment of a circle, consists of two equal pieces of paper, fine parchment, satin, crape, tulle, or cotton, folded into from twelve to twenty-four equal folds. The stick consists of a number of 'brins' equal to the folds in the leaf, with two stout outer guards (*panaches*). These may consist of wood, ivory, mother-of-pearl, or metal, richly carved, inlaid, or otherwise worked in the case of fine fans, the leaf of which may be elaborately painted. The upper part of the brins is continued by thin, flat strips of wood between the folds of the leaf. The brins with the outer guards are collected and held together at the head or end (*tête*) by a pin passing through them, which forms the pivot on which the fan opens or closes. The folding fan is said to have been a Japanese invention which originated in the 7th century, the idea having been supplied by the wing of the bat. From Japan the invention passed into China; but it was not till about the beginning of the 16th century that such fans began to be used in Europe. They first found their homes in Italy and Spain, but early in the 16th century they came into use in France, and their manufacture was established in Paris, where since that time they have formed the most prominent of the small industries known as *articles de Paris*. In 1673 the *maîtres éventailistes* were formed into a corporation by Louis XIV. French fans of the 18th century became real works of art, on which frequently the ability and taste of the most skilful goldsmiths, jewellers, metal-workers, and carvers were combined with the decorative painting of artists of the foremost position. Fans painted by the 18th-century artists Watteau, Lancret, Pater, Boucher, &c. command very high prices; and such eminent artists of the 19th century as Diaz, Lamé, Glaize, Isabey, Jacquemart, &c. have devoted their talents to fan-painting. See O. Uzanne, *The Fan* (Eng. trans. 1883), and *English Fans and Fan Leaves*, by Lady Charlotte Schreiber (1889).

**Fanariots**, the name given to the Greeks inhabiting the Fanar or Fanal quarter of Constantinople. They appear to have been originally descendants of such noble Byzantine families as escaped the fury of the Turks, and their numbers were afterwards recruited by emigrants from different parts of the old Byzantine empire. They have figured in Turkish history principally as diplomatists, administrators, and bankers. From 1669 onwards the dragomans of the Porte were usually chosen from amongst them. From them too were chosen, until the outbreak of the revolution in 1822, the hospodars of Wallachia and Moldavia, while, in addition, the disposal of most of the civil and military posts under the Turkish government was in their hands. In the Greek struggle for freedom (1821-26) the Fanariots displayed no great zeal or activity, but nevertheless were severely punished by the Turks.

**Fandango**, like the *Bolero*, is an old Spanish national dance, in 3 time. It is danced most gracefully in the south country, usually to the accompaniment of a guitar, while the dancers beat time with castanets. It proceeds gradually from a slow

and uniform to the liveliest motion; and, notwithstanding the simplicity of the *pas*, expresses vividly all the gradations of the passion of love. See DANCE.

**Faneuil**, PETER, a merchant in Boston, U.S., was born of a Huguenot family at New Rochelle, N.Y., in 1700, and died in 1743. His name is remembered from his having built the Faneuil Hall in Boston at his own cost (1742), and presented it to the town. Originally the building contained a hall for public meetings, with lesser apartments above, and a basement used as a market. In 1761 it was destroyed by fire, and rebuilt. During the revolutionary struggle with England the hall was so often used for important political meetings that it became known as 'the cradle of American liberty.' In 1805 the building was increased in height by an additional story, and also increased in width.

**Fanners**, a machine employed to winnow grain, driven by hand or by machinery. In passing through the machine the grain is rapidly agitated in a sieve, and as it falls through a strong current of wind, created by a rotatory fan, the chaff is blown out at one end, whilst the cleansed particles fall out at an orifice beneath. The fanners superseded the old and slow process of winnowing, which consisted in throwing up the grain by means of sieves or shovels, while a current of wind, blowing across the thrashing-floor, carried away the chaff. A machine for the winnowing of corn seems for the first time to have been made in Britain by Andrew Rodger, a farmer on the estate of Cavers in Roxburghshire, in the year 1737. Strangely enough, there was a strong opposition to the use of this helpful instrument, the objectors seeing in it an impious evasion of the Divine will. To create an artificial wind was a distinct flying in the face of the text Amos, iv. 13: 'He that formeth the mountains and createth the wind.' See BLOWING-MACHINES.

**Fanning**, a coral island in the Pacific, lying in 3° 51' N. lat. and 159° 22' W. long. It has about 150 inhabitants, and was formally annexed by Britain in 1888, as lying in the path of a possible submarine cable between Canada and Australia. Fanning Island is also called American Island. The name of Fanning Islands is sometimes given to the group comprising Fanning, Christmas, New York or Washington, Jarvis, and Palmyra Islands.

**Fano** (Lat. *Fanum Fortunæ*, so called from the temple of Fortune commemorating the defeat of Hasdrubal on the Metaurus), a town and seaport of Italy, on the Adriatic, 29 miles N.W. of Ancona by rail. Its cathedral of St Fortunato and numerous churches contain paintings by Domenichino, Guido, Guercino, &c.; and there is a triumphal arch of white marble, raised in honour of Augustus. The inhabitants (9484) carry on considerable trade in corn, oil, and silk goods; but the harbour is now greatly choked up with sand.

**Fan Palm**, a name common to all those palms which have fan-shaped (palmate) leaves, but more particularly applied to *Chamærops* (q.v.), and in the United States to the Palmetto. The Talipot Palm (*Corypha umbraculifera*) is also called the Great Fan Palm.

**Fans**, a race of aborigines, but apparently not true Negroes, in western equatorial Africa, between the Gaboon and the Ogoway rivers, first accurately described by Du Chaillu. They are a fine race of savages, but are avowedly cannibals, and their morals have suffered sadly from contact with the French. They are constantly moving westwards, and in 1867 Admiral Fleuriot de Langle estimated that no fewer than 60,000 had within a few years approached the French settlements on the Gaboon.

**Fanshawe**, SIR RICHARD, was born at Ware Park, Hertfordshire, in 1608, studied at Jesus College, Cambridge, and afterwards entered the Inner Temple, but found law distasteful, and went abroad to study languages. On the outbreak of the Civil War he took part with the king, and while with him at Oxford met and married in 1644 the lively and brave Anne Harrison (born 1625), with whom he lived in the most complete happiness throughout life. In 1648 he became treasurer to the navy under Prince Rupert, in 1651 was taken prisoner at the battle of Worcester, and on Cromwell's death withdrew to the Continent. After the Restoration he was appointed ambassador at the courts of Portugal and Spain, but was superseded by Lord Sandwich early in 1666, and before his return died suddenly at Madrid on the 26th June of the same year. His devoted wife carried his body to England for burial in Ware church, had much difficulty in recovering but a part of her husband's arrears of salary and money expended in the king's service, and survived till 1680. Fanshawe's works include *The Faithful Shepherd* (1647), a translation from the Italian of Guarini; *Selected Parts of Horace* (1652); and *The Lusiad, or Portugal's Historical Poem* (1655), a translation from Camoens. Lady Fanshawe's charming *Memoir* of her husband was first printed by Sir Harris Nicolas in 1829.

**Fantasia** is, like Capriccio, a title given to an instrumental composition whose form cannot be classified under any of the recognised species, but is a product of the individual fancy of the composer. In the music of the last two centuries it was applied to pieces containing imitative passages, similar to the vocal madrigal; and hence the 'working-out' section in the sonata form has obtained the name of 'free fantasia.' The modern fantasia is, however, usually a pot-pourri—a medley of favourite airs, with intermediate 'brilliant' passages—a species of effusion to which it is to be regretted an impetus has been given by pianists of the rank of Thalberg and Liszt.

**Fantis**, a Negro people on the Gold Coast, belonging to the same stem as their Ashanti (q.v.) neighbours, but possessing a greater muscular development. They were once the most powerful race in that part of Africa, but early in the 19th century were subjugated by the Ashantis, and since the Ashanti wars have come completely under British rule. In the war of 1873-74 they proved cowardly and worthless allies. Not very successful efforts have been made by Wesleyan and Swiss missionaries to convert the coast tribes to Christianity. See Brackenbury and Huyshé, *Fanti and Ashanti* (1873).

**Fantocini**. See PUPPET.

**Fan-tracery Vaulting**, a kind of Late Gothic vaulting (15th and 16th centuries), so called from its resemblance to a fan. The ribs or veins spring from one point, the cap of the vaulting shaft, and radiate with the same curvature, and at equal intervals, round the surface of an inverted curved cone or polygon, till they reach the semicircular or polygonal ribs which bound the upper part of the cone and divide the roof horizontally at the ridge level into diamond and other patterns. The spaces between the ribs are filled with foils and cusps, resembling the tracery of a Gothic window; hence the name *fan-tracery*. The spaces between the outlines of the fans at the ridge level are called by Professor Whewell (*German Churches*) ridge lozenges. In Henry VII.'s Chapel, Westminster, one of the best examples of this kind of vaulting, these lozenges are occupied by pendants, which produce a very astonishing effect, looking like arches resting on nothing. They are,

however, supported with great ingenuity by internal arches, rising high above the visible vaulting.

Fan-tracery :  
From the Cloisters, Gloucester Cathedral.

This arrangement is one of those *tours-de-force* which astonish the vulgar, but are only adopted when art has reached a low level and has in a great measure given place to artifice. Fan-tracery is a very beautiful kind of vaulting, and is peculiar to England, where it originated, and where alone it was practised. Among the finest examples are St George's Chapel, Windsor, and King's College Chapel, Cambridge. Fan-tracery is also frequently used in the vaulting of cloisters, as at Gloucester, Canterbury, and Chester.

**Farad** (from Faraday), the name of the practical unit of electrical capacity, first given by the British Association Committee on Electrical Standards in 1863, and authorised by the International Electrical Congress held in Paris in 1884. Under **ELECTRICITY** will be found the definitions of the ampère, the volt, and the ohm, which are respectively the practical units of current, potential, and resistance. The Coulomb is the name given to the unit of quantity, and is the quantity of electricity transferred by a current of one ampère in one second; and then the farad is defined as the capacity of a conductor which when raised to a potential of one volt has a charge of one coulomb. The farad is, however, an inconveniently large quantity, so that it is customary to measure capacities in *microfarads*, the microfarad being the millionth part of a farad. See also **MAGNETISM**.

**Faraday**, MICHAEL, one of the most distinguished chemists and natural philosophers of the 19th century, was born, a blacksmith's son, at Newington Butts, near London, 22d September 1791. At thirteen he was apprenticed to a bookbinder; yet even then he devoted his leisure hours to science, and made experiments with an electrical machine of his own construction. Chance having procured him admission, in 1812, to the chemical lectures of Sir H. Davy, the latter engaged him as his assistant at the Royal Institution. He travelled to the Continent with Davy, as his assistant and amanuensis. On their return to London Davy confided to Faraday the performance of certain experiments, which led in his hands to the condensation of gases into liquids by pressure. In 1827 he succeeded to Davy's chair of Chemistry in the Royal Institution. He was created D.C.L. in 1832.

In chemistry his treatise on *Chemical Manipulation* (1827; 2d ed. 1842) is even now a very valuable book of reference. As discoveries or investigations of a high order in this branch of science

we may mention new compounds of chlorine and carbon (1821); alloys of steel (1822); compounds of hydrogen and carbon (1825); action of sulphuric acid on naphthalene (1826); decomposition of hydrocarbons by expansion (1827); and the very valuable series of experiments, made in 1829-30, on the manufacture of glass for optical purposes, which resulted in one of his greatest discoveries, to be afterwards mentioned.

As practical applications of science his suggestions as to the preparation of the lungs for diving and the ventilation of lighthouse lamps are conspicuous, as are also his celebrated letter on table-turning and his lecture on mental education.

To enumerate only the most prominent of his publications on physical science, we may commence with the condensation of the gases (already referred to); then we have limits of vaporisation, optical deceptions, acoustical figures, re-gelation, relation of gold and other metals to light, and conservation of force. Of these the condensation of gases into liquids and solids, though in some cases previously effected by others (and Faraday was ever the foremost to acknowledge another's priority), he really made his own, not only by the extent and accuracy of his experiments, but by the exquisite experimental methods by which he obtained the results. His ideas on re-gelation and its connection with the motion of glaciers have not met with universal acceptance, though (see **HEAT**, **ICE**, **GLACIER**) there is no dispute as to his being correct in his *facts*. In regard to conservation of force, he seems to have been misled by the incorrect use of the word *force* (q.v.), for in his article on the subject he describes experiments made with the view of proving the conservation of force proper; whereas the doctrine of conservation asserts merely the conservation of 'energy,' which is *not* in any sense force. He *may* be right also; but, if so, it will be by a new discovery having no connection whatever with 'conservation of energy.'

His Christmas lectures at the Royal Institution, though professedly addressed to the young, contain much that may well be pondered by the old. His manner, his unvarying success in illustration, and his felicitous choice of expression, though the subjects were often of the most abstruse nature, were such as to charm and attract all classes of hearers. Besides his *Lectures on the Non-metallic Elements* and *Lectures on the Chemical History of a Candle*, we have his *Lectures on the Physical Forces*, a simple work, but in reality most profound, even in its slightest remarks.

But the great work of his life is the series of *Experimental Researches on Electricity*, published in the *Philosophical Transactions* during forty years and more. Fully to understand all the discoveries contained in that extraordinary set of papers would require a knowledge of all that has been discovered during that time as to electricity, magnetism, electro-magnetism, and diamagnetism. We may merely mention the following, almost all of which are discoveries of the *first* importance. They are given in the order of publication, which is nearly that of discovery: (1) Induced electricity (1831), comprehending and explaining a vast variety of phenomena, some of which have already been applied in practice (especially as magneto-electricity) to lighthouses, electro-plating, firing of mines, telegraphy, and medical purposes—electric currents derived from the earth's magnetism; (2) the electrotonic state of matter (1831); (3) identity of electricity from different sources (1833); (4) equivalents in electro-chemical decomposition (1834); (5) electrostatic induction—specific inductive capacity (1838); (6) relation of electric and magnetic forces (1838); (7) the electricity of the

Gymnotus (1839); (8) hydro-electricity (1843); (9) magnetic rotatory polarisation (1846), effected by means of the optical glass already mentioned; (10) diamagnetism and the magnetic condition of all matter (1846); (11) polarity of diamagnetics, and the relation of diamagnetism to crystalline forms (1849); (12) relation of gravity to electricity (1851)—this, as before remarked, is Faraday's attempt to prove a conservation of force proper; (13) atmospheric magnetism (1851), an attempt to explain the diurnal changes of the earth's magnetic force by the solar effect on the oxygen of the air, a very interesting paper. Faraday's work is not only of extreme importance in itself, but it has been of the utmost consequence to science by leading Clerk-Maxwell to his wonderful investigations of the dynamics of the electro-magnetic field and the electro-magnetic theory of light.

Faraday, who had received a pension in 1835, was in 1858 given a house in Hampton Court. In 1862 he delivered his last discourse on 'gas-furnaces,' and advocated the use of magneto-electric light in lighthouses. In 1865 he resigned the position of adviser to the Trinity House, also that of director of the laboratory of the Royal Institution. Faraday, who was a devout Christian and a member of the religious body called Sandemanians or Glassites, died at Hampton Court, 25th August 1867. See Life by Tyndall (1868; 4th ed. 1884), Bence Jones (1870), and J. H. Gladstone (1872).

#### Faradisation. See ELECTRICITY (MEDICAL).

**Farázī** (Arab. *farāiz*, 'divine ordinances'), a sect of reformed Mohammedans, numerous in Eastern Bengal since the middle of the 19th century. The sect originated in a puritan reaction against many obvious corruptions into which the Islamism of Bengal had fallen; but they differ from the orthodox Sunnites (of whom they may be regarded as a branch) in rejecting traditional custom, and in holding that the Koran is the sole and complete guide to spiritual life.

**Farce** (Ital. *farsa*, from Lat. *farcire*, 'to stuff'), a dramatic piece of a broad comic character. The difference between it and comedy proper is one of degree and not of kind. The aim of both is to excite mirth; but, while the latter does so by a comparatively faithful adherence to nature and truth, the former assumes to itself a much greater license, and does not scruple to make use of any extravagance or improbability that may serve its purpose. It does not therefore exhibit, in general, a refined wit or humour, but contents itself with grotesque rencontres and dialogues provocative of fun and jollity. The beginnings of Greek and Roman comedy consist of rustic farces or pantomimes (see *ATELLANÆ*); the first farces, in the modern sense, were composed by the fraternity of the Bazoche (q.v.) in Paris, as a contrast to the ecclesiastical plays performed by the religious orders. The most widely celebrated and most important of early farces is that of the advocate *Maître Pierre Patelin*, which was acted in the 15th century, and quickly spread itself over Italy and Germany. It is full of genuine comic quality, and its dialogue has brightness and reality. See L. E. Chevaldin, *La Farce de Patelin et ses Imitations* (Paris, 1889), from the work by Dr K. Schaumburg. Subsequently Molière elevated and refined the farce into his wonderful series of comedies of character. In England the origin of the modern farce dates from about the commencement of the 18th century. Of all the numerous farces which have been performed before English audiences only those of Samuel Foote, who reverted, however, to the abuse of personal mimicry which characterised the earliest farces, have kept a place in literature. See *DRAMA*.

**Farcy** in horses depends upon the same causes as Glanders (q.v.)—in fact, is an outward manifestation of glanders. The absorbent vessels of the superficial parts of the body, but usually those of one or both hind limbs, are inflamed, tender, swollen, hard, and knotted. The vitiated lymph thus poured out softens, and ulcers or farcy buds appear. Unlike the ulcers of glanders, they are sometimes thought to be curable, but an animal apparently cured is not safe to be with other horses, as the *contagium*—the *Bacillus mallei*—almost invariably remains, and the animal is thus a centre of infection and a source of danger.

Farcy and glanders are included in the contagious diseases dealt with by the Contagious Diseases (Animals) Acts, 1878-86. See handbook of said Acts, pp. 126, 563, and 631.

#### Fardel-bound. See CONSTIPATION.

**Fareham**, a market-town and watering-place of Hampshire, on a creek at the north-west end of Portsmouth harbour, 12 miles SE. of Southampton and 9 NW. of Portsmouth. It has earthenware manufactures and shipbuilding. Pop. (1851) 3451; (1881) 7183.

**Farel**, GUILLAUME, one of the most active promoters of the Reformation in Switzerland, was born in 1489 at Gap, in Dauphiné. He studied at Paris, and was at first distinguished by his extravagant zeal for the practices of the Catholic Church; but, moved to the study of the Scriptures, he was converted to Protestantism, and, being by nature vehement even to indiscretion, he immediately commenced to proselytise. The chief scene of his labours was France and Switzerland. At Basel, in 1524, he opened his career of controversy and evangelisation by publicly sustaining thirty theses on the points in dispute between Roman Catholicism and Protestantism. He subsequently preached at Strasburg, at Montbéliard, and at Neuchâtel. In 1532 he went to Geneva, but soon had to leave the city. He returned in 1533, was again compelled to withdraw, but once more entered it in 1534; and in 1535 the town-council of Geneva formally proclaimed the Reformation. Farel, however, was a missionary, not a legislator, and the organisation of the Genevan Church passed into the hands of Calvin (q.v.). The severity of the new ecclesiastical discipline produced a reaction, and in 1538 the two Reformers were expelled from the city. Farel took up his residence at Neuchâtel. In 1557, along with Beza, he was sent to the Protestant princes of Germany, to implore their aid for the Waldenses, and on his return sought a new sphere of evangelistic labour in the Jura Mountains. When trembling upon three-score-and-ten, he married a young wife. In 1560 he proceeded to his native Dauphiné, and passed several months preaching against Catholicism; and in November 1561 he was thrown into prison for a time. He died at Neuchâtel on the 13th September 1565. His works were mainly polemical. See the German work by Kirchhofer (Zur. 1833); two French works by E. Schmidt (1834 and 1860); and a Life in French by Goguel (1873).

**Farewell**, CAPE, the southern extremity of Greenland, lying in 59° 44' N. lat. and 43° 54' W. long., consists of a rocky hill, nearly 1000 feet high, situated on an island off the coast. It is generally beset with ice, which appears to come from the north-east and to sweep round into Davis Strait. Hence the cape is but little known; and, in fact, the Danish traders and seamen generally round it at more than 100 miles distance.

**Fargo**, capital of Cass county, North Dakota, on the Red River of the North, 254 miles W. of Duluth by rail. From an insignificant village in 1874 it has become the financial and commercial

centre of the state, with six banks, as many public schools, a Congregational college, and numerous churches. Flour is the chief manufacture. Pop. 10,000.

**Faria y Sousa**, MANUEL DE, a Portuguese historian and poet, was born near Pombal in 1590, studied at Braga, next was secretary to his kinsman the Bishop of Oporto, afterwards lived at Madrid and Lisbon, and became in 1631 secretary to the Spanish embassy at Rome, where he enjoyed the favour of Pope Urban VIII. Three years later he returned to Spain, and died at Madrid in 1649. His writings fill more than sixty volumes, partly in Spanish, and comprise works on Portuguese history, on Portugal and its possessions in America and Africa, and commentaries on Camoens. His Portuguese poems comprise about two hundred good sonnets and twelve eclogues, and it is mainly by these, and also by three theoretical treatises on poetry, that he has influenced the development of the poetic literature of Portugal, in which he was long regarded as an oracle. His poetry exhibits talent and spirit, but is on the whole tasteless and bombastic.—He must not be confounded with Manuel Severin de Faria (1583–1655), who was one of the most learned numismatists of his age.

• **Faribault**, capital of Rice county, Minnesota, on the Cannon River, 53 miles S. of St Paul by rail, with a Catholic academy and convent, a state institution for the deaf, dumb, and blind, and the Seabury divinity school. It has manufactures of flour, bricks, furniture, &c. Pop. (1885) 6439.

**Faridkot**, one of the Sikh cis-Sutlej states, south-east of Firozpur, with an area of 612 sq. m., and a pop. (1881) of 97,034. Under the political superintendence of the Punjab government, it is ruled by a rajah, resident in the town of Faridkot (pop. 6393), 60 miles SSE. of Lahore.

**Faridpur**, chief town of a district of the same name in the delta of the Ganges, 110 miles NE. of Calcutta. Pop. 10,263.—The district, forming a tongue of land between the great rivers Ganges and Madhumati, sinks in the south into a vast swamp, while during the rains boats of some size can ply over nearly the whole surface. Rice is, of course, the principal crop; sugar is grown and manufactured, and forms the staple of the district trade; and the river traffic and extensive fisheries employ large numbers of the inhabitants. Area, 2267 sq. m.; pop. 1,631,734.

**Farina**, a Latin term for meal or flour. It is also frequently extended to many substances which agree with the meal of the corn-plants or Cerealia in containing much starch; and food made of such substances is often called *farinaceous*. In South America the name is commonly applied to the meal of the cassava.

*Fossil farina*, mountain milk, or *Agaric mineral*, is a deposit of silicified animalcules, obtained from China, &c. In 100 parts it contains of silica 50½, alumina 26½, magnesia 9, water and organic matter 13, with traces of lime and oxide of iron.

**Farina**, JOHANN MARIA. See EAU DE COLOGNE.

**Farini**, LUIGI CARLO, an Italian statesman, was born in 1812 at Russi, in the province of Ravenna. He studied medicine at Bologna, and practised with success in his native city, but in 1841 had to leave the Papal States for Turin, owing to the part he had taken in politics. The amnesty and liberalism of the new pope, Pius IX., called him to Rome in 1846, where he became an under-secretary for Home Affairs, and held office under the ill-fated Rossi. Farini next found in Piedmont public honours as well as a home. In

1851 he became minister of Public Instruction, in 1859 provisional governor of Modena, in 1861 minister of Commerce in the last cabinet of Cavour, and he was himself premier from December 1862 till the breakdown of his health in the following March. He died near Genoa on 1st August 1866; and in 1878 his remains were translated to Russi. Among Farini's literary productions may be mentioned *Il Stato Romano*, translated into English by Mr Gladstone (4 vols. Lond. 1851–54), and *Storia d'Italia*, a continuation of Botta's celebrated work.

**Farm** (A.S. *feorm*; Low Lat. *firma*, from Lat. *firma*, 'durable'), the term usually employed to denote a piece of land, either pasture or arable, held in lease by a tenant from the proprietor; but of course the term farmer is often applied to a person who owns as well as cultivates land. In America the farmer usually owns the land he cultivates. In this work the history and present position of agriculture, agricultural statistics, and the division of land are dealt with under the head AGRICULTURE; and other matters relevant to farming (such as cattle, dairy, landlord and tenant, lease) are treated under the various heads cited at the end of that article.

**FARM BUILDINGS**.—The buildings of a well-appointed farm in Great Britain consist of a residence for the farmer and his family, cottages for the farm-labourers, and the farm-steading. The dwelling-house varies to some extent with the size and character of the holding, the 'rules of the estate,' the fashion of the district, and the taste and social standing of the tenant. Modern farm dwelling-houses upon holdings of about 200 acres and upwards are, as a rule, both commodious and comfortable, substantial in construction if not ornate in external appearance, usually surrounded by simply but tastefully laid out grounds, with a moderately sized garden—for, despite the old adage, farmers are not now all bad gardeners. The dwelling-house should be from 50 to 200 yards distant from the steading, and, if possible, upon a slightly higher level, and so situated that from the farmer's parlour and bedroom windows the whole of the steading and stack-yard may be in view.

The servants' cottages should be near the steading, perhaps at the opposite side from the farmer's dwelling-house. The cottages should be plain, substantial, and roomy; they are often in one continuous row, often in pairs, seldom built singly. Each family may have three or four compartments, with a separate door, and a separate plot of ground for garden produce. Cottages for farm-servants are now more fully provided than prior to 1870; and it is well known that, where there is ample cottage accommodation, the supply of agricultural labour is, as a rule, both abundant and of good quality.

The *farm-steading*, as the term is understood in its narrowest and most generally accepted sense, consists of erections provided for the accommodation of the crops, stock, and farm implements and machines. The cost, character, and capacity of the farm-steading vary not only with the extent of the holding, the system of farming pursued, and the situation of the farm in regard to climate, but also to no small extent with the tastes and desires of the land-owner, and perhaps likewise, although to a smaller extent, with the fancies of the tenant. It is the presumption that all the buildings and other permanent equipments of the farm are provided by and are the property of the owner of the soil. The character of the steading is therefore, as a rule, determined by the 'rules of the estate.' These estate rules too often enforce the observance of certain plans irrespective of the exceptional

necessities and peculiarities of individual farms. On this account, and through a widespread ambition on the part of both landlords and tenants for imposing and almost luxurious farm buildings—an ambition fostered by, if not born of, the times of exceptional prosperity experienced prior to 1875—an excessive and unreasonable amount of capital has in many cases been sunk in the buildings of the farm, thus placing upon the land a burden which it is ill able to bear, and which is therefore detrimental alike to the land-owner and to the tenant. The greatest amount of steading accommodation is required upon mixed husbandry farms, where a large quantity of home-grown produce is consumed by cattle in winter. Unfortunately upon such a farm the maximum expenditure is required where the land is, as a rule, least able to bear heavy burdens—viz. in the cold northern districts, where substantial and comfortable houses have to be provided for the stock during the long and severe winters. In many instances there is four or five times as much money sunk in buildings—i.e. apart from the dwelling-houses—upon mixed husbandry farms in the north of Scotland as upon similar farms in the south of England. For farms exceeding 200 acres in extent the outlay upon buildings would range from £4 to £10 per acre.

The following estimate of the cost of buildings for different farms is based upon actual experience of extensive estates in Scotland, rent instead of acreage being taken as indicating the character and wants of the farm—viz.: £80 annual rent—dwelling-house, £190; offices or steading, £310; total, £500. £160 annual rent—dwelling-house, £325; offices, £475; total, £800. £240 annual rent—dwelling-house, £410; offices, £740; total, £1150. £500 annual rent—dwelling-house, £500; offices, £1100; total, £1600.

The farm-steading is usually situated as near as possible to the centre of the holding, on a dry, airy, yet well-sheltered elevation, with the water-supply abundant, if such is to be had on the farm, but not in close proximity to stagnant water or swampy ground. The open part of the steading should, as a rule, have a southern exposure, yet the immediate situation as to shelter may warrant variations from this rule. The most common and convenient plan for a farm-steading is in the form of three sides of a square or parallelogram, with a wing down the centre, and perhaps also stretching out a short distance at the back of the cross wing, the dimensions of the square or parallelogram being so regulated as to provide the required capacity in the various compartments. Modern experience has fully demonstrated the advantages of covered courts for cattle. In most improved steadings, therefore, the whole or greater part of the spaces between the centre and side wings is roofed and arranged as courts for cattle. The whole of the season's dung is often accommodated in these courts, and is benefited by the treading of the cattle, while the roof saves it from damage by washing with rain-water. Where good management prevails, the liquid manure is collected in a tank close to these courts, and periodically pumped over the heap of solid manure. Quantities of gypsum are sprinkled over liquid manure wherever it is exposed, to fix free ammonia, which would otherwise volatilise and pass away in the atmosphere.

A point worthy of careful consideration is the placing of the various compartments of the steading in such relation to each other that there may be no unnecessary moving of food, manure, or dairy produce, so that time in performing the various operations going on in the steading may as far as possible be economised. The straw-barn should be near the centre of the steading, and the classes of stock receiving most straw accommodated nearest

to the straw-barn. The root-stores should be easily accessible from the cattle compartments, the hay-store from the stable, the dairy from the cow-house, and the stack-yard from the threshing-mill and straw-barn. The cart and implement sheds should be near to the stable.

In close steadings most careful attention should be given to *ventilation*, so as to secure a sufficient current overhead to keep the atmosphere pure and equable without allowing draughts to play directly upon the animals. Besides stone and bricks, concrete—1 part of stale Portland cement to 6 parts of broken stones or pure gravel (free from earthy matter)—is now largely employed in the construction of farm buildings, notably servants' cottages. Galvanised corrugated sheet-iron is extensively used in roofing courts for cattle. Covered stack-yards have not come into use, as was at one time expected, but large hay-barns, roofed with corrugated iron, are now very common, and are a valuable acquisition to farm-steading.

On the American continent farm buildings are generally constructed of wood. It is common there to find all the compartments of the farm-steading grouped under one roof, which is often of great dimensions.

**Farmer, RICHARD, D.D.**, a well-known 18th-century scholar, was born at Leicester, August 28, 1735, and in 1753 was entered a pensioner of Emmanuel College, Cambridge, where four years later he graduated a senior optime. Appointed classical tutor of his college, he took orders, and served the curacy of Swavesey, a village 9 miles from Cambridge. On Dr Johnson's visit to Cambridge the two scholars had a 'joyous meeting,' and ever after kept up the most friendly relations. Dr Farmer became a member of the famous Literary Club, and helped Johnson with Cambridge notes for his *Lives of the Poets*. He soon abandoned his projected history of Leicester, and published in 1767 his only work, the once famous *Essay on the Learning of Shakespeare*, which showed that the great dramatist derived his knowledge of the ancients from translations, having often preserved the phraseology and even the errors of the translators. In 1775 Farmer was elected to the mastership of Emmanuel College, and in 1778 became chief-librarian to the university. In 1780 he obtained a prebendal stall at Lichfield, in 1782 at Canterbury, which he exchanged in 1788 for a residentiary prebend in St Paul's. The remaining years of his life he divided betwixt residence in London and at Cambridge, beloved alike by the members of his college and by London men of letters for his geniality and his brilliant talk over a pipe of tobacco and a bottle of port. He was careless of his appearance, an inveterate collector of old books, and habitually indolent—a failing which alone prevented his making a figure in literature. He died September 8, 1797.

**Farmers-general** (Fr. *fermiers-généralx*) was the name given before the Revolution of 1789 to the members of a privileged association in France, who farmed or leased the public revenues of the nation. This system of tax-gathering became general in France from the year 1546, when Francis I. let out the *gabelle* or salt-tax in this way. The privileges of the position were sold to the highest bidder; but they were largely in the hands of the king's favourites. The powers, rights, and duties of the class were defined by special decrees; but, however severe may have been the fiscal laws against fraud and contraband, it is notorious that shortly before the Revolution abuses of the most flagrant description had demoralised the system and the men. During the Revolution most of these odious tax-gatherers perished on the scaffold, the innocent

among them being occasionally confounded with the guilty. Farmers of the revenue were an institution of ancient Rome (see PUBLICANS). Tolls on roads and duties of various kinds were at one time farmed also in Great Britain. See MONOPOLY.

**Farm-servants.** See LABOURERS.

**Farnborough**, a village on the east border of Hampshire, 32 miles SW. of London, contains part of the camp of Aldershot (q.v.). Near it is Farnborough Hill, the residence of the Empress Eugénie, beside which is the mausoleum whither the remains of her husband and her son were removed from Chisellhurst in 1888.

**Farne, Fearn, or Fern Isles**, or the **STAPLES**, form a group of seventeen islets and rocks (area, 80 acres; pop. 49 in 1881), some being visible only at low-tide, two to five miles off the north-east coast of Northumberland, opposite Bamborough. On House Island are remains of a Benedictine priory, dedicated to St Cuthbert (q.v.). The passage between the isles is very dangerous in rough weather; and on the group there are two light-houses. Here the *Forfarshire* was wrecked in 1838 (see DARLING, GRACE); and here, in 1843, the *Pegasus* met the same fate, when sixty persons were drowned.

**Farnese**, the name of an illustrious Italian family, three members of whom occupy a prominent position in history. ALESSANDRO FARNESE was raised to the papal see in 1534 as Paul III. (q.v.). He founded the duchy of Parma and Piacenza.—ALESSANDRO FARNESE (1546-92), son of the second duke, and one of the most skilful generals of his age, first distinguished himself at Lepanto (1571). Afterwards, as governor of the Spanish Netherlands, he captured Antwerp (1585) for Philip II., and compelled Henry IV. of France to raise the siege of Paris (1590).—ELIZABETH FARNese (1692-1766) became the wife of Philip V. of Spain in 1714, and was a warm supporter of the policy of Alberoni, Philip's minister.—The three pieces of antique sculpture (the Farnese Hercules, Flora, and Bull) were removed about 1790 from the Farnese Palace at Rome to the national museum at Naples.

**Farnham**, a town of Surrey, 38 miles SW. of London by rail, stands on the Wey, embosomed in hop-gardens. The principal feature is the old castle of the bishops of Winchester, first built by Bishop Henry de Blois, King Stephen's brother. Razed by Henry III., and afterwards rebuilt, it was garrisoned by Charles I., and restored in 1834 to its present state by Bishop Morley. A handsome Italian town-hall was built in 1866. Moor Park, the seat of Sir William Temple, with memories of Swift and 'Stella,' is in the vicinity; so, too, are the remains of Waverley Abbey (1123), whose *Annales Waverlienses* suggested to Scott the name of his first romance. The chief trade is in hops, a very fine variety being grown here. Pop. (1881) 4488. Toplady and Cobbett were natives. Aldershot Camp (q.v.) is 3 miles NE. of Farnham.

**Farnworth**, a township of Lancashire, 12 miles by rail ESE. of Liverpool. The manufacture of sail-canvas, watches, files, &c. is carried on. Pop. (1861) 8720; (1881) 20,708.

**Faro**, the capital of the Portuguese province of Algarve, on the south coast, behind three islands which form a good roadstead. It has considerable exports of fruits, cork, sumach, and fish. Pop. 8671. Faro was burned by the English in 1596, and partly destroyed by the earthquake of 1755.

**Faro**, a widely-known game of hazard, played with cards by a 'banker' against an indefinite number of players. It is so called from Pharaoh, the old name of one of the court cards.

**Faroe Islands** (Dan. *Faær-Øer*, 'sheep islands'), a Danish group of islands, twenty-two in number, of which seventeen are inhabited, lying between the Shetlands and Iceland, 200 miles NW. of the former, in 61° 25'—62° 25' N. lat., and 6° 19'—7° 40' W. long. Their area is 513 sq. m., and their population (1850) 9150; (1890) 12,954. The islands are the remains of a single continuous plateau, originally trenched by deep erosion valleys, which, being inundated by the sea during a subsequent era of depression of the land, became converted into fjords and sounds. Geologically they consist of volcanic rocks, horizontally disposed beds of basalt predominating. Seaward they present rugged precipitous cliffs, ranging in height from 1000 to 2300 feet, whilst inland they rise into flat-topped pyramidal mountains, which attain maximum elevations of 2502 feet in Skellingfeld in Strömö, and of 2895 feet in Slattatind in Österö. The currents that run through the sounds are swift and dangerous; storms and whirlwinds are frequent; and the harbours and anchorages in the fjords and bays are not very secure, but, on the other

hand, nearly always free from ice. For, though the climate is misty and moist, the winters are comparatively mild. Peat and coal are used for fuel. Trees there are none, owing to the storms; timber for building purposes is imported from Norway. Tillage is confined to the cultivation of a few vegetables, and attempts, not always successful, to grow barley. The principal sources of wealth are sheep-farming, wild-fowling, and fishing; and the products of these, including wool, feathers, salt and dried fish, train-oil, and skins, are the principal exports, sent for the most part to Denmark. The largest islands are Stömö (23 miles long by 8 broad), Österö, Vaagö, Sandö, and Süderö. The capital of the group is Thorshavn in Strömö, with 984 inhabitants; the town of Kirköb, on the same island, was formerly the seat of a bishop. The inhabitants, of Norse descent, are simple and grave in their manners, and industrious in their habits. They speak an Old Norse dialect, though modern Danish is the language of law-courts, churches, and schools. They belong to the Lutheran Church. Since 1854 the islanders have enjoyed a certain amount of self-government under the control of three Danish administrative officers, who officiate as governor, police-inspector, and judge respectively. They send two representatives to the Danish parliament, one to the Upper House, chosen by the

popular assembly of the islands, the other to the Lower House, elected directly by the people themselves. From the time of their first colonisation in the 9th century the Faroe Islands belonged to Norway down to 1380, in which year they passed to Denmark. The natives possess a number of ancient epical ballads (*kvæði*), the most important group being the *Sjórdar Kvæði*, or songs of Sigurd (ed. with grammar, glossary, &c. by Max Vogler, i. Paderborn, 1877). The chief names in the native literature are Svabo (1746-1824); N. Mohr (1742-90); J. H. Schnoter (1771-1851), the first to devote much attention to the prose literature—some of the folk-stories he collected are to be found in *Antiquarisk Tidsskrift* (1849-51); the patriotic Poul Nolso (1766-1809), whose *Vogellied* is the most popular modern poem in the Faroe dialect; and Venzel Ulrik Hammershaimb (born 1819), editor of *Færoiske Kvæder* (i. and ii. Copenhagen, 1851-55), in the well-known *Nordiske Literatur-Samfund*. The last prepared the first grammar in 1854, and in the pages of *Dimmalætting*—the only newspaper of the islands, but printed mostly in Danish—a new translation into the modern dialect of the so-called *Færeyingasaga*.

**Farquhar, GEORGE**, was born at Londonderry in 1678, and received his education at Trinity College, Dublin, where, although he did not take any degree, he secured among his comrades the reputation of a wit who was a spendthrift of his witticisms. When he left the university he was engaged as an actor at one of the Dublin theatres, but, like most dramatists who have figured on the stage, he proved but an indifferent performer. Playing a part in Dryden's *Indian Emperor*, and forgetting that he wore a sword instead of a foil, he accidentally wounded a brother-performer, and was so shocked by the occurrence that he at once quitted the boards. Accompanied by the actor Wilks, he proceeded to London, and shortly after received a commission in the regiment commanded by the Earl of Orrery, which was then stationed in Ireland. Urged by Wilks, and perhaps stimulated by the gaiety and leisure of a military life, he in 1698 produced his first comedy, entitled *Love and a Bottle*, which proved a success. Two years afterwards his *Constant Couple* appeared, which met with a brilliant reception, and to which he wrote a sequel, called *Sir Harry Wildair*. In 1703 he produced *The Inconstant*, founded on the *Wild-geese Chase* of Beaumont and Fletcher, a version in which all the coarseness, and none of the poetry, of the elder dramatists is retained. Having married in the same year, he fell into serious pecuniary difficulties, sold his commission, and, struggling with adverse fortune, succumbed. He died of decline in 1707, leaving 'two helpless girls' to the care of his friend Wilks. During his last illness he wrote the best of his plays, *The Beaux' Stratagem*—in six weeks, it is said—and died while its wit and invention were making the town roar with delight. Another popular play, *The Recruiting Officer*, had been produced in 1706.

Farquhar is one of the best of our comic dramatists, although Pope called him 'a farce writer.' He is less icily brilliant than Congreve, and possesses on the whole more variety and character than any of his compeers. He had wit in abundance, but he had humanity too. He was a tender-hearted and somewhat melancholy man—'very splenetic, and yet very amorous.'

**Farr, WILLIAM**, statistician, was born at Kenley, in Shropshire, November 30, 1807. He studied medicine at Paris and London, and afterwards gave his attention mainly to medical statistics and the questions connected therewith. In 1839, two years after the registration of deaths, and of the causes of

death was commenced in England, Farr received an appointment in the Registrar-general's Office in London, where he eventually became superintendent of the statistical department, a post which he held until 1880. He died in London, 14th April 1883. His chief books are *Tables of Lifetimes, Annuities, and Premiums* (1864); *English Reproduction Table* (1880); and *Net Premiums for Insurance against Fatal Accident* (1880). His *Vital Statistics*, a memorial volume, appeared in 1885.

**Farragut, DAVID GLASGOW**, the greatest of American seamen, was born of Spanish origin, near Knoxville, Tennessee, 3th July 1801. Entering the navy in 1810, he became a lieutenant in 1825, commander in 1841, and captain in 1855. On the outbreak of the civil war he held by the Union, and in 1862 was given the command of the armament of wooden steamers and mortar-boats fitted out for the capture of New Orleans. The approach to the city was defended by two strong forts, a number of Confederate steamers and an ironclad ram, besides chains stretched across the river, whilst sharpshooters and fire-rafts had been prepared to harass the attacking force. After the forts had been shelled for six days and nights without effect, Farragut decided to force the passage in the darkness, and actually carried through all but three of his vessels, in spite of the terrible raking fire poured in as they passed the opening made in the boom. The Confederate fleet was sunk or burned, and, on the 25th April, the last batteries having been silenced, the city was evacuated, and Farragut's men landed. For many months thereafter he was employed on the Mississippi, until in July 1863 the last fort surrendered, and the entire river was open to navigation. In July 1862 he had been commissioned rear-admiral, and in 1864 he returned to the Gulf, where on 5th August he fought the battle of Mobile Bay, destroying the enemy's gunboats and a powerful ironclad ram; a few days later the forts surrendered, and the port of Mobile was thenceforth closed to blockade-runners. In December he was made vice-admiral, the grade being created for him by congress, as was also the rank of admiral, to which he was raised in 1866. He died at Portsmouth, New Hampshire, 14th August 1870. There is a colossal bronze statue of Farragut in Washington, and another, of heroic size, in New York. See the Life by his son (New York, 1879).

**Farrant, RICHARD**, musician, was born about 1530, entered the Chapel Royal, became organist of St George's Chapel in 1564, returned to the Chapel Royal in 1569, whence he retired in 1580, and died in 1585. His name is best known in connection with the anthem, 'Lord, for Thy tender mercies' sake,' and a chant based on it, which, however, seem certainly not to be his. He actually did compose a full morning and evening service, and two anthems which have been printed, with parts of other services.

**Farrar, FREDERIC WILLIAM, D.D.**, Archdeacon of Westminster, was born in Bombay, 7th August 1831, and graduated at London University and at Cambridge, where he was fourth classic. Ordained in 1854, he was for many years a master at Harrow, and in 1871-76 head-master of Marlborough College; in 1868 and 1874-75 he was a select preacher before the university of Cambridge, in 1869-73 honorary chaplain to the Queen, and afterwards a chaplain-in-ordinary. He became canon of Westminster and rector of St Margaret's in 1876, and archdeacon in 1883. An eloquent preacher, he has taken an active part in temperance reform. As an author, his industry and productiveness have been equalled only by the remarkable popularity of some of his writings, which include, besides *Eric* (1858) and other stories of school-life, and his earlier

works on philology and education, *The Witness of History to Christ* (Hulsean Lectures for 1870); *The Life of Christ* (2 vols. 1874), which passed through twelve editions in as many months; a *Life of St Paul* (2 vols. 1879); *The Early Days of Christianity* (2 vols. 1882); *The History of Interpretation* (Bampton Lectures for 1885); and *The Lives of the Fathers* (2 vols. 1889). He has also contributed largely to the magazines, and published several volumes of sermons; among these last is his *Eternal Hope* (1878), which denied the probability of eternal punishment. *Darkness and Dawn* (1892) is a story of Nero's days. In 1890 he became chaplain to the House of Commons. He has contributed to this work the articles JESUS CHRIST and PAUL. Archdeacon Farrar is an enthusiastic advocate of temperance.

**Farrier**, a shoer of horses, who formerly also treated their diseases. See HORSE-SHOEING, VETERINARY MEDICINE.

**ARMY FARRIERS.**—In each regiment of British cavalry there is a farrier quartermaster-sergeant (formerly farrier-major), with eight sergeant-farriers and eight shoeing-smiths, who attend to the shoeing of the horses and their treatment when sick, subject to the directions of the veterinary surgeon. The daily pay of the three ranks is 4s., 2s. 10d., and 1s. 10d. respectively. They wear as a badge on the sleeve a horseshoe, in hoisted for the shoeing-smiths, and in gold for the farriers, who rank as sergeants and wear Chevrons (q.v.). All other mounted troops have farriers and shoeing-smiths in proportion to the number of their horses.

**Fars**, or **FARSISTAN** (anciently *Persis*), a province of Persia, bordering on the Persian Gulf, rises from the steep coast in a succession of broad terraces. The coast zone or 'hot country,' the productiveness of which is greatly dependent upon the rainfall, is backed by the 'land of the passes,' behind which comes the 'cold country'; the interior belongs to the Iranian plateau. The mountain chains, lying parallel to the coast, embrace numerous fertile valleys, rich in pastureage and vines and fruit-trees. Amongst the mountains are several lakes, the largest Lake Bakhtegan (q.v.). The rivers are small. The climate varies with the different districts. The principal products of the province are fruits, dates, tobacco, cotton, silk, and excellent wine. Area, about 53,500 sq. m. The population, the exact number of which is not known, is very sparse. The capital of Fars is Shiraz; the port, Bushire, on the Persian Gulf.

**Farthing** (Sax. *feorſing*, from *feorð*, 'fourth'), an English copper coin equivalent in value to the fourth part of a penny. In accordance with representations made to the government by Dean Swift for the improvement of the coinage, certain pattern farthings were struck in the years 1713-14, known as 'Queen Anne's farthings.' Five distinct varieties are known to exist. The scarcity and value of the pieces, which are indeed not rare amongst collectors, has been strangely exaggerated.

**Farthingale**, or **FARDINGALE** (Old Fr. *vertugalle*, from Span. *vertugada*, 'a hooped petticoat'). See CRINOLINE.

**Farukhabad**, a city of the North-west Provinces of India, near the right bank of the Ganges, 83 miles N.W. of Cawnpore. It is a clean and healthy place, with a considerable trade, and a population (1881) of 62,437.—The district of Farukhabad belongs to the alluvial plain of the Doab, the soil being for the most part high-lying, sandy, and infertile. Area, 1719 sq. m.; pop. 907,608. The most important crops are potatoes, indigo, and sugarcane. The capital is Fatehgarh. The ruins of Kanauj, the capital of a powerful Hindu kingdom, still exist within the district.

**Fasano**, a town of Italy, in the province of Bari, 35 miles N.W. of Brindisi by rail, in the midst of an olive district. There are numerous oil-presses in the town and neighbourhood. Pop. 13,941.

**Fasces** were bundles of rods usually made of birch, but sometimes of elm, with an axe (*securis*) projecting from the middle of them, which were carried before the chief magistrates of ancient Rome as symbols of their power over life and limb. They were borne by the lictors, at first before the kings, in the time of the republic before consuls and pretors, and afterwards before the emperors. Their number varied, a consul and a proconsul in his province having twelve, a praetor six, but within the city only two. Valerius Publicola introduced a law that within the city the axe should be withdrawn, except in the case of a dictator, who was preceded by twenty-four lictors, bearing as many fasces. Publicola also made the fasces be lowered at the assemblies of the people, as an acknowledgment of their supreme power.

**Fascia**, in Architecture, a flat space or band between moldings. See ENTABLATURE.

**Fasciation** is a form of monstrosity not uncommon in plants. The growing apex loses its usual conical shape and becomes greatly extended in one diameter, so as to produce a broad band-shaped growing-point. This may continue to widen until it has reached many times the normal breadth without any proportional increase in thickness, and often becomes thrown into irregular folds, the leaf arrangement becoming correspondingly confused. Cases of fasciation occur not unfrequently in the ash-tree, the auricula, daisy, and other common plants, and constantly in the cultivated Cockscomb (q.v.). Such growths are with Welsh Gypsies an object of superstitious reverence.

**Fascination** (Lat. *fascinio*, 'I bewitch,' doubtfully akin to Gr. *baskainō*), an interpretation of the fatal influence of some serpents over their destined prey. Kalm and others describe how the rattlesnake fixes a squirrel with its lidless eye, and so far demoralises the victim that it drops into the distended mouth. Le Vaillant describes the convulsions and finally the death of a shrike, paralysed by fear of a serpent at a distance of nearly four feet. Dr Andrew Smith reports that the non-venomous South African tree-snake (*Bucephalus viridis*) gathers quite a circle of victims. Ellis notes the interesting fact that an object pushed between the eye of the snake and a victimised frog broke the spell. In spite of many observations which suggest mesmeric or hypnotic influence, against which there is no strong improbability, most naturalists regard so-called fascination as equivalent to fear. In panic animals may undoubtedly become paralysed or stupid, or lose the usual power of co-ordinating their actions. See EVIL EYE, SERPENT.

**Fascines** (from Lat. *fascis*, 'a bundle') are brushwood fagots bound together with wire, yarn, or withes. They are 18 feet long and 9 inches in diameter, used for revetting the steep interior slopes of field-works and for other military purposes, such as roofing magazines, Casemates (q.v.), Blockhouses (q.v.), &c., when timber cannot be procured. A double row covered with earth several feet thick is almost bomb-proof. They also make a very strong stockade, and can be used in bridging operations and road-making. Cut into six-foot lengths, they are often carried by the men of an assaulting column to fill up the ditch of a work or lessen its depth. Five men can make a fascine in an hour.

**Fasciola**. See FLUKE, TREMATODES.

**Fasher**, a province of Dai-fû (q.v.).

**Fashion and Fashionable**, terms applied to occupations, pursuits, education, and manners, as well as to most of the luxuries and necessities of modern civilised life, denote an unending series of changes and modifications which are most marked and most apparent in the department of dress. Such variations of costume were unknown to most nations of the ancient world, and among the Romans only influenced the accessories of the toilet. The unchanging East is as unchanging in its dress as in everything else, and the fashions

to which savage tribes uncompromisingly adhere remain unaltered for long periods. In some remote districts of European countries peasants still dress in the costume brought two or three hundred years ago by the local nobility from court, and the smock frock of the English agricultural labourer is a relic of Saxon times. The natural conservatism of man often throws strong light upon long-forgotten social history, and nowhere more than in the survivals in modern costume. Thus, as Mr Tylor points out, there is much to be learnt from so quaintly cut a garment as the modern evening

1, Flemish (1341); 2, French (1410); 3, German (1530); 4, Spanish (1550); 5, French (1500); 6, 7, Beginning of 17th century.

dress-coat. 'The cutting away at the waist had once the reasonable purpose of preventing the coat skirts from getting in the way in riding, while the pair of useless buttons behind the waist are also relics from the times when such buttons really served the purpose of fastening these skirts behind; the curiously cut collar keeps the now misplaced notches made to allow of its being worn turned up or down; the smart facings represent the old ordinary lining; and the sham cuffs now made with a seam

round the wrist are survivals from real cuffs, when the sleeve used to be turned back. Thus, it is seen that the present ceremonial dress-coat owes its peculiarities to being descended from the old-fashioned practical coat in which a man rode and worked.' Again, the English clergyman's bands are directly traceable through intermediate stages to the wide collars which everybody wore in Milton's time, the very name of which also survives in our word *bandbox*. And it is said that the

modern cylindrical hat is the indirect descendant of the Puritan steeple-crowned hat, carried across the Atlantic by the Pilgrim Fathers, thence again to France, when Benjamin Franklin and the young Republicans were the height of the fashion, and by the French manipulated into the hat which they have given to all the world.

The Romans spread their dress with their civilisation over Europe, and it was gradually modified by the close-fitting garments of the races of the north till the two styles were united in the 5th century; but fashion in its modern sense cannot be said to

begin till the 14th century. Then complaints first arise of clothes being cast aside for others of newer shape and cut. It must be remembered that till the 19th century men's clothes were as delicate in colour and as rich in material as women's; Pepys records in his diary how he had his wife's gowns cut up into waistcoats for himself. The change during the 14th century from close-fitting tunic and hose to long, loose garments trailing on the ground is even more startling than the outcrop of steeple-like headgear which distinguished the ladies of the 15th century.

The sumptuary laws of the 13th, 14th, 15th, 16th, and 17th centuries clearly show that dress was originally a symbol of rank, strictly prescribed for the various classes of society. An early French law complains of each man clothing himself as he pleased, without reference to his rank, so that it was impossible to tell from his dress whether he was a prince, nobleman, citizen, or labourer. In modern days this state of things is fulfilled to the letter, though costume still retains its old significance in the uniforms of the army and navy, of policemen and postmen, in the lawyer's wig and gown, the judge's robe, the bishop's lawn sleeves, and the university student's cap and gown, all of which, as Mr Herbert Spencer remarks, are worn by people whose office it is to uphold established arrangements in church and state. The railway companies and the Post-office impose a uniform on their employees, the maid-servant (in Britain) wears a cap and apron, and the waiter a black suit, but the only class who at all times voluntarily mark themselves off from other men are the clergy. Political and religious opinions have been at times symbolised by dress, as with the Puritans and Quakers; and instances of such distinguishing marks as the tricolor of France, the white cockade of the Bourbons and the Stuarts, the blue and green of the factions in the streets of ancient Constantinople, the orange and green of Irish political parties, and the blue and buff of English elections might be multiplied indefinitely. Dress attained its highest point of significance in France during the last half of the 18th century, when it marks unmistakably the various stages of the Revolution. Rousseau's *Émile* and *Nouvelle Héloïse* and Goethe's *Werther* brought sentimentality into fashion; women's hair was dressed in *bandeaux d'amour* or *poufs de sentiment*; and Marie Antoinette and the ladies of her court sought to return to the simplicity of nature by masquerading in the Trianon attired as shepherdesses and milkmaids. The works of Montesquieu and Voltaire had created an admiration for England, and the courtiers of Versailles dressed themselves like English foxhunting squires, while their wives and daughters got themselves up à l'Anglaise in coats with cuffs, collars, and facings, beaver-hats, and cravats. As the political turmoil increased, fashionable attire grew more and more eccentric and multifarious, till at last republican institutions triumphed, and the women of France began to clothe themselves as like as possible those of Greece and Rome both in style and scantiness. They discarded costly materials, and shivered through the winter months clad in a few yards of muslin. Men wore a combination of antique and romantic costume invented by the painter David, which was finished off with Hungarian boots. The gorgeous and stately dress of the courts of Louis XIV. and Louis XV. had disappeared with the old régime. At the present time the fashions for women in all civilised countries are set by Paris; for men, though not so exclusively, by London.

One marked feature of the ever-changing kaleidoscope of fashion is its tendency to revolve in cycles. The widely-distended skirts of the 16th century reappear in the 18th and 19th centuries after periods of straight-falling folds; the piles of false hair, artificial flowers, feathers, and jewelry which reached their greatest height on ladies' heads about 1780 have had their modified counterpart in the modern chignon; men's nether garments are by turns skin-tight or loose and full; and the voluminous folds of muslin in which they swathed their necks at the beginning of this century recall in some degree the ruffs of Queen Elizabeth's courtiers. Cycles of alternate luxury and simplicity have also distinguished all ages, though

the simplicity of fashion is often more apparent than real. There can be little doubt that fashions change more quickly each decade, a fact due in great measure to increased facilities of communication, while the triumph of democracy is shown by their universal adoption by all classes. The question cannot but arise whether in this continual variation the most advantageous and artistic costumes for men and women may not at last be found and kept, but the probabilities seem to be against such a conclusion. Lotze in his *Microcosmus* starts the theory that we prolong the consciousness of our personal existence into any foreign body brought into relationship with the surfaces of our own body, so that we feel ourselves grow taller with our high headgear, move with our fluttering laces and ribbons, and derive vigour from the feeling of resistance arising from a tight band or belt. At the same time it is generally allowed that we are more alive to a new sensation than to one which has been long in the field of consciousness, for, from the very fact that it is unusual, our attention is continually directed to it, while a well-known sensation loses its first intensity and the power of directing our thoughts to itself. In order, therefore, that our clothes may yield us the maximum of pleasant feeling which Lotze says we derive from them, they must not be too familiar in shape, colour, and cut—i.e. we must not only have new clothes, but new styles of clothes. But a volume would be required to determine whether this theory satisfactorily accounts for all the changes of fashion.

See Fairholt, *Costume in England* (new ed. 1885); Planché, *Cyclopedia of Costume* (1876-79); Chalmers, *History of Fashion in France* (Eng. trans. 1882); Jakob von Falke, 'Kostüm und Mode,' in *Zur Kultur und Kunst* (Vienna, 1878); Herbert Spencer's *Ceremonial Institutions* (1879); and the articles BLOOMER COSTUME, CRINOLINE, HAT, BEARD, WIG, FAN, TATTOOING, &c.

**Fashoda**, a town in the Suddik country, on an island in the White Nile, 60 miles below the mouth of the Sobat tributary. It was founded by the Egyptians, and made capital of a province in the Egyptian Soudan.

**Fast** (a word common to the Teutonic tongues, which Grimm derives from a root signifying primarily to hold, keep, observe, and hence to restrain one's self; Lat. *sejūnum*, Gr. *nástain*, Heb. *tsom*) is the word used to express a certain self-imposed restraint with respect to the nourishment of the body. The abstinence enforced may be either partial, when the restriction is confined to certain articles of food, or total, when all sustenance is dispensed with for a specified time. The origin of the custom seems to be coeval with man's first experience of the salutary influence which abstinence exercises on the health, and with his more or less instinctive consciousness of the necessity of retaining the body in due subjection to the soul. By degrees, the self-mortification which it implied raised it into a sacrifice offered to the Deity; it became a religious observance, was surrounded with rites and ceremonies, and finally bore the stamp of a divine law. Climate, the habits of a people, and their creed gave it at different periods different characteristics; but it may be pronounced to have been a recognised institution with all the more civilised nations, especially those of Asia, throughout all historic times. We find it in high estimation among the ancient Persians of Iran. It formed a prominent feature in the ceremonies of the Mysteries of Mithras, and found its way, together with these, over Armenia and Asia Minor, to Palestine, and northward to the wilds of Seythia. The ancient Hindus, in accordance with their primeval view—which they held in common with

the Parsees—of heaven and hell, salvation and damnation, of the transmigration of the soul, and of the body as the temporary prison of a fallen spirit, carried fasting to an unnatural excess. Egypt seems to have had few or no compulsory general fasts; but it is established beyond doubt that for the initiation into the mysteries of Isis and Osiris temporary abstinence was rigorously enforced. (For Buddhist usages, see **BUDDHISM**.) That Greece observed and gave a high place to occasional fast-days, such as the third day of the festival of the Eleusinian mysteries, and that, for instance, those who came to consult the oracle of Trophonius had to abstain from food for twenty-four hours, is well known. It need hardly be added that the Romans did not omit so important an element of the festivals and ceremonies which they adopted from their neighbours, though with them the periods of fasting were of less frequent recurrence.

As to the Semitic races, although we find the people of Nineveh undergoing occasional fasts, to which even animals were made to conform, yet the Mosaic law set apart one day only in the whole year for the purpose of fasting. The 10th day of the seventh month (Tishri), called 'the Day of Atonement' (Yom Kippur), or, as the holiest of the whole year, 'the Sabbath of Sabbaths,' was ordained for 'the chastening of the *Nephesh*,' which the traditional law explains as meaning the strictest and most rigorous abstinence from all food or drink, as also from washing, anointing, the putting on of sandals, &c., from the sunset of the ninth to the rising of three stars on the evening of the tenth day. In process of time, five days of compulsory fasting were added, in commemoration of certain days of humiliation and national misfortune—viz. the 17th of the fourth month (Tammuz), as the anniversary of the taking of Jerusalem both by Nebuchadnezzar and Titus; the 3d of the seventh month (Tishri), when Ishmael had killed Gedaliah, the Jewish governor appointed by the Babylonians; the 10th of the tenth month (Tebeth), in remembrance of the siege of Nebuchadnezzar; the 13th of the twelfth month (Adar), the fast of Esther, and the day most rigorously kept next to the great Day of Atonement; and the 9th of the fifth month (Ab), the anniversary of the destruction of the first temple by Nebuchadnezzar and of the second by Titus. The community loved to express their penitence for sin, or their grief on the death of great men, by occasional fastings, which were also considered an efficient means of averting the divine wrath, of insuring victory over an enemy, or of bringing down rain from heaven. Besides, fasting was not unfrequently resorted to by those who wished to free their minds from all hindrances to meditation, as in the forty days of Moses (Exod. xxxiv. 28), or the fast of Daniel. In later times, when, after the destruction of the temple, sacrifices had ceased, fasting, as causing a decrease in the flesh and fat of the individual, was considered to be in some degree a substitute for the animal which had formerly been offered up by the priest. From a means to repentance and inward purification, it became an end and a virtue in itself, an abuse, indeed, neither unknown nor undenounced even in the days of the prophets. Many new fasts were superadded from time to time, but they soon fell into oblivion; and over and above the six already mentioned but few entire days are now observed by the orthodox, and these merely of a local character. Fasting, with the Jews, always implies entire abstinence, and lasts, except on the Day of Atonement and the 9th of Ab—when the sunset of the previous evening is the sign for its commencement—from the break of the day to the appearance of the first three stars. Sackcloth and ashes, the garb

of the penitent in ancient times, are no longer worn; but the deepest mourning is visibly expressed by many ceremonies in the Jewish synagogues and homes on the 9th of Ab. Several half-days of fasting have also survived. The individual is bound to celebrate by fasting the anniversary of the death of his parents, his own wedding-day until the performance of the marriage-ceremony, and the birth of his first-born male child (up to its thirteenth year, when the duty falls upon the latter himself), and on the day preceding the Pesach (Pascha), in commemoration of the sparing of the Israelite first-born in Egypt. The Sabbath causes the postponement of any fast—that of the Day of Atonement only excepted—which may happen to be coincident with it; and children—girls up to their twelfth, boys to their thirteenth year—women with child, and the sick are exempted from the observance.

In the time of Christ, fasting, as we have seen, was held in high estimation. The Mondays and Thursdays—the market-days, on which the judges sat, and the law was read in the synagogues—were especially set aside for this purpose by the Pharisees. The Essenes fasted even more frequently. The Sadducees alone took exception to this rite, and were therefore considered ungodly. Christ himself neither approved nor disapproved of the custom, but, as in all matters of ceremony, allowed his disciples, Jews and Gentiles, to act according or contrary to their old habits. He is distinctly against such a *commandment*, and even excuses those who did not fast; his own abstinence from food for forty days was like that of Moses, entirely an individual act. Roman Catholics maintain that all the words of our Lord, which to Protestants appear to discountenance the obligation of fasting, are directed exclusively against the ostentations and self-reliant fasts of the Pharisees. They even understand the language which he used in condemning the practice of the Pharisee fasters as containing a direct exhortation to his own disciples—not that they should abstain from fasting, but that they should fast with suitable dispositions. They hold, moreover, that in exempting his disciples from fasting he had regard only to the actual time of his own presence among them. It was incongruous, he said, that the children of the marriage should fast as long as the bridegroom was with them; but, he added, 'the days will come when the bridegroom shall be taken away from them, and then shall they fast in those days' (Mark, ii. 20; Matt. ix. 15). Hence they infer that from the time of our Lord's ascension the practice of fasting became obligatory on his disciples, the temporary cause of the exemption hitherto existing having ceased.

During the first centuries of Christianity voluntary fasts were frequent enough; and fasts were considered a befitting preparation for holy acts and feasts, for ordination and baptism. An annual fast generally observed by all from a very early date was that of the forty hours, from Friday afternoon to Sunday morning, during which Christ lay in the sepulchre. But during the first six centuries the difference in the various Christian communities in this matter was very great. The Montanist heretics were especially rigorous in their fasts. Bishops and councils gradually fixed the times and seasons for the whole of Christendom. The forty hours had gradually become forty days, called the *Quadragesima*; and the Council of Orleans in 541 made it binding upon every Christian not to eat any meat during this time, save only on the Sundays. The eighth council at Toledo in the 7th century declared those who ate meat during Lent sinners unworthy to partake in the resurrection. From the 8th century to the 11th,

when a gradual reaction set in, the laws of fasting and the punishments awarded to the transgressors became stricter and stricter; interdiction and excommunication were among the penalties. By degrees fasts had become so numerous and different in kind that they were divided into—(1) *Jejunium generale* (a fast binding for all); (2) *Consuetudinarium* (local fast, &c.); (3) *Penitential* (atonement for all transgressions); (4) *Votivum* (consequent upon a vow); (5) *Voluntarie* (for the better carrying out of an undertaking). These, again, were kept as either (1) *Jejunium naturale* (an entire abstinence from food or drink, especially in preparation for the reception of the Eucharist); (2) *Abstinencia* (certain food only being allowed, but several times a day); (3) *Jejunium cum abstinencia* (the same food, but which must be taken once a day only); or (4) *Jejunium sine abstinencia* (all kinds of food, but only once a day). The food prohibited on partial fast-days included, during certain periods, not only the flesh of quadrupeds, fowl, and fish, but also the 'lacticinia'—i.e. all that comes from quadruped and bird, as butter, eggs, milk, &c.

Fasts gradually developed in the Roman Church into—(1) Weekly fasts, of which Friday, as the day of the crucifixion, seems to have been early and generally observed. To this was added the Wednesday, as the day on which the death of Christ was resolved upon. At a synod in Spain in the beginning of the 4th century the Saturday was superadded; but this innovation met with great opposition, especially in the East. (2) Vigils, originally night-services observed by the first Christians on the eve of Sundays and festivals, partly in imitation of the Jewish custom of celebrating the entrance of the Sabbath and of festivals on the evening of the previous day, and partly from fear of the danger to which a service in the daytime would have exposed the early converts. Although these night-services became unnecessary in the course of time, they were still continued up to the 4th century, when, owing to the abuses to which they led, they were abolished, or rather transformed into fast-days, kept on the eve of great festivals in honour of Christ, the Virgin, Saints, and Apostles. (3) The great or forty days' fast (Quadragesimal fast), the most important and most rigorously enforced of all. The forty hours of fast, in commemoration of the forty hours during which Christ's body lay in the tomb, gradually expanded to forty days, as mentioned before, in pious allusion to the forty days of Moses, Elijah, Christ, the forty years' sojourn in the desert, or the forty camps—all considered typical; and the fasting became severer the nearer Passion-week itself approached, in which many other signs of mourning and contrition were generally exhibited. (4) The Quarter fasts on the Wednesdays, Fridays, and Saturdays in one week of each season, in imitation of the four Jewish fasts in the fourth, fifth, seventh, and tenth months.—There were still many other fasts, such as those of ordination, &c., but these had only a temporary existence, and do not fall to be treated here. Nor can we enter into the various dispensations granted by the church, or the special pastoral letters generally issued before Quadragesima, nor into the variations in the observance of fasts and fasting in our own days; we can only add that they have in a great measure lost their former severity, and that only partial abstinence is the rule in all cases. More must not be taken than one full meal, and that not before mid-day, nor consisting of flesh meat. Besides this a collation of about eight ounces of fruit, vegetables, bread, or small fishes may be taken. The modern meaning of this word was originally due to the

slight refreshment in the ancient monastic discipline, taken just before the reading of the 'collations'—i.e. conferences (of Cassian) and such other works. In spite of its diminution of the former severity in the practice of fasting, the opinion of the church held in former days, that fasting is meritorious and conducive to the salvation of the soul, has undergone no change.

In the Greek Church fasting was and is kept with much greater severity, the non-observance of it being the least venial of sins. The days here extend over almost three-quarters of the year. The principal ones are the Wednesdays and Fridays—with a few exceptions—throughout the whole year; the great Easter fast lasting forty-eight days; that of Christmas, thirty-nine days; that in honour of the Virgin, fourteen days; and that of the Apostles, beginning on Monday after Trinity, and extending to the 29th of June. Besides those smaller fasts of preparation, which correspond to the vigils of the Roman Church, they have many more occasional fasts, which we, however, must omit here.

The Church of England considers fasting a praise-worthy but by no means obligatory custom. Hook, in his *Church Dictionary*, explains the distinction between the Protestant and the Roman Catholic view of fasting as consisting in this, that the Roman Catholic regards the use of fasting as an imperative means of grace, the Protestant only as a useful exercise preparatory for the means of grace. In proof how much the Church of England has left the question of fasting to the conscience and discretion of her members, it may be observed that she has neither defined the mode or degree of fasting, nor anywhere given a positive command to fast. The days named by the English Church as seasons of fasting or abstinence are the forty days of Lent (q.v.), including Ash-Wednesday and Good Friday; the Ember (q.v.) days; the three Rogation (q.v.) days; all the Fridays in the year (unless Christmas Day fall on one); and the eves or vigils of certain festivals.

The sacramental *fast-days* so long observed in Scotland are now falling into disuse, and are already completely discontinued in such cities as Glasgow (1886) and Edinburgh (1887). The Scotch fast-day was instituted as a day for 'fasting, humiliation, and prayer,' and always fell upon some day of the week preceding the yearly or half-yearly *Communion Sunday*, or Sunday set apart in the Presbyterian churches for the dispensation of the Lord's Supper. It was observed exactly as a Sunday, with sermons in the churches and the complete cessation of business.

In the United Kingdom, on occasion of wars and public calamities, the sovereign has from time to time appointed by proclamation a day for a solemn national fast, humiliation, and prayer—as on 21st March 1855 (the Crimean war), and 7th October 1857 (the Indian Mutiny).

A few words remain to be said of the Mohammedan fasts. Islam, as an offspring of Judaism and Christianity, adopted this custom with many others from both churches. During the whole month of Ramadan, in which the Prophet brought the Koran from heaven, eating, drinking, smoking, smelling perfumes, &c. are strictly forbidden from daybreak till sunset; for the intervening nights, however, all these restrictions are removed. There are, besides, many voluntary fasts, expiatory like the 10th of Moharram, corresponding to the Jewish Day of Atonement, or for the averting of the divine wrath in sudden calamities, or as an indemnification for the omission of certain pious acts, as the pilgrimage, &c. See JEWS, MOHAMMEDANISM, MONACHISM, ASCETICISM.

ix. (1708-22); Fabricius, *Bibliogr. Antiquaria*; Muratori, *De Quatuor Temporum Jeuniis*, &c.; Siegel, *Alchristol. Alterthümer*; Walch, *De Jeunio Quadragesimali* (1727); Robert Nelson, *Fetters and Fasts of the Church*; and Liesmayr, *Die Entwicklung der Christlichen Fasten-disziplin* (1877).

**FASTING.**—By this term is meant the deprivation of food—the materials by which loss of matter and energy from the body is made good.

Food-stuffs may be divided into (1) oxygen, (2) water, (3) solid food-stuffs. For a discussion of the relationship of oxygen to the other food-stuffs, the reader is referred to the articles upon **RESPIRATION**, **METABOLISM**. There is now no doubt that it takes part in the constructive changes in the tissues, and for this reason it must be classified among the food-stuffs. Deprivation of oxygen rapidly results in death (see **ASPHYXIA**).

When water is withheld death occurs in the course of a few days. For the protoplasm of the tissues to undergo the chemical changes upon which its vitality depends, a certain proportion of water is essential, and when this is not present death ensues through the cessation of these changes.

It is more especially to the deprivation of *solid food* that the term *Fasting* is applied. The physiology of this condition has been most carefully studied in dogs, cats, and other of the lower animals, while one or two observations have also been accomplished in cases of voluntary fasts in man.

To understand the condition, it must be remembered that the energy required in the body is under normal conditions supplied by the various organic food-stuffs, which, entering the body in the condition of large and complex chemical molecules, are broken down and excreted as simpler bodies, and by their disintegration yield energy (see **METABOLISM**, **NUTRITION**). During fasting it is by the disintegration of the tissues of the body that the necessary energy is yielded. This energy is required not only for the production of mechanical work done by the body, but also for the production of heat, so that the temperature of the body may be maintained. Whenever, therefore, muscular exertion is severe, or when the individual is exposed to cold and has to produce large amounts of heat, then more energy must be forthcoming, and hence tissue waste is enormously increased. Whereas, if complete rest is maintained, and the animal is kept surrounded by air at a temperature approaching that of the body, the waste of tissue-substance is reduced to a minimum. From this it will be apparent that no conclusions of value with regard to the possible duration of life in the fasting state can be drawn from the records of those exposed to cold and hardships after shipwreck. It will be at once apparent that the amount of energy employed in maintaining the temperature of the body must be very much greater in warm-blooded than in cold-blooded animals. Indeed, in the latter class, where the temperature is at most only a few degrees above that of the surrounding atmosphere, waste of tissue for the production of heat is practically in abeyance. The same may also be said of hibernating animals, which may be regarded during their winter sleep as cold-blooded. For this reason, and because during certain periods their movements are by no means active, cold-blooded animals can endure very prolonged periods of inanition. In the case of some, months, and even apparently years, may pass without a cessation of the vital processes.

When we come to consider the physiology of fasting more closely, we find that the amount of waste of the various tissues of the body is by no means equal. The following figures, indicating the percentage loss of various tissues in an animal

dying of starvation, are taken from Voit's article in Hermann's *Handbuch der Physiologie*:

|                            |              |
|----------------------------|--------------|
| Fatty tissue lost.....     | 97 per cent. |
| Muscle.....                | 31 "         |
| Blood.....                 | 27 "         |
| Brain and spinal cord..... | 3 "          |
| Heart.....                 | 3 "          |

We thus see that the more essential tissues feed upon the less essential, and that the fats of the body are the great source of nourishment during inanition. As long as a fair amount of fat remains in the body, the muscle can undergo its chemical changes, disintegrating and yielding energy, but always again undergoing a process of reconstruction. Whenever the fat is used up, we find that a rapid disintegration of muscle-substance without reconstruction occurs, and death rapidly ensues. The onset of this condition is indicated by a rise in the excretion of nitrogen in the Urine (q.v.). In dogs this stage is reached in about thirty days.

Jacques undertook a voluntary fast of thirty days at Edinburgh in 1888, and at London one of forty-two days in 1890, and of fifty in 1891. Success fasted forty days in 1890.

In regard to the symptoms observed during starvation little need be said, since in most cases they are due rather to the conditions which have led to or which accompany the fast. The sensation of hunger is a prominent symptom during the earlier days, but appears to diminish. Emaciation is, of course, invariable—the skin feeling harsh and dry from the loss of subcutaneous fat. The temperature falls below the normal, and lassitude and finally torpor supervenes before death, which appears to occur simply from asthenia.

In treating such a case, food must be administered with care, in small quantities at a time, and in a digestible form.

**Fast and Loose**, the name of a cheating game, also called *Pricking at the Belt*, which appears to have been much practised by the Gypsies in the time of Shakespeare. The following is Brand's description: 'A leathern belt is made up into a number of intricate folds, and placed edgewise upon a table. One of the folds is made to resemble the middle of a girdle, so that whoever shall thrust a skewer into it would think he held it fast to the table; whereas, when he has so done, the person with whom he plays may take hold of both ends, and draw it away.' The game is still practised at fairs, races, and similar meetings under the name of *Prick the Garter*; the original name, in the phrase 'to play *fast and loose*,' has gone into the language to designate the conduct of those whose easy ethics do not forbid them to say one thing and do another. See Book XIII. chap. xxix. of Reginald Scot, *The Discoverie of Witchcraft* (1584).

**Fasten's E'en.** See **SHROVETIDE**.

**Fasti** (Lat. *Dies fasti*), those days among the ancient Romans on which it was lawful to transact legal or public business, in opposition to *nefasti*, on which it was not permitted. But the sacred books, in which the lawful days of the year were marked, were themselves denominated *fasti*, and the term was employed, in an extended sense, to signify various kinds of registers, especially the *Fasti Sacri* or *Kalendares*, and the *Fasti Annales* or *Historici*.

The *Fasti Kalendares* or calendars of the year were kept exclusively by the priests for about four centuries and a half after the building of the city. The appearance of the new moon was proclaimed by a pontifex, who at the same time announced to the people the time which would intervene between the Kalends and the Nones. On the Nones the country-people assembled for the purpose of learning from the Rex Sacrorum the various festivals of

the month, and the days on which they would fall. In the same way those who intended to go to law learned on what days it would be right (*fas*) to do so. The mystery with which this lore was surrounded, for purposes of power and profit, by the favoured class was dispelled by Cn. Flavius, the scribe of App. Claudius Cænes, who surreptitiously copied from the pontifical book the requisite information, and published it to the people in the form. Consequently time-tables (*fasti*) became common, very much resembling modern almanacs. They contained the days and months of the year, the Nones, Ides, lawful and unlawful days, &c., astronomical observations on the rising and setting of the fixed stars, the commencement of the seasons, brief notices concerning the introduction and significance of certain rites, the dedication of temples, the dates of victories, disasters, and the like. In later times the exploits and honours of the imperial family were duly entered in the calendar. The celebrated *Fasti* of Ovid is a sort of poetical year-book or companion to the almanac, as arranged by Julius Cæsar, who remodelled the Roman year.

Several very curious specimens of *fasti* on stone and marble have been discovered, of which the most remarkable are the *Kalendarium Maffieianum* (so called from its first possessor), upon almost all the days of the year; the *Kalendarium Prenestinum* of Varrus Flaccus, discovered in 1770 at Preneste, containing the months January to April and December; the *Kalendarium Vaticanum* (March, April, August), *Venusinum* (May, June), *Esquilinum* (May and June), and *Farnesianum* (February and March). These are printed in vol. i. of Mommsen's *Corpus Inscriptionum Latinarum* (Berlin, 1863), in which the Roman calendar for almost the complete year is elucidated.

The *Fasti Annales* or *Historici* were chronicles containing the names of the consuls and other magistrates of the year, and an enumeration of the most remarkable events in the history of Rome, noted down opposite the days on which they occurred. From its application to these chronicles the word *fasti* came to be used by the poets as synonymous with historical records. Of these fragments have come down to us, of which the most important are the so-called *Fasti Capitolini*, discovered in the neighbourhood of the ancient forum in the 16th and 19th centuries. See *CALENDAR*; also Boor, *Die Fasti Censorii* (1873), and Wehrmann, *Die Fasti Prætorii* (1875).
